In moving, under the stress of the magnetic field, the armature of an electro-magnet may do mechanical work. The work done will, of course, be the product of the displacement into the average force. One is naturally led to institute a comparison between the work done in the stroke of an ordinary steam-engine piston and the work done in the stroke of the armature of an ordinary electro-magnet. In neither case is the force uniform from end to end of the stroke. In the case of the engine piston the pressure rises very suddenly at the beginning of the stroke, remains at its maximum for but a very short period, then falls continuously to the end of the stroke, the precise manner of diminution being dependent upon the mode in which the valve is constructed and adjusted, and upon the conditions of supply generally. In like manner the magnetic stress which urges the armature, varies from end to end of the stroke, but in a wholly different manner. At the beginning of the stroke, when the armature is at some distance away from the fixed core, the stress is small. As it approaches, the magnetic field between them becomes more intense, and the stress, which is proportional to the square of that intensity, grows greater, becoming a maximum at the point of nearest approach at the end of the stroke. The range of motion in the case of the ordinary electro-magnet is extremely limited, measurable in tenths, or more ordinarily in hundredths only, of an inch. This is due simply to the smallness of the stress when any considerable thickness of air is interposed. Herein arises so serious a disadvantage in the mechanical problem of utilising electro-magnets for motive power that the late Robert Stephenson once gave this as an emphatic reason why electricity could never compete with steam power. Many devices have been suggested for increasing the range of action of electro-magnets, of which more must be said presently. The coil-and-plunger form of electro-magnet, which has a much greater range of motion though with feebler average force, presents a still greater similarity to the cylinder-and-piston mechanism of the steam engine. In this case the length of stroke and the distribution of the force between the beginning and end of the stroke depend not only on the length of the tubular coil but on the length and shape of the plunger. With a cylindrical plunger of soft iron of a length greatly exceeding that of the tubular coil, the pull increases gradually as the end of the plunger enters the mouth of the coil, becoming a maximum just as it emerges at the further end, and thence falls off again rapidly. If plungers are used not greater than the length of the coil, they reach the position of maximum pull when they are immersed to about half their own length into the mouth of the coil. A simple way of testing the fact is afforded by hanging the plunger to an ordinary spring balance, and noting the pull exerted by the coil as the plunger is immersed to various depths, as in Fig. 1. A very short cylinder or a sphere of iron is only pulled just as it enters the mouth of the coil. With coned plungers the range is extended, long coned plungers being pulled with a force that increases even after their tip has begun to protrude through the end of the tubular coil.

It is extremely important to note that whereas the steam cylinder is, in almost all modern engines, the electro-magnet is, in all ordinary cases, a single-acting mechanism. The armature is drawn magnetically up, but not driven magnetically back. It is simply allowed to return, the electric current being cut off to enable it to move away. The only exceptions to this rule are to be found in the few cases where so-called *polarised* armatures are used; that is to say, armatures previously magnetised in a particular direction. These can be alternately attracted and repelled by reversing the direction in which the current circulates around the electro-magnet core.

This analogy between electro-magnet and steam cylinder is no unimportant one. To the electric engineer the electro-magnet with its armature constitute the central organ of all electric machinery. Just as the mechanical engineer must acquaint himself to the last detail with all that goes on in the cylinder, must experiment and study, by the aid of indicator diagrams, the expansion of the working agent, the effect of the lap and lead of the valves, of fluid friction in the port-holes, of rapid condensation of the exhaust steam, and the like, so the electrical engineer must resort to experimental study, and use diagrams to enable him to follow the operations of the electro-magnet, must watch the progress of magnetic saturation of the core, ascertain its retentiveness, observe the effect upon its performance of varying the configuration of the parts, of throttling the induction by insufficiency of section, and the like.

*The Principle of Reversibility.*

Far as these analogies have been traced, they may be carried one stage further. The principle of reversibility which holds good of the steam cylinder, holds good of the electro-magnet also. In its usual function the cylinder and piston mechanism of the steam-engine serves to convert the latent energy of the steam under pressure into mechanical work; but the very same mechanism is capable of serving the inverse function of employing mechanical power to compress steam, air, or any other gas. The pump is the inverse of the engine in its functions; its action is simply the action of the engine reversed. From the thermodynamic point of view the action is equally inverse. In the engine heat is converted into work, or in other words, entropy is let down from a high temperature to a low one, thereby furnishing energy to a mechanical system. Reversing the action, energy furnished by a mechanical system is employed to transfer entropy from a low temperature to a high one, and the apparatus becomes a machine for artificial refrigeration.

Turning to the electro-magnet, energy furnished by letting electricity pass from a high potential to a low one is employed, magnetically, to produce a mechanical motion, and so to perform work. Reversing the action, energy furnished by a mechanical system is applied to an apparatus consisting of magnetic circuits and copper wire coils, which thereby becomes a machine for pumping up electricity from

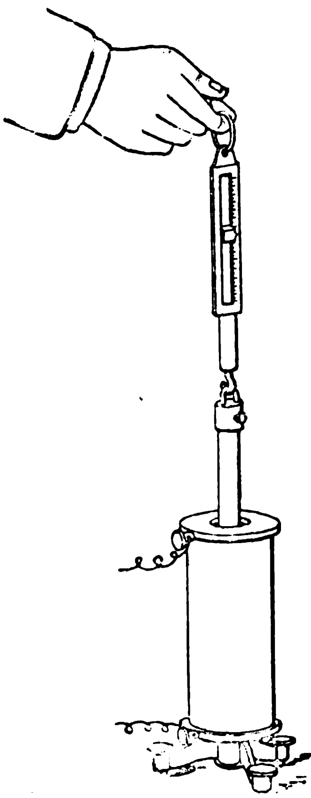

Fig. 1.

a low potential to a high one; in other words, it become a source of electric currents. The modern dynamo machine is simply an electric engine—a combination of iron cores and copper coils—capable of serving in either of two functions, as generator or as motor, each the inverse of the other.

*Relation between Magnetising Force and Magnetism.*

It is time to return to the principle of the magnetic circuit, briefly enunciated above, and to re-state it in more precise terms. The number of magnetic lines that will be evoked in any given magnetic circuit is directly proportional to the circulation of the surrounding electric current, and inversely proportional to the magnetic reluctance of the iron and air-gaps of the magnetic circuit. It is usual to specify the circulation of current in *ampere-turns*, meaning thereby the product of the amperes into the number of turns of wire in the coil. The reluctance of the magnetic circuit must usually be calculated in parts, to be added subsequently together, allowance being made for leakage of magnetic lines. The reluctance of each part is proportional directly to its length, inversely to its cross-section, and inversely also to its permeability.

All known substances possess permeability, none having yet been discovered that is impermeable to the flux of magnetic lines. The vast majority of media—including air, all gases, all liquids, all organic solids, all compound bodies save three, all metals save three—have a small and constant permeability, not differing sensibly from that of vacuum. The exceptions that have a relatively large and variable permeability are the three metals—iron (including steel), cobalt, and nickel (possibly also chromium and cerium), together with some of their alloys, and the compounds, loadstone (triferric tetroxide), pyrrhotine (magnetic pyrites), and ferroso-cobaltic oxide. Of these only iron need be here considered.

*Magnetic Qualities of Iron.*

Different specimens of iron differ widely in their permeability. Moreover, the permeability in any given specimen of iron varies with its degree of magnetic saturation; a sample that is already well magnetised being much less permeable than one that is less highly magnetised. Approximately the permeability of a specimen is proportional to the difference between the actual magnetic flux through it, and the maximum flux that can be forced through it. A certain specimen of annealed wrought-iron for example, which became saturated to a practical maximum when permeated with 18,000 lines per square centimetre, had at 17,000 lines per square centimetre a permeability of 161, and when only pushed to 16,000 lines per square centimetre, had a permeability of 320. The intensity of the magnetising force at any point, usually denoted by the letter H, is often expressed by saying that it would produce H magnetic lines per square centimetre if acting on an air core. Now, if the space were occupied by a core of iron instead of air, there would be produced by the same magnetic force a larger flux of magnetic lines per square centimetre. This larger number expresses the degree of magnetisation of the iron (also called the magnetic induction in the iron); it is denoted by the letter B. The

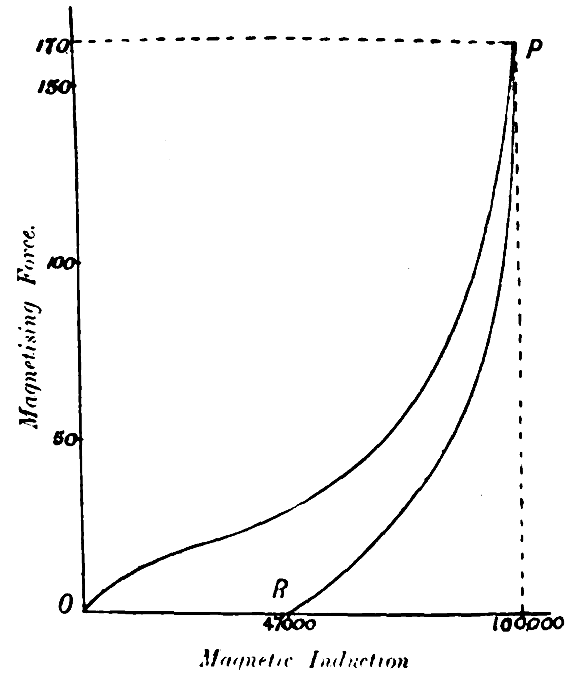

Fig 2.

ratio of B to H expresses the permeability of the material at that particular stage of magnetisation. To ascertain the magnetic properties of any specimen, a series of observations must be made with various intensities of magnetic force. In any complete research a number of such series have to be made at different temperatures; as certain materials, notably the alloys of iron and nickel lately investigated by Dr. J. Hopkinson, change their magnetic properties much when heated. A series of such observations made by Dr. Hopkinson on a specimen of wrought-iron are represented by the curves in Fig. 2. Two liberties have been taken with this figure. In the first place, the numbers plotted out are the numbers of magnetic lines per square inch, instead of the usual numbers per square centimetre. In the second place, the magnetic forces are plotted vertically, and the resulting induced magnetisation horizontally, the converse to the usual mode of plotting. The curve that starts from O represents the set of observations made with magnetic forces gradually increasing to about $H_{\prime\prime} = 170$, when the resulting number of magnetic lines per square inch in the iron is about 100,000. It will be noticed that when the magnetising force $H_{\prime\prime}$ approaches the value of 100, the curve becomes very steep, any further increase producing relatively little increase in the magnetisation. The second curve represents the result of then decreasing the magnetising forces back to zero, when there remain behind a

residual magnetisation of no fewer than 47,000 lines per square inch. To remove these would require the application of a reversed (or negative) magnetic force of about $H_H = -13$.

Applying the principle of the indicator diagram to these curves, it will be seen that the area below the first of these curves, down to the zero line, and bounded on the right by the ordinate of the point P, represents the integral product of magnetic force into magnetisation, and is consequently proportional to the work done (per cubic inch of the iron) in bringing about the magnetic state of things implied by the position on the diagram of point P. Similarly, the area under the descending curve represents the work restored in the demagnetising of the specimen down to the state of things represented by the point R, when the magnetising force has been removed. The narrow area enclosed between the curves represents the work not so restored, and for the expenditure of which the residual magnetism is all that there is to show. If the magnetising forces are carried through a complete cycle of alternations from $+H_H$ to $-H_H$ and back, the resulting magnetisation goes through a corresponding cycle, with the result that a definite closed area is completed between the curves in the diagram (Fig. 3). Were there no lagging in phase of the magnetisation behind that of the magnetising force, the ascending and descending curves would coincide instead of enclosing an area. Some specimens of magnetic material—particularly pure octahedral crystals of magnetic iron ore—show no such lag. They exhibit practically no residual magnetisation. The phenomena of lag have been studied particularly by Prof. Ewing and by Dr. John Hopkinson, to the former of whom we owe the term *hysteresis* to denote this lagging

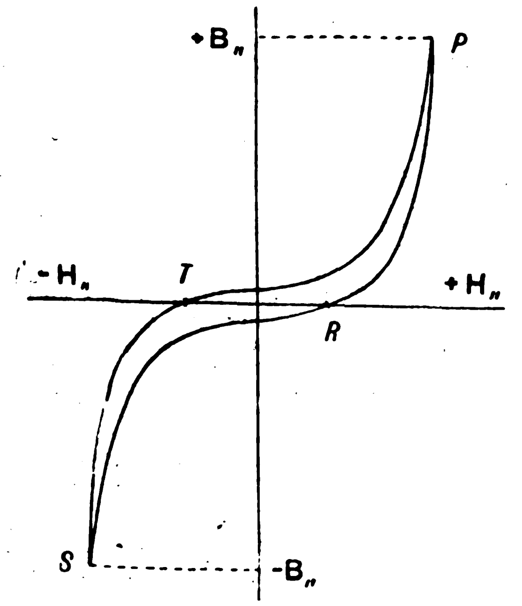

Fig. 3.

of effects behind the phase of their causes. When a specimen of iron is carried through such a complete cycle of magnetisation, and brought back to the same magnetic condition as that from which it started, there is nothing to show in the way of residual magnetisation; for in half the cycle work is spent in producing such a residuum, and in the other half work is spent also in destroying the residuum. In fact, the enclosed area represents the work lost by hysteresis. Its only effect is to heat the material; hysteresis being in magnetic problems as molecular friction in the problems of elasticity, always the cause of work being wasted.

*(To be continued.)*

**Royal Institution.**—The following are some of the Friday evening lectures which have been arranged for before Easter. On January 23rd Lord Rayleigh will lecture on "Some Applications of Photography;" Prof. J. W. Judd will, on February 6th, lecture on "The Rejuvenescence of Crystals;" while on Friday, March 6th, and on Friday, March 20th, respectively, Dr. Fleming will discourse on "Electro-magnetic Repulsion" and Prof. Ayrton will tell us all about "Electric Meters, Motors, and Money Matters." Commencing on Saturday, February 14th, Lord Rayleigh will deliver a course of six lectures on "The Forces of Cohesion."

## TELEGRAPHIC TRANSMISSION ON LONG SUBTERRANEAN LINES WITHOUT THE USE OF RELAYS.*

As is generally known, telegraphic transmission is not so easily carried out on long subterranean as on aerial circuits. On underground circuits of less than 190 miles retardation phenomena are scarcely noticeable, but for greater distances than this, electrostatic effects become increasingly troublesome, and since the underground telegraph system of Germany has assumed large proportions, the authorities have tried to annul these pernicious phenomena in a variety of ways. For instance, a short path to earth has been offered after each signal at either end of the line to the discharge current; alternate current working has been attempted, and condensers have been used to neutralise the charge of the cable by one of the opposite sign from the condensers. None of these methods, some of which involved the addition to the

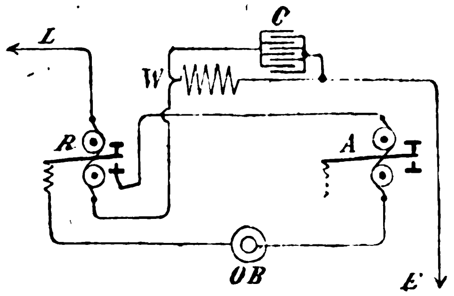

Fig. 1.

ordinary instruments of costly and cumbersome apparatus, fulfilled the desideratum of enabling messages to be transmitted as quickly and clearly as on overhead circuits of equal length. The most efficacious method was considered to be the employment of relays at every 100 or 150 miles, and even then the rate of transmission was considerably less than on overhead lines. Recently an apparatus was devised by Delany, of New York, which, although intended primarily for use on long submarine cables, seemed equally suitable for subterranean work. By means of the Delany key (for full illustrated description, see *The Electrician*, Vol. XXI., p. 242) we can, it is true, send Morse signals much quicker than has hitherto been possible, but it necessitates the employment of complicated apparatus, liable to get out of order. The engineering staff of the German Post Office, therefore, who had been ordered to investigate the practical value of the Delany device, set to work to try and obtain the same result in a simpler manner and without altering the instruments at present in use. Now, augmentation of the speed of transmission depends on realising three conditions: (i) Decrease of battery resistance;

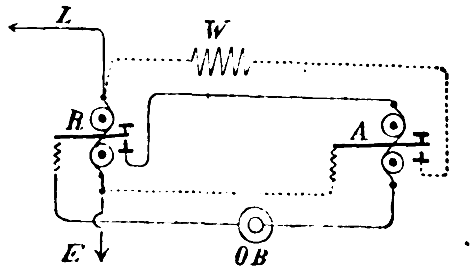

Fig. 2.

(ii) Acceleration of the discharge of the cable; (iii) Compensating the self-induction of the receiving apparatus. It is easy to fufil the first condition, either by arranging the cells in parallel or by using secondary cells. The disturbance produced by self-induction is connected with the effect of the cable discharge. The tongue of a sensitively adjusted relay should fall and close the local circuit as soon as the first part of the current reaches the receiving end; but the release of the tongue is retarded by the discharge current, and this retardation is prolonged by self-induction. To neutralise these effects recourse may be had to an old device proposed by Maxwell.

In this arrangement a resistance W, in shunt with a condenser C, is placed between the receiving relay R and earth E (Fig. 1). The resistance must bear a certain definite relation to the capacity of the condenser, which relation has to be determined by experiment. The installation of a condenser in the first place permits of a more rapid rise of current at the receiving end, since it fulfils during the first instants of charging the functions of an earth. The attraction

* Abstract of a paper read by Herr Grawinkel, chief engineer to the German Post Office, before the Berlin Electro-technical Society.

Digitized by Google

of the tongue of the relay is thus favoured. Moreover, the discharge current of the condenser and the "extra-current" from the line are mutually destructive, and the disappearance of the magnetism is thus accelerated.

In the first experiment with this arrangement the Berlin-Hamburg cables were looped, forming a circuit 272 miles and having a resistance of 5,151ω and a capacity of 150 microfarads. In the second experiment the Berlin-Frankfort cables were looped: length 350 miles, resistance 4,279 ohms, capacity 120 microfarads. The resistance of W was 9,430 ohms, and the capacity of C 20 microfarads. Fifty Tudor accumulators were employed, reinforced by 40 primary cells. In the first case 300 primary cells arranged 100 in series and three in parallel were used.

So far as speed of transmission was concerned these experiments were satisfactory. Representing the ordinary rate of transmission of Morse signals, without translation, by 100, the speed of transmission when a shunted condenser was used was 131, or nearly 30 per cent greater. It must, however, be remembered that the ratio of W to C has to be determined in each individual case, so that the use of this method does not tend to certainty of transmission, and it may derange the working of the line. Attempts were, therefore, next made to attain the same increase of speed without condenser, and this result was finally attained by the very simple arrangement shown in Fig. 2.

In shunt with coils of the relay a variable resistance W is placed, and this resistance only comes into play when the "inker" operates. The effect of this arrangement is to accelerate the discharge of the line. When the current wave at R has attained sufficient strength to work the relay, the Morse recorder A operates. The remainder of the wave then divides, some going to E *viâ* W. The current in R is of course diminished the smaller W is made, and the release of the tongue is thus hastened. The tongue must not, however, be released before a proper Morse signal has been recorded, and the resistance of W must, therefore, be properly proportioned to that of R. It has been found useful to prolong the effect of the shunt circuit, which can be effected by fixing a light spring to the lower end of the "inker" lever so as to hasten the closing of the shunt circuit. If this circuit is of too low resistance the tongue of the relay is released too soon, while if the resistance of W is properly adjusted the current flowing in R, together with the "extra current," act long enough to allow a signal to be produced.

Favourable results have been obtained with this arrangement in transmitting Morse signals without translating devices over a subterranean line connecting Berlin and Frankfort. The relative speeds were: ordinary Morse, 100; condenser and resistance method, 131; arrangement shown in Fig. 2, 145. Further tests of this method on underground lines have shown that Morse signals can be transmitted at the same rate as on overhead circuits up to distances of more than 375 miles, and that on longer an increase of speed of 30 per cent. is obtainable, when compared to the old device of fixing relays at every hundred miles. When a line is more than 625 miles (1,000 kilometres) long it is advisable to instal midway a relay on the shunt principle. One circumstance which contributes in a great measure to acceleration of transmission is that it is no longer necessary to employ such sensitive relays as formerly, sticking of the relay tongue and the consequent blending of signals is thus avoided. Readjustment of the relay is also less frequently needed. Let us hope that this new device may be equally applicable to the transmission of Hughes signals on underground circuits.

## THE OPERATION OF ELECTRIC RAILWAYS.*

In spite of the fact that over 200 electric railroads are to-day in actual operation, comparatively little concerning the practical details of operation has been made known. In the present state of the art railway managers go in for results rather than methods, and in spite of some crudities the results have generally been extremely satisfactory. We have much to learn, however, regarding the true inwardness of electric railway operation. With a view of finding out in a general way as many facts as could be readily obtained with respect to the operation of the modern electric railroad, the *Electrical World* recently sent out to a very large number of electric railway managers a blank containing a list of questions, with the request that the questions be answered and the blank returned. The questions asked were the following:—

1. What system do you use?
2. How many miles of track have you?
3. How many motor cars?
4. What is the average daily mileage per car? Total mileage?
5. What is your steepest grade; does it trouble you in bad weather?
6. What is the total capacity of your dynamos?
7. What is your usual actual station voltage?
8. What is the make and rated horse-power of your engine or engines?
9. Have you tried track or power brakes; if so, with what result?
10. Have you tried cars fitted with a single motor, and with what result?
11. What increase of gross receipts has followed the adoption of electricity?
12. Have the total expenses increased or decreased, and to what extent?
13. What proportion of total expenses is due to repairs on your equipment?
14. What is the average cost of power per car per day?
15. What kind of gearing do you prefer, and what is the usual life of a set of gears?
16. What damage has been done your cars, lines, or stations by lightning?
17. How do the citizens regard the introduction of overhead wires?
18. Do your lines cause trouble with the telephone service, and is the most of it due to earth or to induction?
19. Have any serious shocks been received by *employés* or public?
20. What do you consider the weak point of the particular system which you use?

* From the *Electrical World* of New York.

These last 10 questions were strictly confidential, and consequently in what follows no company or system will be referred to.

Up to date 85 replies have been received from all parts of the country and practically all the systems in use. Eight systems are included in the list of replies; of these 33 were from Thomson-Houston roads, 25 from Sprague, 5 from Rae, 3 from United Electric Traction Company, 2 each from the old Daft and the Short roads, and 1 each from Van Depoele and storage systems. Detailed statements of mileage have been received from 64 roads. Of the figures given the largest was 150 miles per day, reported by two roads. Three others were close behind in the race with 140, and from that the figures run down to as low as 43, most of them, however, ranging between 90 and 100. The two highest figures came from two different systems—one of them a Rae road operating five cars over nine miles of track, the other, a Thomson-Houston road, with 44 motor cars and 25 miles of track. Taking the average of the 64 roads, the mean daily mileage per car is 101. This large figure may be borne in mind with reference to the answers of some of the succeeding questions, as it has an important bearing both on the increased receipts and the occasionally increased expenses.

Eleven per cent. is the heaviest grade reported, though a number of roads are not far in the rear with 10 and 9 per cent. grades. As regards any trouble experienced in running up these heavy grades, the uniform experience has shown that there is very little difficulty encountered, with a judicious use of sand for occasional aid. If we may judge anything by the results obtained with locomotives, the coefficient of adhesion is in excess of 20, although it is quite probable that in a motor car the weight may not always be distributed to the best advantage. At all events, there is every reason to believe that a motor car alone can mount a grade decidedly steeper than any that have yet been attempted. Of course, the use of trailers brings down the maximum possible grade, but the experience of the numerous roads that have reported makes it tolerably evident that 10 per cent. is quite practicable in any ordinary weather.

The total capacity of the dynamos brought out some rather instructive replies, so far as the question of efficiency is concerned. The allowance of power in station capacity per car varied considerably, ranging from less than 10 to over 20 horse-power for each motor car. Roads showing the latter figure might reasonably be expected to show considerable loss in the station from habitual underloading of the dynamos, especially as most of these were rather small roads, where the variations in power are necessarily great and the average load consequently light. Where a small road provides 20 electrical horse-power per car the dynamos are necessarily worked at considerable loss of efficiency. Although the indications thus point to habitual underloading of the dynamos, this state of things is far more noticeable in the matter of engines It is not at all uncommon to find engines reported having a rated capacity 50 per cent. in excess of the full rated capacity of the dynamos. Inasmuch as the full capacity of the engine is usually much greater than its rated capacity—the latter being in general engineering practice based on a cut-off of about one-fourth—it is safe to say that the loss from engine to electrical energy on the line—in other words, loss of efficiency—is much greater than it should be or will be as the real condition of things is better understood.

The prevalence of this state of things is due probably to a large variety of causes. There is a certain feeling that an engine must be big enough to do considerably more work than it will be ever called upon to do, and at the same time it frequently happens that in equipping a power plant allowance is made for the possible contingency of increase in plant at some future time. Under certain circumstances it may be advisable to put in a large engine with this in view, but there are plenty of cases where the increased cost of fuel entailed upon the system by this arrangement would more

than pay for an extra engine. A 50,000-watt dynamo, unless it is the intention to overload it, does not call for an 80 or 90 horse-power engine, provided the latter is properly constructed. The nominal horse-power reckoned as usual at one fourth cut-off, is about the point of maximum efficiency of engines with the steam pressures generally used, and underloading has a worse effect on economy of fuel than overloading. It is safe to say from the figures that have been brought in that the average efficiency of the station, that is, the ratio between the indicated horse-power of the engine and the electrical horse-power of the line, is from 10 to 25 per cent. less than is practicable with a more economical design. Practice is apparently improving, but there is much left to be desired yet. One of the worst cases in the matter of station efficiency was a road operating three motor cars and provided with an engine of 125 horse power. It is safe to say that under these circumstances, particularly as the grades upon the road were light, not more than one-third of the indicated horse-power at the engine appears as electrical energy on the line, and the total efficiency from engine to car wheel cannot well exceed 20 per cent. There are other cases very nearly as bad. A far better specimen of practice is found in several roads that report compound engines of the same rated capacity with the dynamos, and a fine example appears to be under way in a 25-car road having dynamos of a capacity of 420 horse-power operated by a Corliss engine rated at 300. This arrangement means that the full capacity of the engine, assuming the usual standard cut-off, would be very nearly the full capacity of the dynamos, which in a road of that size is certainly good practice.

With reference to the question of track or power brakes no very satisfactory results have appeared.

With regard to question 10, a considerable proportion of the roads that have reported up to date have had some experience with cars deliberately fitted with a single motor, and the general consensus of opinion seems to be that such an arrangement is advantageous where the grades are not heavy. One large Sprague road is fitted entirely with single motors, and reports the best of success. There is every reason to believe, theoretically and practically, that where it is possible to do the work with a single motor the arrangement is most desirable.

Next passing to the second series of questions, there is but one verdict concerning the effect of electricity on the earnings of the road. Of course a considerable number of the systems which replied to the questions were started as electric roads, and consequently could report nothing. But in every case where there was any response from roads which had previously used horses the increase in gross receipts was most marked, ranging from 10 to 500 per cent. Most of the figures showed at least double the traffic that had previously been obtained. This is only what might be expected in view of the very considerable increase in mileage. The adoption of electricity practically doubles the carrying power of a road.

With respect to the total expenses under the electric systems, three or four reports of decrease came in, but the vast majority showed a slight increase. Not enough figures were obtained to permit of a fair average, but 10 per cent. of increase in total expenses would be a fair estimate. To off-set that we have something like 100 per cent. increase in receipts. This is as might be expected; a very great increase in total mileage and carrying capacity is naturally followed by some little increase in wear and tear, and it is not at all remarkable that the cases of actual decrease have been comparatively few. It must be noted, however, that the actual increase in expenses is so small that there is the best of reason to believe that the balance will universally swing the other way as the conditions of economical operations come to be better understood. The increase in net receipts in every case is most marked.

With respect to the cost of power per day, a great many roads were not in a position to give it with any accuracy. Thirty-eight full replies, however, were received covering this point. They ranged from 50 cents per car per day—to which was added the sententious remark, "We burn culm"—to $7 per day in a portion of the country where coal is necessarily very high. The average cost of power per day in 39 electric roads of all sizes, systems, and in all parts of the country, amounts to $2.13 per car per day; and, reducing this to car miles from the figures obtained from these same 39 roads, the average cost of power per car per mile appeared to be 2.024 cents—certainly not an excessive figure.

Comparatively few replies were obtained to question 13, only 20 of the systems giving a definite response. These 20 presented the widest variation, the figures ranging from 1 to 50 per cent. The general average of the 20 indicated that repairs amounted to 18 per cent. of operating expenses.

In the matter of gearing it is only too evident that there is much improvement to be made. All the companies which answered this question at all seemed to be of the opinion that our present system of gearing is not what it should be. Four to six months seemed to be the general life of a set of gears. That stripping has not yet been overcome is evidenced by one remark to the effect that the life of a gear wheel varied from two minutes to a year.

The answers to the 16th question, too, bore on this question of repairs, for a considerable number of reports of serious damage from lightning came in; field coils, motor armatures, and generator armatures share about equally in this particular.

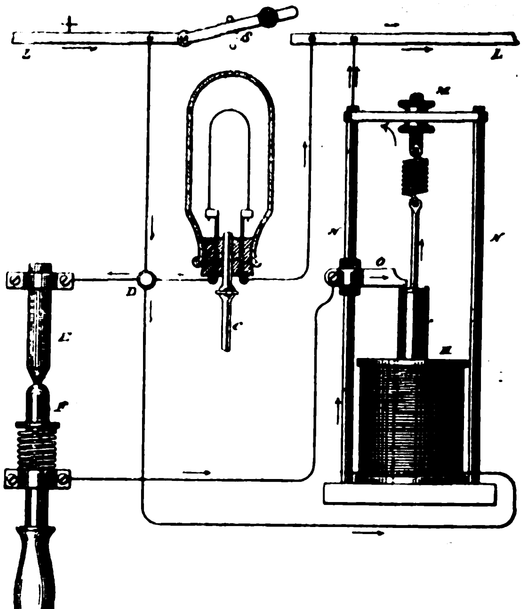
Question 17 was answered favourably in nearly every case. Throughout the country apparently the people are becoming reconciled to the overhead wires, regarding them as certainly desirable in default of any more convenient system of supply.

With respect to the trouble with the telephone service little information was obtained—none of it of value; and the same is true with regard to question 19. No serious results of shock were reported in any case, bearing out the general experience that the current used on street railway lines is not of sufficient voltage to be dangerous.

Question 20 might have been productive of very instructive results, but as a matter of fact the inferences that could be most clearly drawn from the replies received were that the weak point of the modern electric railroad on any and every system is the gearing. In addition to this, there were complaints of badly-constructed armatures and of great susceptibility to the destructive effects of lightning. It is unfortunately only too evident that lightning arresters do not always do their work. The large shunt-wound generators used in railway plants are particularly thin-skinned as regards lightning, so far as we can judge from the results of experience, and arresters which work successfully in other cases often fail here.

## AUTOMATIC FILAMENT-FLASHING APPARATUS.*

The object of the device illustrated in the cuts is to so control the filament flashing process that when the filament reaches the desired resistance it will be automatically cut out of circuit. In using this apparatus, which is the invention of Hermann Lemp of Hartford, Conn., a constant current is employed. A number of the devices for flashing two or more filaments may be therefore arranged at the same time in series.



Referring to the cut, the construction of the device will be readily traced out. The operation of the apparatus is as follows: When the switch S is thrown open, the current splits at D into three portions. One of the portions passes through the carbons E F to the insulated contact-arm O, and thence by way of the core and spring to the frame N, and then to the negative terminal of the line L. This circuit, when intact, is of low resistance. Another portion of the current passes by way of the high-resistance solenoid H, to the frame N to the negative terminal of the main line. The third portion of the current passes through the filament B to the same terminal. The arrows in the figure indicate the paths of the current.

When it is required to flash a filament, the parts are in the position shown in the drawing, an initial filament having been sealed in the globe and a hydrocarbon vapour or liquid passed into the globe through the pipe C. The carbons, E and F, are now separated so as to draw an arc of gradually increasing resistance. This forces the current through the solenoid H, and through the

* From the *Western Electrician*.

Digitized by Google

filament. The latter is now rendered incandescent by the passage of the current and decomposes the hydrocarbon. This action causes a deposit to be made on the filament. The solenoid H also becomes energised, drawing down the core and breaking the contact at O. The continuity of this circuit is thus destroyed, as is the arc between the carbons. The filament at the start being at its highest resistance, causes the greater part of the current to pass through the solenoid and draw the core down to its lowest point. As the deposit upon the filament decreases its resistance and the difference of potential between its terminals also decreases, the core in H will gradually rise until it reaches its highest point. It will then come in contact with the insulated arm O, and automatically shunt the filament, the carbons in circuit having been allowed to assume their normal position after the arc goes out. This operation may be timed by adjusting the apparatus so that the filament will be shunted when it has reached any desired cross-section. The thumb-nut N can be regulated so as to produce this effect, or the solenoid H adjusted for this purpose. It is necessary that the filaments be of a certain standard length; otherwise the variation in length, giving rise to a difference of resistance, would interfere with the successful operation of the apparatus. This method the inventor claims makes the flashing of filaments entirely independent of the pressure of the hydrocarbon gas, its temperature, and the time of flashing.

## SABLE ISLAND.

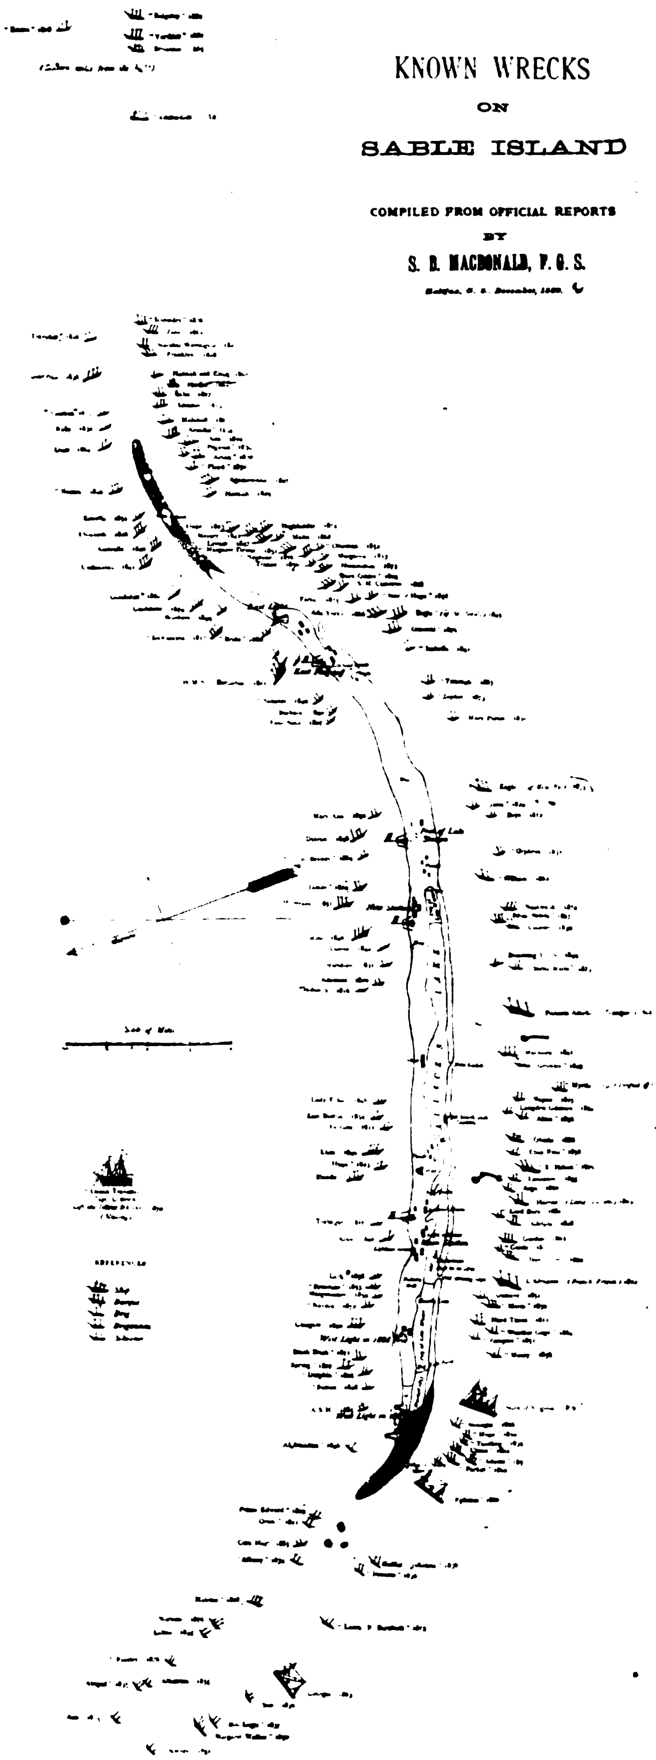
In the course of a review of the telegraph system of Denmark in these columns some months ago, it was pointed out how much credit was due to the Danish Government for connecting the lighthouses and shipping and fishing stations by telegraph and telephone in the interest of the maritime population. We give on the opposite column a sketch of Sable Island, the "graveyard of the Atlantic," showing the various *known* wrecks which have taken place there in past years. Our object in calling attention to the subject at the present time is to urge upon the Imperial and Canadian Governments the desirability, and even necessity, of connecting this dangerous sandbank, for it is little more, with the Government telegraph system, so that help might be promptly despatched to the scene of a wreck or other maritime disaster, in order to effect the saving of life and property when emergencies arise.

The following description of Sable Island has, at our request, been kindly supplied by Mr. F. N. Gisborne, the head of the Canadian Government Telegraph Department, and will be read with interest by many of our readers.

The island is situated in the Atlantic Ocean, about 85 miles from White Head and 150 miles north-eastward of Halifax, Nova Scotia; is a long, narrow, sandy elevation, formed of two nearly parallel ridges, somewhat in the form of a crescent, concave to the northward, and meeting in a point at either end, with sand bars or spits running out from them, over which the sea breaks with great fury during stormy weather. It is about 22 miles in length and scarcely exceeds one mile in width in the widest part. In some places it is wholly or partially covered with coarse grass, in others thrown up into sand hills, none exceeding in height 75ft. above high water. In the middle of it, and between the ridges, there is a long, narrow salt-water lake, about 14 miles long, towards which, on the south side, the sea is gradually encroaching, sweeping, during heavy gales, completely over the bank of sand which separates it from the ocean.

When seen from the north at a distance of ten miles, the island presents the appearance of a long range of sand hills. From the south the range has a more continuous appearance, and on the west sinks very low. The sand hills have in many places formed steep cliffs next the sea; whilst in others they are covered with coarse grass, and are defended by a broad beach which cannot, however, be reached without passing over ridges of sand covered by only a few feet of water. These ridges, which are parallel to the shore at distances not exceeding one-third of a mile, are dangerous to pass in boats when any sea is running. Spring tides rise about four feet, and the ebb sets to the southward at one and a-half to two knots, and the flood at a much less rate in a contrary direction. At each end of the island are dangerous bars, the north-west bar being dry for three-quarters of a mile, succeeded by nine miles of foaming breakers in rough weather, while the north-east bar is dry for four miles, succeeded by 10 miles of breakers.

There being no harbour of any kind around the island, vessels calling anchor one or two miles distant from the shore, and run for shelter to the mainland or out to sea upon the approach of on-shore winds. A reference to the wreck chart will show how the island is gradually wasting away by the action of the sea at the western end, and extending at the eastern end. The average number of ascertained wrecks on Sable Island for some years past have been two annually; but there is frequently sad evidence of additional losses on the bars in the shape of fragments of vessels, or of their cargoes, coming ashore, and many a good ship has come to an untimely end without a soul who was on board surviving to tell the tale.



Two powerful lighthouses have been erected at either end of the island, and at the central station lifeboats, &c., are maintained. A telephone line connects these establishments; but the main desideratum still lacking is a submarine cable connection with Nova Scotia, say 100 miles in length, by means of which timely notice of

Digitized by Google

**wrecks and required assistance could be given, and one or two trips per annum would provide all necessary supplies for the maintenance of the establishment. It is a source of much surprise in the maritime world that such a modern necessity has not already been provided for by the Imperial and Canadian Governments, and should the publicity which the subject is now likely to receive in this country have the desired effect of securing the establishment of the much-needed cable communication, one of the dread dangers of the deep will be minimised.**

**The cost of 100 miles of cable of a type suitable for the somewhat shallow water, manufactured in England, would be about £15,000, and the expense of laying, if a ship were sent specially from this country for the purpose, say, £5,000. If, however, advantage were taken of a vessel proceeding to repair one of the Anglo-American Telegraph or Direct United States Cable Companies' lines in the neighbourhood, the submerging of the cable in question might be effected for £1,500, making a total cost of, say, £16,500.**

**It may be pointed out that submarine cables are becoming much more costly year by year, owing to the great rise in the price of copper as compared with two years ago and the increasing scarcity of gutta-percha, for which, in the manufacture of cables, no substitute has yet been found.**

## THE RONALD'S LIBRARY.

Many of our readers, and some of its members, have never had an opportunity of visiting the habitation of the Institution of Electrical Engineers in Broad Sanctuary. The Sanctuary was one of the privileged precincts. It was under the protection of the abbot and monks of Westminster. Skelton, the satirist, took shelter here from Cardinal Wolsey. The

privilege survived the Reformation, and many of the houses which composed the precinct were not taken down till 1750. The offices of the Institution consist of three rooms, soon to be vacated: the secretary's private room, the Council room, and the Ronald's Library. The library, bearing the name of its founder, consists of a very fine collection of books on electrical science, and was bequeathed to the Institution. The contents are chiefly of historical interest, and the library is not kept up to date with modern books unless they are presented by their authors. Through the courtesy of Messrs. Cassell and Co., we are able to reproduce an excellent engraving of the Library, which appeared in *Cassell's Family Magazine*.

"May's Popular Instructor for the Management of Electric Lighting Plant." (Frankfort).

## AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December* 12, 1890.

**The New York Subways.**—The combat between the City Government and the Consolidated Subway Company, on the one hand, and the electric light companies on the other, continues. At a meeting of the Board of Electrical Control, Dec. 10th, the proposition previously brought forward to turn over the low tension subway construction to a new company was brought up, and a resolution granting the consent of the Board of Electrical Control was presented. Before it came up for consideration the Mayor was served with an injunction obtained in the interest of some of the electric light companies, restraining the Board from making any contract with the new company, or from relieving the old company of any of its obligations, or from making any bargain for subways with any person or corporation engaged in the business of supplying electricity in competition with other companies. This is aimed directly at the Empire Company, which is made up, as was mentioned in my last letter, of people interested in the telephone and telegraph companies. Mayor Grant then arose, and moved to fix a new rental for the subways. This was done, and the expected reduction hardly took the form which was hoped by the electric companies. The proposed prices were for 3in., 2½in., and 2in. ducts respectively, at $900, $800, and $700 per month. This proposition is equivalent to continuing the old oppression that has been so bittterly complained of in the past. The municipal authorities have peremptorily refused the bids for city lighting offered by the various companies; they seem to think that they will be able to force by various oppressive regulations the furnishing of light at the same price as before the wires were put underground. If free permission had been granted to the illuminating companies to do their own subway construction, it might have been possible to furnish light at the old prices; but with the ring and the Subway Company united to extort every possible dollar for conduit rents, there is little prospect of any such peaceable settlement. The whole matter will go before the courts for decision, and with a promise of bitter and prolonged litigation.

**Decline in Price of Electrical Stocks.**—Just at the present time there is a serious decline in the price of electrical stock. Large companies and small alike are included in this unhappy movement, and rumoursare flying about that at least one of the important companies is in a very tight place financially. In spite of the good prices obtained for electrical machinery, reckless competition has reduced the funds available for carrying on business. It is an open secret that sales are frequently made on the basis of not more than 25 per cent. in cash, the remainder being taken in bonds of the company to which the apparatus is furnished. This sort of thing cannot go on indefinitely without causing trouble, which has apparently come already.

**The Rochester (N.Y.) Power Station.**—One of the largest power stations in use to-day is that of the Electric Railway Company in Rochester, N.Y., now rapidly approaching completion. The road is operated on the Short overhead system, and the generating station is equipped with machinery of the same make. The building is a colossal one, the dynamo room being over 200ft. in length; it will contain 17 80-kilowatt generators, driven by seven engines, and will furnish power both to railway and to stationary motors. The Short system originally entered the field as an exponent of series traction, but this feature of its work has practically been abandoned, so that at the present time its cars are operated on the parallel system of distribution, like those of all the other American tramway systems.

## VIENNA NOTES.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *December* 20, 1890.

The International Electrical Company of Vienna opened its new central station on November 14th, and current is now supplied every day from 4 o'clock until the morning. The dynamo at work is one of Messrs. Ganz and Company's type A 7 machines, and has a maximum capacity of 200 kilowatts, at 2,000 volts pressure. The other dynamos which are to be put up are of type A 8 of 400 kilowatts. The exciters are also made by Messrs. Ganz and Company, they run at 375 revolutions, and give 150 amperes at 180 volts pressure. The exciters are driven by and coupled direct to Westinghouse engines. The boilers are by Messrs. Steinmüller, and have 243 square metres heating surface. The central station, when completed, will have a capacity of 6,000 kilowatts.

As I have already reported, the Imperial Palace is to be lit by electricity. This will be a very large installation, as the palace contains altogether 93 halls and rooms, of which 52 are to be completed by the end of this year. Glow lamps only are to be used, and they are to be so arranged that all the present costly fittings will be utilised. The lamps are to be so arranged as to look like wax lights. They will be smaller than is customary, and fitted to white wooden stands. Some 5,250 glow lamps will be used for the 93 halls and rooms, and their total candle-power will be 30,000. One hall alone, the Knights' Hall, will be lit by 1,836 lamps.

The Anglo-Austrian Bank have been negotiating with Messrs. Siemens and Halske about taking over all their works in Austro-Hungary. These negotiations are said to be completed, and the Bank proposes forming two companies, one to work Messrs. Siemens and Halske's works and installations in Austria, and one to take over their business in Hungary, specially their electric railway in Budapest.

The town of Trient has a large electric light installation. The power is derived from turbines, the dynamos being coupled direct to them. The installation was put down by Messrs. Siemens and Halske, and it supplies 4,150 glow lamps and 44 arc lamps. The streets are lit by 550 glow and 22 arc lamps. The power being so cheap, it is no wonder that the electric current is being largely used for motors. One mill is being driven by an electromotor of 50 horse-power, and many motors of 2, 1, and even $\frac{1}{10}$th and $\frac{1}{20}$th horse-power are in use.

## CORRESPONDENCE.

### SECONDARY BATTERIES, POSITIVE AND NEGATIVE PLATES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you allow me to call attention to the confusion that arises from the use of the words positive and negative, in reference to the plates of a secondary battery. Strictly speaking, the peroxide plate is the positive plate in the charge and the negative plate in the discharge; and similarly, the grey plate is negative in the charge and positive in the discharge. Hence there is a certain inconvenience in calling either plate by the name of positive or negative, since it is sometimes entitled to the one name and sometimes to the other.

This inconvenience, however, might be borne if all writers used these names in the same way. But such is not the case. Messrs. Ayrton and Perry, for example, in their excellent and valuable Paper, which has lately appeared in your journal, speak of the peroxide plate as positive, and of the grey plate as negative; whereas, Messrs. Gladstone and Tribe, in their no less admirable little manual, do just the reverse. With them the peroxide plate is negative, and the grey plate positive. Sir David Salomons, if I remember rightly, follows the same usage as Messrs. Ayrton and Perry; but he feels called on, now and then, to interpose an explanation which only adds to the confusion. Referring, for instance, to the "negative plate," he throws in the remark, "That is, the one that is really positive."

No doubt a careful reader can generally gather from the context in each case which plate the writer means to speak of. But all readers are not careful; and even if they were, lucidity of style is still an important quality in scientific writing, and the words used ought, as far as possible, to declare their own meaning. My suggestion would be to call the peroxide plate the *brown* plate, and the other the *grey* plate. These names explain themselves, and do not tend to confuse our ideas of positive and negative: they leave us free to conceive the brown plate as positive in the charge and the grey plate as positive in the discharge, which, I submit, is the true way to conceive them.—Yours faithfully, GERALD MOLLOY.

Catholic University of Ireland, Dec. 19, 1890.

[The difficulty is very similar to that of naming the north and south poles of a magnet. Some teachers try to avoid it by speaking of red and blue poles. The difficulty, like that of the knights and the shield, simply depends on the point of view. We decidedly adhere to the names as well as to the reasons given in our note last week.—ED. *E.*]

### GAS AND ELECTRIC LIGHTING AND VENTILATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the article under this heading (extracted from the *Journal of Gas Lighting*) in your issue of the 19th inst., there appears the following: "Instead of a closed room and a constant quantity of oxygen, any desired supply of the latter may be had from outside. Besides, it is not only a question of the inlet of a current of fresh air for the lights, but this must be done in any case for the human occupants of the room. So that it is only a matter of degree whether oxygen has to be supplied for both purposes or for only one. It is therefore possible to say that the method by which a public hall is lighted cannot make much difference to the fundamental obligation to ventilate it with due regard to the health and comfort of the people who use it."

I think that the fallacy involved in the concluding sentences of the above should not pass unnoticed. It is true "that it is only a matter of degree whether oxygen has to be supplied for both purposes or for only one," but the whole difficulty of ventilating a room efficiently turns upon this question of degree. In order to ventilate a room, a certain interchange must take place between the inner and the outer air. The rate at which this should take place will depend upon the degree of vitiation of the internal air. The difficult problem (so unhappily left unsolved in many cases) is to admit air at such a rate as to effect the necessary interchange without producing draughts. The difficulty increases with the number of persons in the room, and also, but in a greater degree, with the number of gas-jets.—Yours truly, GEO. FLETCHER.

School of Science, Derby, December 22, 1890.

### THE CHEMISTRY OF THE SECONDARY CELL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Allow me to make two very necessary corrections in the "authorised abstract" of the observations I made at the last meeting of the Institution of Electrical Engineers. The formulæ

$$(PbO_2)_{10}\,(H_2O)_5\,PbSO_4 = (H_2Pb_2O_5)_5\,PbSo_4$$

express not "the chemical changes produced by electrolysis," but the composition of a certain sample of lithanode, which I was inclined to regard as a type of the active material in the negative element of a lead secondary battery. The former of the two expressions is the empirical and the latter the theoretical formula. The second correction is that I have not yet obtained a discharge of two amperes per lb. gross weight of cell for two hours. This is what I am *trying* to get, but one and a-half amperes for the two hours is what I have actually obtained.—Yours, &c., DESMOND G. FITZGERALD.

### SELENIUM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: May I be allowed to correct a few inaccuracies in your account of my recent communication to the Physical Society? (See p. 213, *ante.*)

*Paragraph 1 of the Report.*—I began with some remarks on three of the allotropic modifications of selenium. (1) the black amorphous, or vitreous; (2) the red amorphous, a finely divided powder; (3) the crystalline or metallic. Se-

Digitized by Google

lenium in the crystalline form is obtained by keeping amorphous selenium at a temperature of from 100 degrees to 200 degrees for a sufficient length of time, which varies with circumstances, but is generally only a few minutes. Amorphous selenium is a non-conductor. Crystalline selenium conducts, but not well. The specific resistance of a piece which was cast in a glass mould and annealed *out of contact with any metal* was 2,500 megohms.

*Para. 2.*—I showed a simple cell formed by imbedding two short lengths of copper wire in a piece of crystalline selenium, and stated its resistance to be several megohms. I made no reference to Graham Bell's photophone cells. Their resistance was in point of fact only a few hundred ohms, though in respect of sensitiveness to light they were far inferior to my own. *Each* wire of my cells makes twenty turns to the inch, so that the distance between the two electrodes is less than one-fortieth of an inch. *Para. 3.*—I said that the cell should be kept for some time at a temperature a few degrees *below* 217 (which is the melting point of crystalline selenium). After long heating and slow cooling, the resistance of a cell with a surface of 10 sq. cm· is generally about 50,000 ohms.

*Para. 5.*—I did not attribute the fall of the resistance of Prof. Adams's pieces of selenium to the formation of copper selenide, but said that "it would be of great interest to know the cause." Adams's electrodes were invariably formed of platinum wire. (I have discussed the fall of the resistance of Adams's selenium in *Phil. Mag.*, Aug. 1885, pp. 183, 184.)

*Para. 6.*—For "selenide of copper" read "metallic selenide." *Para. 8.*—In the second line, delete the comma after "expected." *Para. 9.*—Here I was completely misunderstood. The following is an extract from my notes, which I have tried to make a little clearer:—"In the discussion which followed the reading of my former Paper, the late Mr. J. W. Clark took exception to a hypothesis therein put forward as to the probable action of the selenides formed in selenium cells [an action which would involve the partial decomposition of the selenides by a current] on the ground that selenide of copper conducted metallically [*i.e.*, without decomposition] and not electrolytically [as I assumed it did]. This he stated to have been proved experimentally by Hittorf. But if the amorphous selenium surrounding the anode in the present case [*i.e.*, in the case of the cell referred to in paras. 7 and 8, and submitted to the meeting] was formed otherwise than by electrolysis, it is difficult to imagine why it should be confined to the anode [as was seen to be the fact] and did not extend also to the kathode and other portions of the cell." The inference, of course, is that J. W. Clark was mistaken, and that copper selenide does conduct electrolytically.

*Para. 10.*—This also may be best amended by an extract. "In the illustration of lectures it is often desirable to be able to exhibit experiments in a striking and attractive manner. The movements of a spot of light upon a scale may be convincing, but they are hardly impressive. Yet the resistance of sensitive selenium cells is so high that the variation [under the influence of light] of currents passing through them cannot easily be demonstrated to an audience in any other manner than by their action upon a reflecting galvanometer. With sufficient battery, however, they may be made to work a delicate relay, and thus to produce indirectly a great variety of startling effects." Some of which were shown.—Yours faithfully,

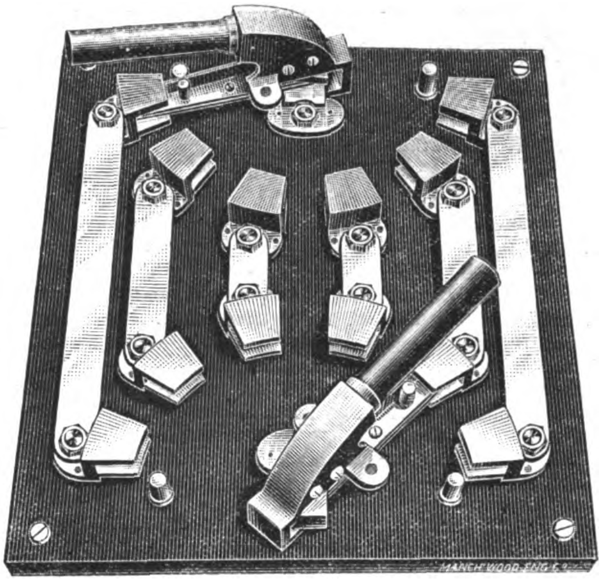
SHELFORD BIDWELL.

Riverstone Lodge, Southfields, S.W.,
December 20, 1890.

## TRADE NOTES AND NOTICES.

THE ARCHER PIPE COMPANY (LIMITED).—We have received from this company a fully illustrated catalogue of their manufactures. The catalogue gives full particulars of the well-known Archer patent lined joint. Instructions how to lay the Archer pipes are given, and a list of the places where the Archer patent jointed stoneware pipes have been put down accompanies the catalogue. Testimonials from users of the pipes are given, including some from electrical firms, a section of the catalogue being devoted to illustrating the suitability of the Archer pipe for electrical purposes.

MESSRS. DORMAN AND SMITH.—The accompanying illustration shows a patent regulator for varying the number of cells in circuit on charging or discharging. This accumulator switch is manufactured by Messrs. Dorman and Smith, of Manchester. The



distance between the jaws connected with the several cells is so arranged as to prevent short circuiting, and a change of circuit from one cell to another is conveniently obtained, regardless of the speed at which the handle is moved.

MESSRS. ENGELBERT AND CO.—We have received from this firm a very useful sheet calendar for 1891 and 1892, copies of which can be obtained on application.

THE DIRECT UNITED STATES CABLE COMPANY.—This company have sent us a neat calendar with space above each day for memoranda.

## PATENT RECORD.

### APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

December 5, 1890.

19,842. W. H. STURGE and J. GRUBB. Birmingham. Improvements in roses for ceilings and wall connectors, for electrical purposes.

19,856. T. J. MURDAY. Newcastle-on-Tyne. A thermo-electric firedamp detector and alarm for use in mines.

19,865. M. A. DAVELUY, Junior. London. Improvements in electric arc lamps.

19,883. L. CAPOCCI, C. PICONE, and A. SPACAGNA. London. Improvements in or relating to self-controlling electrical signals for the prevention of railway accidents.

December 6, 1890.

19,894. S. F. PREST and J. STATTER. London. A new or improved magnetic separator.

19,942. W. P. THOMPSON. Liverpool. Improvements in galvanic batteries, and in the electro-chemical formation of chlorine and chlorine compounds applicable for such batteries and other purpose (F. Marse, Germany).

December 8, 1890.

20,006. C. HUELSER. London. Protective and insulating boxes for subterraneous telegraph conduits (H. Paradies, Germany).

December 9, 1890

20,019. H. W. SABOLD. London. Improvements in circuits for electric railways.

20,043. G. L. ANDERS and C. H. ELLIOT. London. A combination of telephones and mechanical signals.

20,053. P. JENSEN. London. Improvements in and relating to electric signals for engines (H. G. Underwood, United States).

20,062. S. D. WILLIAMS. Newport. An improved perforator for automatic telegraphy.

20,063. S. D. WILLIAMS. Newport. Improved apparatus connected with column printing, telegraphically and otherwise.

Digitized by Google

20,088. L. B. ATKINSON. London. Improvements in the method of driving certain types of percussive rock drills and other tools by electric power.
20,094. M. W. DEWEY. London. Improvements in electric traction increasing system for railways.
20,099. J. E. KINGSBURY. London. Improvements in telephone exchange apparatus (The Western Electric Company, United States).
20,100. P. W. WILLANS. London. Improved means for controlling the supply of electric current to electric mains from a dynamo or dynamos.
20,102. A. S. BAXENDALE. London. An improvement in dynamo-electric and electro-dynamic machines.
20,111. H. H. LAKE. London. Improvements in apparatus for use in the electrolytic decomposition of metallic salts (J. L. Roberts and T. H. McGraw, United States).

December 10, 1890.

20,126. C. E. DUTTON, jun. Washington, United States. Improvement in galvanic batteries.
20,134. W. P. J. FAWCUS and E. W. COWAN. Chester. Improvements in suspending electric light and other cables from a carrying wire.
20,146. G. S. RAM. London. An improved electric lamp.
20,169. A. H. Howard. London. An improved mode of effecting electrical distribution.
20,175. A. FRAGER. London. Improvements in electric meters.
20,204. J. ASHCROFT. Liverpool. Improvements in billiard table electric light and other like reflector shades.

## COMPANIES' MEETINGS & REPORTS.

### Reuter's Telegram Company (Limited).

An extraordinary general meeting of the Company was held at the offices, 24, Old Jewry, on the 23rd inst., when the subjoined resolutions, which were duly passed at a special meeting held on the 6th inst., were submitted for confirmation as special resolutions:—

1. That the capital of the Company be increased to £100,000 by the creation of 2,500 new shares of £8 each, and that the Directors be forthwith authorised, under the provisions of Clause 26 of the Articles of Association of the Company, to issue such shares.

2. That subject to the provisions of the Companies (Memorandum of Association) Act, 1890, the provisions of the Memorandum of Association of the Company, with respect to the objects of the Company, be altered as follows, that is to say, by expunging sub sections 2 and 3 of Clause 3 of the Memorandum of Association, and by inserting in lieu of the sub-sections so expunged the following sections:—

(2.) To carry on and extend the said business, and generally to carry on, acquire, obtain, and supply telegraphic, telephonic, or other news and intelligence, and to issue, publish and circulate, and otherwise utilise, with a view to the profit or advantage of the Company, the same news and intelligence.

(3.) To carry on in the United Kingdom, and in any part of the world, the business of general advertisement contractors and advertising agents in all its branches.

(3a.) To construct, purchase, hire, or otherwise acquire, or work, telegraphs and telephones for any of the purposes hereinbefore mentioned.

Admiral the Right Hon. Sir J. C. Dalrymple Hay, Bart., K.C.B., presided.

The SECRETARY (Mr. Walter F. Bradshaw) read the notice convening the meeting.

On the motion of the CHAIRMAN, seconded by Baron DE REUTER, the resolutions were unanimously confirmed, and the proceedings, which were purely formal, then terminated.

### The Phonopore Syndicate (Limited).

A meeting of this Syndicate was held on Monday, at Winchester House, E.C., Mr. E. H. Pollard presiding.

The CHAIRMAN said the shareholders were aware that the Company was as yet practically a developing Company. They had had many obstacles to encounter, a great many of which had been successfully overcome, while the others were in a fair way of being surmounted. The obstacles were not in any way connected with their patents, or with the value of the invention, but with its development and introduction into general commercial use. This new system had, of course, to some extent, to fight against systems already in use; but the main feature that the Directors had tried to impress on the heads of Government departments, and other departments, and on private individuals was, that the wires at present in use could be used over again for the working of this invention. Thus this invention would give an additional service for the transmission of messages without interfering with the use of the same wires by the telegraph instruments now at work. It was not absolutely necessary, either for the progress of the invention, for the value of the invention, or for their receiving dividends, that they should entirely substitute their instrument for that of the telegraph. It would be quite sufficient to give them a very large income if they could once satisfy the public that it would increase the telegraph transmitting power without the cost of putting up new wires or requiring any special class of operators; a boy who had been operating for a few months with the ordinary telegraph instrument could just as easily work the phonopore. The Chairman concluded by remarking that the great value of the invention had been fully proved to the satisfaction of experts, and it was now only a question of manufacture. He moved the adoption of the report and accounts.

Mr. HENRY KIMBER, M.P., seconded the motion, which was carried unanimously.

The retiring members of the committee, Mr. Kimber and Major-General Shaw Stewart, were re-elected on the motion of the CHAIRMAN, seconded by Mr. DICKSON; and Messrs. Boyce and Ramsay were reappointed the auditors.

Major STEWART moved that Mr. M. I. Brown be elected a member of the committee, and the motion was agreed to after a discussion.

---

The meeting then became special for the consideration of the following resolution:—

"*That the capital of the syndicate be increased by an issue of 10,000 ordinary shares of £1 each, and that the committee be empowered to issue such shares in such manner and on such terms as they may deem best.*"

The CHAIRMAN moved the adoption of this resolution, and said it was a matter of necessity that the Committee should have further funds at its disposal, in order to carry on the manufacture of the instruments and to push the sale. It was proposed, he said, to give the debenture-holders power to turn their debentures into shares within three years, or at an earlier period, if any of the Company's rights were parted with, and this the Directors could not do unless they took the power they now asked. The Directors only took the power to increase the capital in order to comply with the option to convert, if the shareholders decided to give that option. With regard to the Debentures, the Directors had not yet subscribed, because of a rumour that they were going to take them all among themselves; but a considerable number of applications were being held back until the option was sanctioned.

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.

Mr. A. B. ISAAC seconded the motion, which, after a further discussion, was carried *nem. con.*

The proceedings closed with a vote of thanks to the Chairman for his conduct in the chair.

## NEW COMPANIES REGISTERED.

**ALICE-STREET FOUNDRY (LIMITED).**—Registered by Kerr and Lanham, 3, Chichester-rents, Chancery-lane, with a capital of £20,000, in £10 shares. Object: To carry into effect an agreement made between W. S. Llewellyn and Samuel Cartwright, to carry on the business of iron and brass founders, mechanical engineers, &c. The registered office is in Hope-street, Cardiff.

**AVON INDIARUBBER COMPANY (LIMITED).**—Registered by Robinson, Preston and Stow, 35, Lincoln's Inn-fields, with a capital of £50,000, in £5 shares. Object: To acquire the freehold properties and goodwill of the business of indiarubber manufacturers carried on by E. G. W. Browne and J. C. Margetson, in partnership, under the style of the Avon India-rubber Company, at Melksham, Wiltshire.

**ELECTRIC STORES (LIMITED).**—Registered by G. D. Freeman, 103A, Paul-street, Finsbury-square, with a capital of £15,000 in £1 shares. Object: To carry on as principals or agents the business of electrical stores. Registered without Articles of Association.

**JAMES KIDD AND CO. (LIMITED).**—Registered by Rye and Eyre, 16, Golden-square, with a capital of £3,000 in £1 shares. Object: To carry on the business of gas and lighting engineers, fitters, and manufacturers of every kind of apparatus used in connection with lighting.

**LACTITE (LIMITED).**—Registered by Charles Doubble, 14, Serjeants'-inn, Temple, with a capital of £30,000, in £1 shares. Object: To acquire an invention of a new and improved process for the manufacture of a new material designed to serve as a substitute for bone or celluloid.

**PRACTICAL ELECTRO-PLATING AND ENAMELLING COMPANY (LTD.).** Registered by Waterlow and Sons (Limited), London Wall, with a capital of £2,000 in £5 shares. Object: To acquire the above-named business, carried on at Warwick-lane, Coventry. Registered without Articles of Association.

**PURDON-WALTERS' MOTOR SYNDICATE (LIMITED).**—Registered by Wynne and Co., 40, Chancery-lane, with a capital of £10,000 in £10 shares. Object: To acquire, on such terms as the Directors think fit, and to work and vend, any patents and licences under patents.

## CITY NOTES, &c.

**AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).**—The coupons on this Company's Four per Cent. Mortgage Debentures to bearer, due January 1st next, will be paid on and after that date at the Alliance Bank, Bartholomew-lane, London, E.C. Coupons must be left at the Alliance Bank three clear days for examination.

**ALLCHIN, LINNELL, AND COMPANY (LIMITED).**—A petition for the winding-up of this Company of electrical engineers came before Mr. Justice Kekewich on Saturday. Mr. Eve, in support, said that a provisional official liquidator had been appointed, and it was now asked to continue him until the appointment of an official liquidator. The business was a going concern, and the provisional liquidator had had power given to him by the Court to advance or raise £250 at 5 per cent. interest, for the purpose of carrying on current contracts. It was now asked that he might advance a further sum for the purpose, among others, of paying the workmen's wages. The assets of the Company were of great value, consisting chiefly of the goodwill of the business, the fixed machinery, plant, stock, and also current contracts, in respect of which moneys were daily being received. After some discussion the petition was ordered to stand over, and in the meantime the petitioner would have liberty to advance a sum not exceeding £400, on the same terms as before.

**ANGLO-PORTUGUESE TELEPHONE COMPANY (LIMITED)**.—Coupons No. 6 of the First Mortgage and No. 1 of the Second Mortgage Debentures of this Company will be paid, less income-tax, by the Alliance Bank, Bartholomew-lane, on and after the 1st proximo.

**BRAZILIAN SUBMARINE TELEGRAPH COMPANY.**—The receipts of this Company for the week ended December 19th amounted to £6,118. The coupons on this Company's second issue of Five per Cent. Debentures due 31st inst., will be paid on and after that date at the Alliance Bank Bartholomew-lane, London, E.C. Coupons must be left at the Alliance Bank three clear days for examination.

**COWLES SYNDICATE (LIMITED).**—A private meeting of this syndicate was held at Winchester House on Friday last.

**ELECTRICAL AUTOMATIC DELIVERY BOX COMPANY (LIMITED).**—Mr. F. G. Painter (of the firm of Tribe, Clarke, Painter, and Co., of 19, Coleman-street, E.C.), the official liquidator of this Company, will, with the sanction of Mr. Justice Kekewich, forthwith pay 20s. in the £ to all creditors who have proved their claims.

**ELMORE'S FOREIGN AND COLONIAL COPPER DEPOSITING COMPANY (LIMITED).**—The following circular has been issued by the above Company:—"The first annual ordinary general meeting of this Company will be held at the offices of the Company, 64, Cannon-street, London, E.C., on Monday, the 29th day of December, 1890, at 12 o'clock noon, to transact the ordinary business of the Company and, if thought fit, to pass the following resolution:—'*That once at least in every year the Board of Directors shall lay before the Company, in general meeting, a statement of the income and expenditure for the past year, made up to the 31st of December then last past, instead of to the 31st of March as provided in clause 113 of the Company's Articles of Association.*' It is obligatory to hold the above general meeting this year, but, in the event of the foregoing resolution being passed, the second annual ordinary general meeting will be held at the earliest possible date in January next to receive the Directors' report and accounts of the Company, made up to the 31st inst. Notice of the second general meeting, together with a copy of the Company's accounts, will issue in due course. The shareholders will, therefore, understand that it is not important for them to attend the first meeting here on the 29th inst.—By order of the Board, J. SHURMER, Secretary."

**EXCELSIOR COPPER COMPANY (LIMITED).**—At an extraordinary general meeting of the shareholders, held on Friday, Colonel Malleson in the chair, resolutions were passed voluntarily winding up and reconstructing the Company.

**HENLEY'S ELECTRIC LIGHT AND POWER COMPANY (LIMITED).**—A private meeting of this Company was held on Friday at the offices, 27, Martin's-lane, London, E.C.

**HENLEY'S TELEGRAPH WORKS (LIMITED).**—A private meeting of this Company was held on Friday at the offices, 27, Martin's-lane, London, E.C.

**MANITOBA ELECTRIC AND GAS LIGHT COMPANY.**—Messrs. Robert A. McLean and Co. will, on and after January 1st next, pay the half-year's interest, due on that date, on the Six per Cent. First Mortgage Debentures of this Company.

**WEST AFRICAN TELEGRAPH COMPANY.**—The Directors of this Company announce an interim dividend for the first half of the current year of 4s. per share, payable on the 22nd inst.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY.**—The traffic receipts of this Company for the week ending December 19, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,815.

**WHITE'S ASBESTOS COMPANY v. HOARE.**—The hearing of this case, in which the Company sued the defendant for calls, and the defendant, on the other hand, by counterclaim, sought rescission of the contract to take shares, on the ground of misrepresentation in the prospectus, was resumed on Friday before Mr. Justice Day, and resulted in a verdict for the defendant both on the claim and the counterclaim, with costs.

THE NON-CONDUCTOR OF ELECTRICITY.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

MOSSES & MITCHELL, 70, Chiswell-st., London, E.C.

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 659.—Vol. XXVI. FRIDAY, JANUARY 2, 1891. Price Fourpence.

## NOTES.

Our readers will notice that we begin the year by publishing the first of a new series of articles from the pen of Mr. Oliver Heaviside. Although much of Mr. Heaviside's previous contributions to *The Electrician* appealed to a rather limited class of readers, both from the nature of the work and its treatment, we believe that as time goes on it will be found that this work possessed highly valuable and original qualities, and that he was one of the first to appreciate the importance of certain matters which are now being forced very strongly on the attention of those he calls "practicians." In particular, his work on the flow of alternating currents in conductors and sundry questions connected with that complex subject has yet, we think, to receive the appreciation it merits. Dr. Fleming calls attention this week to an important paper of Mr. Heaviside's in the *Philosophical Magazine*, which deserves study by those who are now busy with some difficult and unexpected effects in tubular conductors, since a considerable amount of information concerning these phenomena may be gathered by a careful study of Mr. Heaviside's paper. Mr. Heaviside promises to make the present series of articles, as far as possible, intelligible to readers who do not possess a very copious armoury of mathematical weapons, and we doubt not that a good deal can be accomplished in the cause of truth by a little common algebra *plus* a great deal of common sense.

A simple formula, embodying the results of Ewing's researches on the waste of energy due to hysteresis, is certain of a warm welcome among electrical engineers, as it must prove of great service in the determination of transformer losses. It is this want which Mr. Charles Steinmetz has endeavoured to supply, and we reproduce in this issue the result of his efforts. Starting with the assumption that the loss of energy varies as some power of the density of magnetic lines B, Mr. Steinmetz has found, with the aid of mathematical analysis, that the value of B, raised to the power 1·6, most nearly coincides with the numbers actually obtained from Prof. Ewing's observations. The agreement is so close as to fully justify the original assumption, and although the formula has only been verified with reference to tests made on an iron wire, there seems little reason to doubt its general application. We have taken the liberty of altering some of the symbols employed, as they were already in use with other meanings, and were thus liable to create confusion.

Mr. Steinmetz applies his formula to the case of a transformer, and finds that the watts wasted per cubic inch of iro are given by the formula $1{\cdot}67 \times 10^{-10} \times n\,M^{1{\cdot}6}$, where $n$ is the frequency of the alternate current, and M is the magnetic density in C.-G.-S. lines per square inch. It is unfortunate to have a mixture of three systems of units in a single formula, although it is almost necessary, since the answer to be useful must be expressed in watts, and magnetic densities are generally given in C.-G.-S. measure, as no recognised unit on the "practical" system exists. The word *volt-line* might be used as a provisional name for the practical unit of lines of force. A volt-line is equal to $10^8$ C.-G.-S. lines, and is such that if a wire of length $l$ be moving with a velocity $v$ across the lines of force in a field traversed by $n$ volt-lines per unit area, the voltage induced in the wire is $n\,l\,v$. The above expression for the watts lost per cubic inch becomes $1055\ n\ M^{1{\cdot}6}$, if M is expressed in volt-lines per square inch.

A novel method of investigating the motion of atoms in electric discharges has recently been employed by Mr. John Trowbridge. It depends on what is known as its velocity. It is well known that the note given out by the whistle of a railway engine rises in pitch as well as in amplitude as the train approaches the observer, and falls in pitch as it recedes. A similar effect happens in light when the luminous body is in rapid motion, and the velocity of approach or recession of certain stars has been estimated from the shifting of the lines in its spectrum due to this cause. It occurred to Mr. Trowbridge that if the electric spark consists of a convective discharge accomplished through the agency of swiftly-moving charged atoms, it should be possible to prove it in a similar manner. One of Prof. Rowland's highly dispersive concave gratings was at his disposal, and in consequence he could arrange the apparatus so as to be sensitive enough to detect any such effect if it occurred. The oscillating spark produced by a Leyden jar discharge was passed between two iron terminals, one of which being hollow permitted the axis of the spectroscope to point along the line joining the terminals. The light given out by the approaching atoms would cause a displacement of the lines in one direction, while the receding atoms would yield a dispersion spectrum displaced the other way. No such displacement was detected, the inference being that in spark discharges electrical oscillations do not carry the atoms of metals with them. The electrical waves pass by the atoms, merely causing in them subsidiary heat vibrations.

General Webber, in his letter which appears in our correspondence columns as a reply to the article on "Shaking the Foundations of Science," makes a much better case for the proposed railway than might have been expected, but he altogther fails to convince. It is true that the words of Prince Albert have been partially realised, though a good deal of the space in the "vast quadrangle" is now occupied by a partly-finished building which, whether it is to be public or not, connected with Science and Art or not, or, indeed, useful or not, is somewhat doubtful. "When the Royal Albert Hall was first projected," says General Webber, a pneumatic railway formed part of the original scheme. Practical knowledge of pneumatic railways has not advanced very materially since the date of the Royal Charter of the Commissioners; indeed, they were then considerably more talked about than at present. Physical science, on the other hand, has made great strides, and physical laboratories, which were then practically unheard of, have sprung into existence, and are so important, both scientifically and commercially, that the railway, if it is to inconvenience them, should give way.

Whatever may have been the original objects of the Commissioners of 1851; whatever may have been done in sundry observatories and private laboratories; and, indeed, whatever may have been the wisdom of planting the Central Institution in a locality so widely different from that of the older establishment at Finsbury, we sympathise with the instruction of students, and feel that the good work which is at last being done at South Kensington should not be lightly set aside.

That the permanent galleries of South Kensington are attracting less visitors than formerly is to be regretted, but is there reason to suppose that this is due to want of facilities of access? When were they better than now, if the brief opening of the subway be omitted? Might not a little be done to attract the public? We visited the Science Collection on a recent Bank Holiday morning, with the intention of experimenting *in corpore vili* at the Anthropometrical Laboratory. There was a thick fog, and the gallery was in utter darkness, the anthropometrician was away, and the solitary occupant, a policeman, who emerged from the gloom, informed us in reply to inquiries, that there was neither gas nor electric light, but that the gallery was not closed, and he could not stop us, if we desired to grope among the shadowy cases and their invisible contents.

There is a not uncommon misapprehension as to the legal status of the candle-power of glow lamps. Every one knows that the candle-power of gas is as strictly defined as was possible at the time, by the parliamentary candle which is supposed to burn 120 grains of spermaceti in an hour, with any dodging of the wick that circumstances may dictate. Moreover, it is no secret that medical students and others can earn £100 a year with no very arduous labour, though during somewhat inconvenient hours, by performing the nightly duties of gas inspector. But the *Journal of Gas Lighting*, in common with many other people, appears to think that the supply companies or the Board of Trade, or "somebody," should take care that when we ask for a sixteen-candle lamp we should "see that we get it." In the United States some companies supply light, ours have plenty to do in confining themselves to the supply of electrical energy. Our contemporary is mistaken in supposing that the recently-appointed committee can deal with this matter in any way except indirectly by the establishment of a decent standard of light, and they are in error in supposing that the introduction of cheap inefficient lamps will injuriously affect the profits of the supply companies. It will, indeed, put a stop to contracts at per lamp, but these are happily giving way to the more satisfactory method of charging by meter.

According to the leading electrical journal of Chicago, electrical circles in that progressive city are much agitated by a question which is being discussed at the present moment by the Committee on Electricity of the "World's Columbian Exposition." Is the electrical department to be organised now or next year? The general consensus of outside opinion is that the department should be organised as soon as practicable, that "dilatory tactics" should not be allowed to prevail, and that the process of "prodding" electrical manufacturers at home and abroad should be immediately commenced. This sudden solicitude as to foreign exhibits is somewhat strange in the citizens of a Republic which, as is well-known, is the universe in miniature. The electrical Chicagoans have, however, temporarily abandoned this belief, and now consider that if their "exposition" is to be representative, it must be international; and they are, consequently, exceedingly anxious that the Briton, the Gaul, and the Teuton should, in spite of their "inborn conservatism," be invited without further delay to forget the McKinley Bill and the four thousand miles that separate them from Chicago, and "expose" their electrical decadence to the eyes of progressive Western electricians.

The attitude which will in all probability be adopted by the majority of European electrical firms in regard to the Chicago Exhibition, is that of the gentleman connected with the Allgemeine Elektricitäts Gesellschaft, who, according to the article in our Chicago contemporary, displayed "the most profound and startling indifference to the World's Fair and the electrical department." His company, he said, would make an extensive exhibit at the electrical exhibition at Frankfort-on-the-Main, but, *horribile dictu*, "as for Chicago, he knew nothing about its fair, and he cared less." This, says our contemporary, "was an expression of opinion from a foreigner who had visited the country several times, could speak its language, and, what is still more important, he had quite a large sum of money invested in electrical industries in the United States." Sentiment has but a small place in business affairs, and yet it would be little else than sentiment for a European firm to send its wares several thousand miles across the sea to such an electrically self-sufficient country as the United States of America.

Apart from the question of patents, the telephone seems likely to prove a fruitful source of legal decisions. Some few months ago the validity of contracts made by telephone was

Digitized by Google

called into question in the United States, and the decision arrived at was one eminently characteristic of the legal mind. Contracts by telephone were held to be valid, but as the same rules of evidence were required in telephonic contracts as in contracts made in the ordinary manner, what the law gave with one hand it took away with the other. More recently the right of electric tramways to the use of "earth" has been hotly contested by American telephone companies, and the dispute has given rise to a fine crop of conflicting pronouncements from the bench. The latest point raised is whether registration by telephone is legal? A voter at Macon, Ga., rang up the Town Clerk of that town, and demanded to be registered. The clerk was familiar with the voter's voice, knew that his taxes had been paid; but as the law requires a voter to apply in person, the clerk is said to have his doubts as to legality of the whole proceeding.

**Brussels.**—The municipality has definitely decided not to grant electric lighting concessions, but to undertake the lighting itself.

**Gravesend.**—The opinion of the burgesses of Gravesend has been taken on the electric lighting question, and they have decided in favour of the light.

**A Correction.**—We are informed that the remarks in the authorised abstract of the discussion on Prof. Ayrton's Paper on "The Chemistry of Secondary Cells," attributed to Mr. E. A. Hall, were made by Mr. H. C. Hall.

**The Telegraph in the United States.**—The telegraph system in the West (says Reuter's New York correspondent) has almost completely collapsed owing to the heavy storms and fogs which are prevalent throughout the country.

**Obituary.**—We regret to announce the death, on the 27th ult., of Mr. George Crabtree, who has been in the service of the Eastern Telegraph Company since its formation, and was for some years Superintendent of the Tripoli Station.

**Village Lighting.**—The colliery village of Abercanaid, near Merthyr Tydvil, was lighted for the first time last week by electricity. The same plant supplies current to the Abercanaid Pit, and electrical haulage in the colliery is contemplated.

**The "Electrical Review," New York.**—The London offices of this journal have been removed from Bridge House, 181, Queen Victoria-street, E.C., and all papers and communications should be sent to Mr. Charles Ffrench, the London editor and manager, at the Hotel Victoria, Charing Cross.

**Buckingham.**—We learn that upon the winding-up of the Buckingham Electric Light and Power Company the plant was purchased by Mr. A. C. Rogers, of Prebend House, Buckingham, who is carrying on the lighting. Water power is used, and we understand that the plant is likely to be shortly much increased.

**Society of Arts.**—The following are some of the Papers to be read at the meetings of the Society of Arts, after the Christmas recess:—Prof. William Robinson, "The Use of Petroleum in Prime Motors;" and Mr. H. Newman Lawrence and Dr. Arthur Harries, "Electricity in Relation to the Human Body."

**The School of Electrical Engineering, Hanover-square.**—In connection with the sad death of Mr. Lant Carpenter, to which we refer in another column, we understand that this school will go on, as before, under the management of Mr. Léon Drugman, who, during Mr. Carpenter's illness—that is, since last spring—has been sole manager.

**Interruption of Telegraphic Communication.**—In consequence of a fire at a rag warehouse at Woodbridge (Suffolk), on Monday morning, telegraphic communication between England and India and the Continent was stated to have been interrupted for about six hours. We learn, however, on the best authority, that only four wires out of 50 were damaged.

**Central Station Statistics.**—The Electrical Trades Section of the London Chamber of Commerce have issued the two forms relating to the interchange of statistics which were published in our issue of November 14th. We hope that the scheme will be heartily taken up by the managers of supply companies.

**Weaving by Electricity.**—Herr Lembcke, the Director of the School of Weaving in Crifeld, reports that satisfactory trials have recently been made in the working of silk weavers' looms by electric motors in their own houses. The working of the looms by electrical power from a central station is found to be more satisfactory than the working by means of gas engines.

**St. Thomas' Charterhouse Schools.**—The Clothworkers' Technical Scholarship (value £240) has again been taken by a pupil (aged 13) of these schools. The subjects of examination were mathematics, drawing, science, and the usual English subjects. Recently also 3 out of 4 scholarships offered by the City and Guilds Technical Institute were won by scholars of these schools.

**Bacup.**—At a recent meeting of the Town Council a letter was read from the Board of Trade calling attention to the provisions of section 10, sub-section 1, of the Electric Lighting Order, 1890, and requesting that the Board should be informed what system of electric supply the Corporation proposed to adopt, and stating that it was necessary to obtain the approval of the Board before the work was commenced.

**The London and Paris Telephone Trunk Wire.**—A report having appeared in daily papers that the Government telegraph steamer "Monarch" had arrived at Calais with the telephone cable which is to be laid across the English Channel, and that in the course of the next few days the cable would be laid, we may state that the "Monarch" is at Charlton, and that the cable in question is lying peacefully in Siemens' works.

**Electricity in Railway Shops.**—In the new engineering shops of the Union Pacific Railroad, at Cheyenne, Wyo., one of the most important improvements, says the *Western Electrician*, is a 50-ton electric travelling crane. Five motors are used, one for the crane as a whole, and two for each trolley. The transfer table between the erecting and boiler shops is operated by electricity, and the transfer table for the car shops will also be run in the same manner.

**Postal Telegraph Revenue.**—The receipts from the telegraphic department of the Post-office for the quarter ending December 31, 1890, amount to £615,000, as against £590,000 for the corresponding quarter of 1889, an increase of £25,000 or 4·2 per cent. The receipts for the unexpired portion of the year ending March 31, 1891, amount to £1,840,000, as compared with £1,735,000 for corresponding period of the previous financial year, an increase of £105,000, or 6 per cent.

**The French Elmore Company.**—"In France," says the *Bulletin International de l'Electricité*, "the Société Elmore will be in a somewhat difficult situation, at least at the commencement of its career, owing to the existence of a concern which M. Secretan once knew well, a concern which is in possession of a *clientèle*, and which does not lack means of action. The Société des Métaux, even in the hands of a liquidator, is not an adversary to be neglected, and the Elmore patent is perhaps not the only one possessing the virtues commonly attributed to it."

**The Electric Registration of Meteorological Phenomena.**—The installation of the electrical devices for recording the indications of the meteorological instruments installed at the summit of the Eiffel Tower is now in working order, and on November 25th M. Mascart, says *La Lumière Electrique*, was able to announce to the Académie des Sciences that the velocity of the wind at the top of the Tower that morning was 300 *metres per second*. As this is equivalent to a velocity of about 672 miles per hour, and a pressure of more than one ton per square foot, we think a decimal point must be wanting somewhere.

**The Postal Revenue.**—A Parliamentary return, prepared at the instance of Mr. Shaw-Lefevre, has been issued, giving the

Digitized by Google

gross and net revenue and expenditure of the Post Office for each year for the last 21 years. Every year of the series, with the exception of the years 1872 and 1876, shows, alike in gross and net revenue, a substantial increase over the record of its predecessor. Twenty-one years ago the postal revenue from all sources amounted to £5,074,336, and the expenditure to £3,669,450, leaving a net yield of £1,404,886. In 1889 the revenue reached the total of £9,721,481, and the expenditure had risen to £6,275,085, the net yield being returned at £3,446,396.

**Technical College, Finsbury.**—The autumn courses of Special Lectures at the Technical College have been attended by very large numbers of students. That on Indiarubber, by Mr. T. Bolas, attracted many outside the ranks of ordinary chemical students. The lectures on Electricity Meters, by Prof. Silvanus Thompson, which were concluded in November, are now being revised for publication. Mr. O'Keefe has since been lecturing on Arc Lamps. When the classes re-assemble in January, Prof. Thompson will lecture on Dynamo-machines, on Monday evenings, and on Magnetism on Wednesdays. Prof. Perry continues his lectures on the Applications of the Differential and Integral Calculus to Engineering Topics.

**Gouraud v. Fitzgerald and Others.**—The following letter has been sent us for publication :—

"SIR : As you inform us that passages in the reports prepared by us in the year 1884, in reference to the Consolidated Telephone Company and its associated companies, have given rise to incorrect impressions adverse to yourself, we beg to say that we have since ascertained that, in the hurry of issuing the reports, some inaccuracies occurred in them. In the passages referred to we did not intend to convey that you had been guilty of a breach of duty as a Director of any of the companies mentioned in them, and we regret if any such incorrect impression should have been produced by our reports.—Your obedient servants,

"C. L. W. FITZGERALD,
"A. H. BAKER,
"HENRY GREWING.

"Col. G. E. GOURAUD, Little Menlo, August 6, 1890."

**Institution of Civil Engineers.**—This institution was founded on January 2, 1818, so that it has reached its seventy-third anniversary. Amongst its presidents have been Thomas Telford, Sir John Rennie, James Meadows Rendel, Robert Stephenson, George Parker Bidder, Sir John Hawkshaw, Sir John Fowler, Bart., K.C.M.G. ; Charles Blacker Vignoles, Thomas Hawksley, George Robert Stephenson, John Frederic La Trobe Bateman, Lord Armstrong, C.B. ; Sir Joseph William Bazalgette, C.B. ; Sir Frederick Joseph Bramwell, Bart. ; and Sir George Barclay Bruce. The present president is Sir John Coode, K.C.M.G. The numbers of the various classes now on the books comprise 1,700 members, 2,880 associate members, 427 associates, 19 honorary members, and 927 students—together, 5,953.

**St. Pancras Vestry.**—At the meeting of this Vestry on December 22nd, the Electricity Committee reported that they had inspected the works at the Stanhope-street station, and found the progress in every way satisfactory. With reference to the other works, all of which were being carried out, the engineer had reported that he had tested the boilers of the Babcock and Wilcox Company at Glasgow, and that everything was satisfactory, and the work in a forward state. It was also reported that the engines and dynamos were well advanced. The Electrical Construction Corporation had raised some questions as to the limit of time for their works, and this had been arranged by the engineer, and it was now understood that the station would be ready for them to proceed with their work on April 15th next, and their work was to be completed within two months from that date. In accordance with the terms of the St. Pancras Order, plans of the mains had been deposited with the London County Council and the General Post Office, and one month's notice had been given, as required, to the Gas, Water, and Tramways Companies. The Committee had, therefore, every confidence in informing the Vestry that the whole of the works were progressing satisfactorily.

**Paris.**—Yesterday an important addition was made to the Paris central lighting stations by the coming into operation of the central station of the Edison Company in the Avenue Trudaine. This station, like the others of the same company, is on the three-wire system, and is connected to the station in the Faubourg Montmartre. Its present capacity is 24,000 eight candle-power lamps, but ultimately it will be able to supply twice this number. When complete the plant will comprise six Belleville boilers, and eight Weyher and Richemond engines, coupled direct to eight-pole Edison dynamos, each having an output of 800 amperes and 125 volts at 135 revolutions. The cables are run on porcelain insulators placed in concrete troughs.—The Minister of Commerce has presented a Bill to the Chamber of Deputies, authorising the lighting by electricity of all the Government offices in Paris.—The results of installing letter-boxes on the cars of the Tramways-Sud have proved so satisfactory that the postal authorities extended the system, on New Year's Day, to the cars of the Tramways-Nord. During September, 12,000 telegrams, postcards, and letters were transmitted in this manner from the suburbs to the chief offices in Paris, and in October and November the figures were 15,000 and 17,000 respectively.

**The South Kensington and Paddington Subway Railway.**—The promoters of this scheme, which was withdrawn in the early part of last session, have re-deposited their Bill, with important amendments, in the Private Bill Office of the House of Commons. The first Directors of the proposed Company are the Earl of Kilmorey, Baron Sudeley, the Hon. Edward Spencer Churchill, Sir John Henry Puleston, Mr. John Irving Courtenay, Mr. Samson Fox, Mr. George Newman, Mr. Edward Power, and Major-General Charles Edmund Webber. Power is sought to construct a subway of a little over $1\frac{3}{4}$ miles in length, commencing at a point near the Exhibition-road, Kensington, and terminating in Paddington at the western end of the Bishop's-road bridge over the Great Western Railway. A capital of £276,000 is to be raised, in respect of which the Company will be empowered to borrow an additional sum of £92,000. Power is sought to enter into agreements with the Great Western Railway Company for connecting the subway by junctions with their system at Paddington, whilst several widely permissive clauses are inserted in the Bill, empowering public bodies and the Metropolitan District Railway Company to undertake the construction of this subway alone or jointly, or to subscribe towards the capital of the Company, or guarantee the payment of dividends. The public bodies mentioned are the County Council, the Royal Commissioners of the Exhibition of 1851, the Corporation of the Hall of Arts and Sciences (Albert Hall), the Commissioners of Woods, the Commissioners of Works, and "any vestries or vestry."

**The Influence of the Electric Spark and of the Surrounding Gas on the Rate of the Electric Discharge.**—In a recent number of the *Journal of the Physico-Chemical Society of Russia*, M. P. Bakhmetieff states that he has repeated the experiments of M. Naccari on the loss of charge undergone by an electrified body when close to an electric spark, placing the whole arrangement under a bell-glass and filling it with different gases. Generally speaking the electric spark accelerated the discharge, but charges of positive sign were the more rapidly dissipated in carbonic acid, and in coal gas, while negative electrification disappeared the more rapidly in air, hydrogen, and oxygen. M. Bakhmetieff attributes these results to an unstable molecular allotropic modification of the gases by the electric spark which renders them conducting, but only to electricity of one particular sign. M. A. Nacarri, in the *Atti della R. Accademia delle Scienze di Torino*, Vol. XXV., states, with reference to some further experiments of his, that the influence of the electric spark on the rate of discharge of an electrified body is much diminished by the presence of vapour of water, alcohol, essence of turpentine, ether, and petroleum. He further calls attention to the fact that the presence of a piece of phosphorus near an electrified metal ball causes it to rapidly discharge. This phenomenon is, he says, apparently closely connected with phosphorescence, since it only takes place if the phosphorus emits a glow reaching to the electrified body. The phenomenon ceases in the presence of bodies, like essence of turpentine, which cause phosphorescence to disappear.

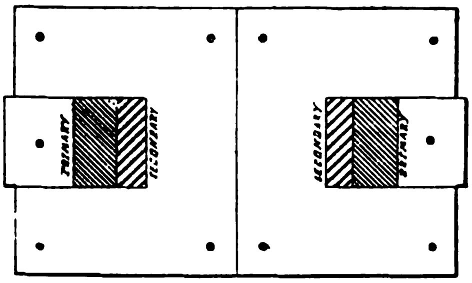
## ELECTRICAL DISTRIBUTION BY TRANSFORMERS FROM CENTRAL AND ECCENTRIC STATIONS.*

BY DR. J. A. FLEMING, M.A.

*(Continued from page 197.)*

Various devices have been invented by Prof. Elihu Thomson for preventing, by any possible chance, the connection of the primary high potential circuit with the secondary. In 1885 he took out a patent for a "Sheath" protective device, in which a copper strip or divided plate connected to the earth is interposed between primary and secondary windings. Another device is to ground one end of the secondary circuit, as described in Prof. Thomson's United States Patent Specification, No. 322,138,

Fig. 10.



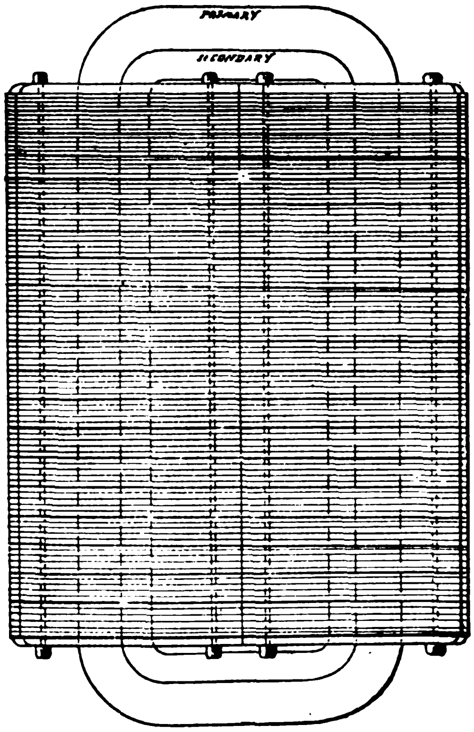


Fig. 12. Fig. 11.

of 1885;† the latest arrangement, however, is the application of the film cut out (described further on in connection with the series socket) to automatically ground the secondary circuit in case the high potential reaches it.

The objection to the film device is that it is apt to be broken down in case of a lightning discharge reaching the line before the lightning arresters have a chance to operate. On underground circuits the film device can be used without any such risk.

Figs. 10, 11, 12, 13, 14 show the various forms of cores which have been used in these transformers. Figs. 10 and 11 showe a type in which the coils are wound about two cores of similar shape, placed back to back, and each built up of C-shaped laminæ. Laminated plugs are driven into the openings over the coils, and the whole securely fastened together with bolts. In this form it will be noticed that the break in the continuity of the iron core is not such as to offer air resistance to the lines of force, its plane being parallel to the plane of those lines.

Fig. 13 shows another form of core in which the coils are wound on formers and then driven over a tongue projecting from a core built of "E"-shaped laminæ. Laminated plugs are driven into the openings over the coils. This is the type of core employed in the type "E" transformer shown in its box in Fig. 8.

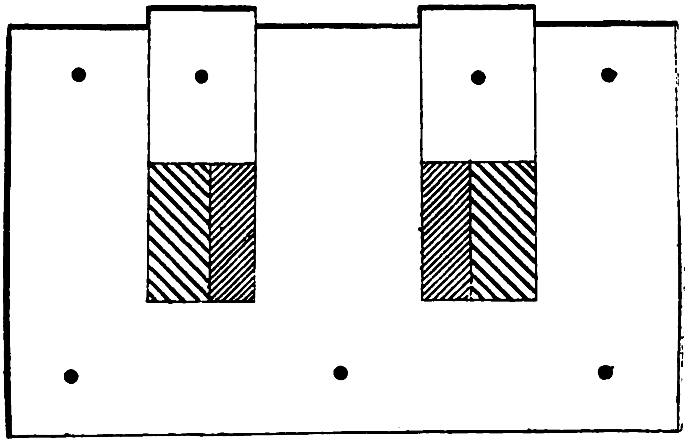

Fig. 13.

Fig. 14 shows the latest form of core. A plug of laminated iron is placed in the centre of a transformer coil, and sheets of iron cut in the form of a hollow rectangle are placed about the coil. These squares fit the plug very closely, and render the magnetic contact very perfect.

No insulating sheets are used between the laminæ of the transformer cores, the oxide of iron formed on the sheets during the annealing process being considered to be sufficient insulation for eddy currents.

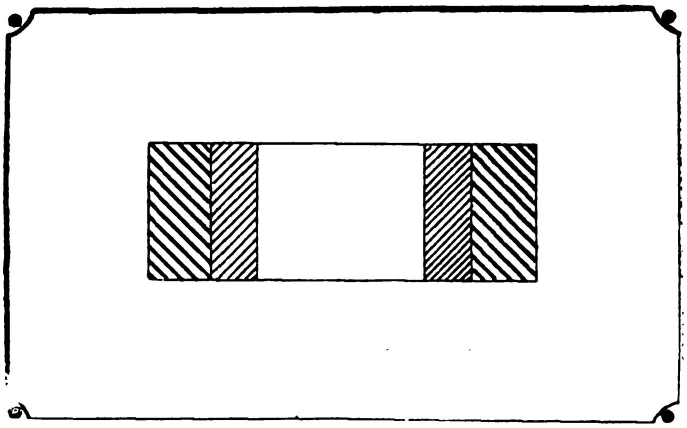

Fig. 14.

A novel device due to Prof. Thomson is employed in the transformers for maintaining the induction of the cores in the plane of the laminæ; zinc sheets, equal in thickness to two or three laminæ are introduced in the core at intervals of five sheets of iron. The magnetic resistance of these sheets prevents any distortion of the lines of induction, and serves materially to increase the efficiency of the apparatus. These sheets are shown by the heavy lines in Fig. 11 of the transformer. The primary and secondary fuses are contained in the ends of the iron cases, access being obtained by lids which can be screwed down. The primary fuses are mounted on ebonite, and the secondary on porcelain bases. It is remarkable to note how short these primary fuses are. The possibility of using such short fuse wires is dependant on the use of a dynamo of high self induction.

* All rights are reserved.

† See letter in *Electrical Review*, Sept. 26, 1885, by J. A. Fleming, and subsequent correspondence.

*Constant-Current Transformer*—Figs. 15 and 16 show two forms of transformer adapted for transforming from a constant potential primary current to a secondary current of constant strength, the potential of the secondary varying with the number of lamps in circuit.

Fig. 15 shows a type in which the coils are wound about opposite ends of a peculiarly-shaped soft iron laminated core. This core is designed so that the magnetism induced by the primary is partially carried through that part of the core enclosed by the secondary circuit, and partly through the air space "A." The transformer core is properly formed and proportioned, so that any decrease in the number of lamps on the secondary circuit by decreasing the secondary circuit resistance

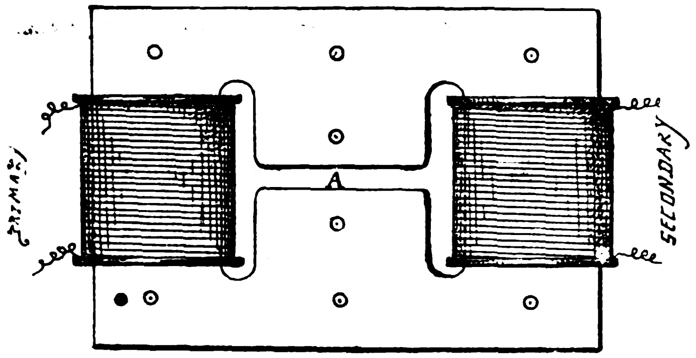

Fig. 15.—Constant-Current Thomson-Houston Transformer.

increases the reaction of the same on the primary, and causes a greater leakage of magnetism across the air space "A." This cuts down the induction in the secondary and increases the self-induction of the primary, thus proportionally decreasing its current.

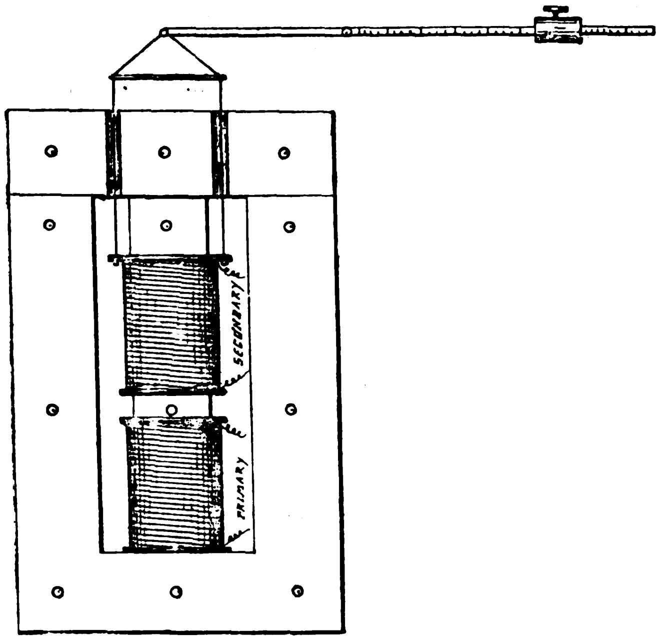

Fig. 16.—Constant-Current Thomson-Houston Transformer.

Fig. 16 shows an ingenious device invented by Prof. Thomson, for maintaining a constant secondary current. It is upon the same principle as the arrangement often used in laboratory experiments, consisting of a secondary coil balanced on a scale arm over a primary coil, the secondary being connected in series with an incandescent lamp. When an alternating current is sent through the induction coil the lamp coil is repelled, and adjusts its height above the primary induction coil, in accordance with the induction in itself,and maintains the current in itself constant even for varying primary current by its changing distance.

The secondary coil of the transformer in question is movbale on the core, and is supported by a rod from a lever bearing an adjustable counter-balance. At full load the counter-balance is so placed as to allow the secondary to lie close to the primary. If the secondary resistance be decreased its current increases momentarily enough to cause the secondary coil to be repelled from the primary and to assume some position above the latter at which point its reaction is the same as before, and its current again becomes normal.

A third device used for the same purpose as the above, but of a different nature, is shown in Fig. 17. A reactive coil, as is shown in Fig. 18, and explained under the head of regulating devices, is connected in the circuit of lamps in series on a constant potential system. Its sheath is counter-balanced by the weight P, and the weak spring S holds the sheath over the coil under normal load. On the extinction of a lamp in the circuit the reaction of the sheath on the coil increases and the

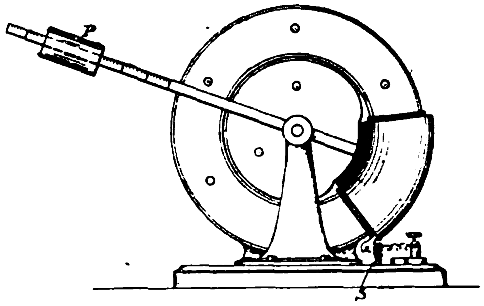

Fig. 17.—Balanced Reactive Coil.

sheath is repelled, thus increasing the self-induction of the coil and reducing the lamp current to its proper amount.

*Regulating Devices.—Reactive Coil or Dimmer.*—This is a device used in alternating current work to serve the same ends as rheostats in direct current plants. They are used in central stations for adjusting the potential of the feeders, and in theatres for controlling the candle power of the lamp.

They are, in principle, choking coils in which the winding is about a laminated soft iron ring, and in which a heavy envelope of copper adjusts, by its position as regards the coil, the self-induction exerted by it.

Fig. 18 shows the general form of the reactive coil. A winding of well insulated copper wire of comparatively few turns surround one part (about one-eighth of the circumference) of a laminated iron ring. Inside the ring is a laminated iron

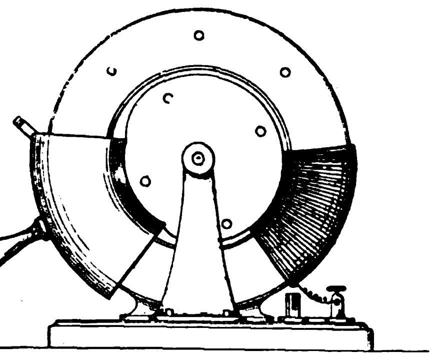

Fig. 18.—Reactive Coil or Dimmer.

drum, supported in bearings and fitting the inside of the ring very closely. A copper sheath is fastened to this drum, and is rotated about with it. When it is over the coil, its width is just sufficient to completely cover it. This sheath mounted upon the drum forms a closed coil, of very large section, about the ring, and fits so closely to it as to leave but a small air space inside or out.

The action of the dimmer will be evident from what has been said of its construction. When the sheath is over the coil, the latter is in the same condition as the primary of a short circuited transformer, and offers but slight resistance to the flow of current. In some dimmers the coil is short-circuited when the sheath is in this position. When the sheath is rotated away

Digitized by Google

from the coil its reactive effect is diminished, and the self-induction of the coil is increased; when it is in its furthest position from the coil the magnetic field of the latter is closed through the drum-shaped core and its self-induction is very great.

This same device, of a movable secondary having but one turn of heavy metal, is used as a transformer for electric welding work. In this case the sheath is not a closed circuit, its terminals being connected to the pieces to be welded.

The principle which underlies this instrument is simply that the presence of a closed secondary circuit near to a primary coil greatly reduces the inductance of that primary, and has the effect of decreasing the impedance of the primary circuit in question. When the sheath is directly over the primary it is traversed by very heavy induced currents, and hence there is a certain waste of energy in employing such an apparatus; but it has great advantages over a simple graded choking coil, in that the impedance can be varied continuously and without breaking circuit.

(*To be continued.*)

## ELECTROMAGNETIC THEORY.—I.

BY OLIVER HEAVISIDE.

§ 1. *Preliminary Remarks.*—The main object of the series of articles of which this is the first, is to continue the work entitled "Electromagnetic Induction and its Propagation," commenced in this journal on January 3, 1885, and continued to the 46th Section in September, 1887, when the great pressure on space and the want of readers appeared to necessitate its abrupt discontinuance. (A straggler, the 47th Section, appeared December 31, 1887.) Perhaps there were other reasons than those mentioned for the discontinuance. We do not dwell in the Palace of Truth. But, as was mentioned to me not long since, "There is a time coming when all things shall be found out." I am not so sanguine myself, believing that the well in which Truth is said to reside is really a bottomless pit.

The particular branch of the subject which I was publishing in the summer of 1887 was the propagation of electro-magnetic waves along wires through the dielectric surrounding them. This is itself a large and many-sided subject. Besides a general treatment, its many-sidedness demands that special cases of interest should receive separate full development. In general, the mathematics required is more or less of the character sometimes termed transcendental. This is a grandiloquent word, suggestive of something beyond human capacity to find out; a word to frighten timid people into believing that it is all speculation, and therefore unsound. I do not know where transcendentality begins. You can find it in arithmetic. But never mind the word. What is of more importance is the fact that the interpretation of transcendental formulæ is sometimes very laborious. Now the real object of true naturalists, in Sir W. Thomson's meaning of the word, when they employ mathematics to assist them, is not to make mathematical exercises (though that may be necessary), but to find out the connections of known phenomena, and by deductive reasoning, to obtain a knowledge of hitherto unknown phenomena. Anything, therefore, that aids this, possesses a value of its own wholly apart from immediate or, indeed, any application of the kind commonly termed practical. There is, however, practicality in theory as well as in practice. The very useful word "practician" has lately come into use. It supplies a want, for it is evident the moment it is mentioned that a practician need not be a practical man; and that, on the other hand, it may happen occasionally that a man who is not a practician may still be quite practical.

§ 2. Now, I was so fortunate as to discover, during the examination of a practical telephonic problem, that in a certain case of propagation along a conducting circuit through a conducting dielectric, the transcendentality of the mathematics automatically vanished, by the distorting effects on an electromagnetic wave, of the resistance of the conductor, and of the conductance of the dielectric, being of opposite natures, so that they neutralised one another, and rendered the circuit non-distortional or distortionless. The mathematics was reduced, in the main, to simple algebra, and the manner of transmission of disturbances could be examined in complete detail in an elementary manner. Nor was this all. The distortionless circuit could be itself employed to enable us to understand the inner meaning of the transcendental cases of propagation, when the distortion caused by the resistance of the circuit makes the mathematics more difficult of interpretation. For instance, by a study of the distortionless circuit we are enabled to see not only that, but also *why*, self-induction is of such great importance in the transmission of rapidly varying disturbances in preserving their individuality and preventing them from being attenuated to nearly nothing before getting from one end of a long circuit to the other; and *why* copper wires are so successful in, and iron wires so prejudicial to effective, long distance telephony. These matters were considered in Sections 40 to 45 (June, July, August, 1887) of the work I have referred to, and Sections 46, 47 contain further developments.

§ 3. But that this matter of the distortionless circuit has, directly, important practical applications, is, from the purely scientific point of view, a mere accidental circumstance. Perhaps a more valuable property of the distortionless circuit is, that it is the Royal Road to electromagnetic waves in general, especially when the transmitting medium is a conductor as well as a dielectric. I have somewhat developed this matter in the *Phil. Mag.*, 1888-9. Fault has been found with these articles that they are hard to read. They were harder, perhaps, to write. The necessity of condensation in a journal where space is so limited and so valuable, dealing with all branches of physical science, is imperative. What *is* an investigator to do, when he can neither find acceptance of matter in a comparatively elementary form by journals of a partly scientific, partly technical type, with many readers, or, in a more learned form, by a purely scientific journal with comparatively few readers, and little space to spare? To get published at all, he must condense greatly, and leave out all explanatory matter that he possibly can. Otherwise, he may be told his papers are more fit for publication in book form, and are therefore declined.

There is a third course, of course, viz., to keep his investigations to himself. But that does not answer, in a general way, though it may do so sometimes. It is like putting away seed in a mummy case, instead of planting it, and letting it take its chance of growing to a useful plant. There is nothing like publication and free criticism for utility. I can see only one good excuse for abstaining from publication when no obstacle presents itself. You may grow your plant yourself, nurse it carefully in a hot-house, and send it into the world full-grown. But it cannot often occur that it is worth the trouble taken. As for the secretiveness of a Cavendish, that is utterly inexcusable; it is a sin. It is possible to imagine the case of a man being silent, either from a want of confidence in himself, or from disappointment at the reception given to, and want of appreciation of, the work he gives to the world; few men have an unbounded power of persistence; but to make valuable discoveries, and to hoard them up as Cavendish did, without any valid reason, seems one of the most criminal acts such a man could be guilty of. This seems strong language, but as Prof. Tait tells us that it is almost criminal not to know several foreign languages, which is a very venial offence in the opinion of others, it seems necessary to employ strong language when the criminality is more evident. (*See*, on this point, the article in *The Electrician*, November 14, 1890. It is both severe and logical.)

§ 4. I had occasion, just lately, to use the word "naturalist." The matter involved here is worthy of parenthetical consideration. Sir W. Thomson does not like "physicist," nor, I think, "scientist" either. It must, however, be noted that the naturalist, as at present generally understood, is a student of living nature only. He has certainly no exclusive right to so excellent a name. On the other hand, the physicist is a student of inanimate nature, in the main, so that he has no exclusive right to the name, either. Both are naturalists. But their work is so different, and their type of mind also so different, that it seems very desirable that their names should be differentiated, and that "naturalist," comprehending both,

Digitized by Google

should be subdivided. Could not one set of men be induced to call themselves organists? We have organic chemistry, and organisms, and organic science; then why not organists? Perhaps, however, organists might not care to be temporarily confounded with those members of society who earn their living by setting a cylinder in rotatory motion. If so, there is another good name, viz., vitalist, for the organist, which would not have any ludicrous association. Then about the other set of men. Are they not essentially students of the properties of matter, and therefore materialists? That "materialist" is the right name is obvious at a glance. Here, however, a certain supposititious evil association of the word might militate against its adoption. But this would be, I think, an unsound objection, for I do not think there is, or ever was, such a thing as a materialist, in the supposed evil sense. Let that notion go, and the valuable word materialist be put to its proper use, and be dignified by association with an honourable body of men.

Buffon, Cuvier, Darwin, were typical vitalists.

Newton, Faraday, Maxwell, were typical materialists.

All were naturalists. For my part I always admired the old-fashioned term "natural philosopher." It was so dignified, and raised up visions of the portraits of Count Rumford, Young, Herschel, Sir H. Davy, &c., usually highly respectable-looking elderly gentlemen, with very large bald heads, and much wrapped up about the throats, sitting in their studies pondering calmly over the secrets of nature revealed to them by their experiments. There are no natural philosophers nowadays. How is it possible to be a natural philosopher when a Salvation Army band is performing outside; joyously, it may be, but not most melodiously? But I would not disparage their work; it may be far more important than his.

§ 5. Returning to electromagnetic waves. Maxwell's inimitable theory of dielectric displacement was for long generally regarded as a speculation. There was, for many years, an almost complete dearth of interest in the unverified parts of Maxwell's theory. Prof. Fitzgerald, of Dublin, was the most prominent of the very few materialists (if I may use the word) who appeared to have a solid faith in the electromagnetic theory of the ether; thinking about it and endeavouring to arrive at an idea of the nature of diverging electromagnetic waves, and how to produce them, and to calculate the loss of energy by radiation. An important step was then made by Poynting, establishing the formula for the flow of energy. Still, however, the theory wanted experimental proof. Three years ago electromagnetic waves were nowhere. Shortly after, they were everywhere. This was due to a very remarkable and unexpected event, no less than the experimental discovery by Hertz, of Karlsruhe, (now of Bonn), of the veritable actuality of electromagnetic waves in the ether. And it never rains but it pours; for whilst Hertz with his resonating circuit was working in Germany (where one would least expect such a discovery to be made, if one judged only by the old German electro-dynamic theories) Lodge was doing in some respects similar work in England, in connection with the theory of lightning conductors. These researches, followed by the numerous others of Fitzgerald and Trouton, J. J. Thomson, &c., have dealt a death-blow to the electrodynamic speculations of the Weber-Clausius type (to mention only the first and one of the last), and have given to Maxwell's theory just what was wanted in its higher parts, more experimental basis. The interest excited has been immense, and the theorist can now write about electromagnetic waves without incurring the reproach that he is working out a mere paper theory. The speedy recognition of Dr. Hertz by the Royal Society is a very unusual testimony to the value of his researches.

At the same time I may remark that to one who had carefully examined the nature of Maxwell's theory, and looked into its consequences, and seen how *rationally* most of the phenomena of electromagnetism were explained by it, and how it furnished the only approximately satisfactory (paper) theory of light known; to such a one Hertz's demonstration came as a matter of course—only it came rather unexpectedly.

§ 6. It is not by any means to be concluded that Maxwell spells Finality. There is no finality. It cannot even be accurately said that the Hertzian waves prove Maxwell's dielectric theory completely. The observations are very rough indeed, when compared with the refined tests in other parts of electrical science. The important thing proved is that electromagnetic waves in the ether at least approximately in accordance with Maxwell's theory are a reality, and that the Faraday-Maxwellian method is the correct one. The other kind of electrodynamic speculation is played out completely. There will be plenty of room for more theoretical speculation, but it must now be of the Maxwellian type, to be really useful.

§ 7. In what is to follow, the consideration of electromagnetic waves will (perhaps) occupy a considerable space. How much depends entirely upon the reception given to the articles. Mathematics is at a discount, it seems. Nevertheless, as the subject is intrinsically a mathematical one, I shall not scruple to employ the appropriate methods when required. The reader whose scientific horizon is bounded entirely by commercial considerations may as well avoid these articles. Speaking without prejudice, matter more to his taste may perhaps be found under the heading TRADE NOTICES. *Sunt quos curriculo.*

I shall, however, endeavour to avoid investigations of a complex character; also, when the methods and terms used are not generally known I shall explain them. Considering the lapse of time since the discontinuance of E.M.I. and its P. it would be absurd to jump into the middle of the subject all at once. It must, therefore, be gradually led up to. I shall, therefore, in the next place make a few remarks upon mathematical investigations in general, a subject upon which there are many popular delusions current, even amongst people who, one would think, should know better.

(*To be continued.*)

## ON THE PROPAGATION OF ALTERNATING CURRENTS THROUGH CONCENTRIC CABLES.

BY DR. J. A. FLEMING, M.A.

Attention having been drawn of late to interesting phenomena in connection with the Ferranti trunk mains, it may be of utility to furnish very briefly the results of some measurements on these cables, reserving further facts for another occasion, and to point out how far these facts fit in with existing theoretical investigations. Particularly also to refer readers of *The Electrician* to some work of Mr. Oliver Heaviside, which will be found to contain a good deal which is pertinent to questions now being discussed. The employment of conductors having quite sensible, even if not very considerable electrostatic capacity in conjunction with alternators and transformers, brings into prominence phenomena which may be broadly called resonance effects, and which need careful study to avoid serious practical mistakes in laying out large systems of electrical distribution. It is convenient to adopt a telephonic nomenclature, and to speak of the alternator or transformer, or both together, placed at the generating end of a trunk main as the Transmitter, and to call the transformer at the distribution end the Receiver.

Let us consider a simple generating and pressure reducing plant consisting of a transmitter, concentric conductor, and receiver. The transmitter and receiver may be considered to be transformers. There are then seven quantities which may be supposed to be given constants. The ohmic resistances of the transmitter, receiver, and conductor; the inductances at given loads of the same three; and the electrostatic capacity of the cable. First, let us consider the cable, supposed to consist of two concentric conductors separated by a tubular dielectric sheath. The capacity C, a length $l$, of such a cable is capable of being calculated from the well-known formula,

$$C = \frac{R\,l}{2 \log_\epsilon \frac{R_3}{R_2}},$$

where $R_2$ is the half-diameter of the outside of the inner conductor, and $R_3$ is the half-diameter of the inside of the outer conductor, and R is the specific inductive capacity of the

dielectric. For the Ferranti mains, the ratio $R_3 : R_2$ is about 2·27, and it appears that the specific inductive capacity of the compressed waxed paper of which the dielectric is formed is nearly 3·5. The experimentally measured capacity of one length of Ferranti cable of about one mile and a-third showed that the capacity of the cable as laid is ·367 of a microfarad per mile.

The self-induction of a concentric cable of this type can be accurately calculated from a formula given by Lord Rayleigh in the *Philosophical Magazine* for May, 1886, and which is given in the form

$$\frac{L}{l} = 2 \log \frac{R_3}{R_2} + \frac{2}{R_2^2 - R_1^2}\left(\frac{R_2^2 - 3R_1^2}{4} + \frac{R_1^4}{R_2^2 - R_1^2} \log \frac{R_2}{R_1}\right)$$
$$+ \frac{2}{R_4^2 - R_3^2}\left(\frac{R_3^2 - 3R_4^2}{4} + \frac{R_4^4}{R_4^2 - R_3^2} \log \frac{R_4}{R_3}\right)$$

in which L is the inductance of a length $l$ of the cable and $R_1$, $R_2$, $R_3$, $R_4$ are the half-diameters of inside of inner, outside of inner, inside of outer, and outside of outer copper conductor. From the carefully measured dimensions of the Ferranti cable I find that

$$L = 1{\cdot}7755\, l.$$

Since one mile = 160931·5 centims., it follows that the self-induction of one mile of the Ferranti cable is ·0002857 henrys The measured ohmic resistance of the copper conductor, taking both inner and outer together, is ·324 legal ohms per mile run of the cable at 0°C.

The frequency $n$ or number of complete periods in the current used has been hitherto 67. If we take $p$ as usual to represent $2\pi n$, we have then

$$n = 67,\ p = 421,\ p^2 = 177220.$$

Let R be the ohmic resistance, C the electrostatic capacity, and L the self-induction of the cable, all per mile run, then,

$$R = {\cdot}324 \text{ ohm.} \qquad R^2 = {\cdot}1049.$$
$$L = {\cdot}000286 \text{ henry.}$$
$$pL = {\cdot}1204. \qquad p^2 L^2 = {\cdot}0145.$$

also $R^2 + p^2 L^2 = {\cdot}1194 = I^2$, and $\sqrt{R^2 + p^2 L^2} = {\cdot}3455$ ohms = I, or the impedance per mile, and I exceeds R by about 7 per cent. Also $C = {\cdot}367$ microfarads $= \frac{367}{10^9}$ farads, and we can calculate from the values above given other important quantities, such as

$$Cp = \frac{1545}{10^7}$$

and
$$P^2 = \sqrt{R^2 + p^2 L^2} - pL = {\cdot}00001738,$$
$$Q^2 = \sqrt{R^2 + p^2 L^2} + pL = {\cdot}00003597\ ;$$

thus
$$P = {\cdot}004 \qquad Q = {\cdot}006,$$

and
$$\frac{P^2 + Q^2}{I^2} = \frac{447}{10^6} \quad (2PR + 2QLp) = {\cdot}00415$$

and
$$(2PLp^2 - 2QpR) = -1{\cdot}216.$$

These numerical quantities are required in calculating the current at the far end of the cable.

Let us first examine the simple case of a condenser of capacity C, of which the terminals are short-circuited by an inductive resistance of inductance $l$ and resistance $r$, and let another inductive resistance L, R connect the terminals of the condenser with a source of simple periodic alternating electromotive force (*see* Fig.) E of frequency $n$.

If $v_1$ and $v$ are the potential differences at any instant of the generator and condenser ends of the line $L_1$ R, and if $V_1$ and V are the maximum values of these potentials, it is not difficult to show that

$$\frac{V_1^2}{V^2} = (A^2 + B^2) + (1 - Cp^2)\frac{R^2 + p^2 L^2}{r^2 + p^2 l^2} + \frac{2Llp^2}{r^2 + p^2 l^2} + \frac{2Rr}{r^2 + p^2 l^2}$$

where $A = 1 - CLp^2$ and $B = CRp$, and $p$, as usual, $= 2\pi n$.

This equation gives us the ratio of the potential differences at the generator and condenser end of the inductive line L, R. Let us examine some particular cases.

(i.) Let $r^2 + p^2 l = \infty$, that is if there is no shunt, then

$$\frac{V_1}{V} = \sqrt{A^2 + B^2} = \sqrt{(1 - CLp^2)^2 + C^2 R^2 p^2}.$$

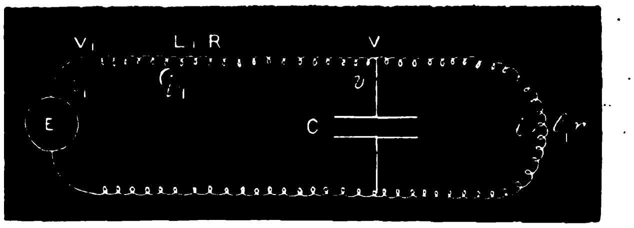
If the values of $C_1$ $L_1$ R and $p$ are such as to make the quantity under the radical less than unity, then V is greater than $V_1$; that is, there is a rise of pressure as we proceed away from the generator end. This reduced case was first treated by Dr. Hopkinson long ago (see *Proc. Institution of Electrical Engineers*, 1884, p. 513. It is easy to see that C, L, R, and $p^2$ may have such values that $V_1$ is greater, equal to or less than V.

(ii.) If $L = 0$, $l = 0$, $r = \infty$;

then
$$\frac{V_1}{V} = \sqrt{C^2 R^2 p^2 + 1}.$$

This case, when there is no inductance and no shunt, is treated by Mr. Blakesley ("Alternating Currents," p. 32, second edition), and since $C^2 R^2 p^2 + 1$ is always greater than unity, $V_1$ in this case is always greater than V; that is, there can be no rise of pressure, but only a fall as we pass from the generator end to the condenser end of the line.

(iii.) Returning to the general case, it is easy to see that whatever be the values of $(1 - CLp^2)$ and $CRp$ it is possible to have such a small value for the impedance $(\sqrt{r^2 + p^2 l^2})$ of the shunt, that V must be less than $V_1$, and hence the pressure less



at the condenser end than at the generator end. This investigation (given only in sketchy outline here) shows fully what takes place when an alternator is connected with a line, ending in such a short-circuited condenser, it indicates that the potential difference of the terminals of the condenser may be very much greater than that of the terminals of the generator. By trying different values of L, C, R, and $p^2$, we can see generally what the result is. We see at once that if $l$ and L are both zero, and $r = \infty$, that V must be less than $V_1$, but that for certain critical values of L, C, R, and $p^2$, we may have V many times greater than $V_1$, as first shown by Dr. Hopkinson.

The general case of a line having capacity, resistance, and self-induction having a transmitting apparatus, having inductance and resistance at one end, and a receiver having the same qualities at the other end, has been very fully and ably treated by Mr. Oliver Heaviside in the *Philosophical Magazine* for 1887 (Vol. XXIII., p. 21, January, 1887). If $L_0$ $R_0$ be the inductance and resistance of the transmitter apparatus, and $L_1$ and $R_1$ that of the receiver, and if L, R, and C be the inductance, resistance, and capacity of the line per unit of length, Mr. Heaviside has given the equation for the amplitude of the current $C_0$ at the receiver end of the line, when a periodic electromotive force of amplitude $V_0$ acts at the transmitter end. The cable having resistance R, inductance L, and capacity C per unit of length, and the transmitter apparatus having inductance $L_0$ and resistance $R_0$, and the receiver apparatus having inductance $L_1$ and resistance $R_1$. The equation for the current amplitude (leaving out of account for the present dielectric conductivity in the cable) is

$$C_0 = V_0 \frac{2\sqrt{Cp}}{(R^2 + p^2 L^2)^{\frac{1}{4}}} \left[G_0 G_1 e^{2Pl} + H_0 H_1 e^{-2Pl} - 2(G_0 G_1 H_0 H_1)^{\frac{1}{2}} \cos(2Ql + 2\theta)\right]^{-\frac{1}{2}}.$$

Digitized by Google

In this equation $p$ stands $2\pi$ times the frequency, or for $2\pi n$, P and Q are given by $P^2 = \left(\frac{pC}{2}\sqrt{R^2+p^2L^2} - Lp\right)$ and $Q^2 = \frac{pc}{2}\sqrt{R^2+p^2L^2} + Lp$, $G_0$, $H_0$ are certain complicated functions of the inductances, resistances, and capacity of the cable and of the transmitter apparatus, and $G_1$, $H_1$ the same for the receiver apparatus, and $\theta$ is likewise a function of all these quantities, whilst $l$ stands for the length of the cable. This equation may be looked upon as a kind of glorified Ohm's law, by means of which the current $C_0$ at the far end of the cable may be calculated from the given constants and the volts $V_0$ at the home end. For further information readers must consult Mr. Heaviside's Paper in the *Phil. Mag.* for January, 1887. Moreover, when we have the value of $C_0$, we have only to take the product of $C_0$ and $\sqrt{R_1^2+p^2L_1^2}$ to get the potential difference of the cable ends at the receiver end, and comparing this with the value of $V_0$ we are able to see if the pressure is greater at the receiver end than at the transmitter end. Not to take up more space, I may say that I have attempted to get the necessary values of all these constants to test this theory in the case of the Ferranti mains. Taking it to be, as I think we may, correct, it is easy to employ it to calculate the rise of pressure at the receiver end in various cases. Thus, suppose a lamp of 10 ohms resistance and negligible inductance is placed at one end of five miles of the Ferranti cable, and an alternator of 10 ohms resistance and negligible inductance at the other end. Let the potential difference at the transmitter end of the cable be $V_0$, required to find the potential difference $V_1$ at the terminals of the lamp at the receiver end. It is not difficult to show that in this case $V_1$ should be *less* than $V_0$ in the ratio of 400 to 583.

If, however, the alternator has a resistance of 10 ohms and an inductance of ·1 henry, and the receiver is a non-inductive resistance of 100 ohms, the cable being the same, then it appears there will be a *rise* in pressure, and that the potential difference at the receiver end will be greater than that at the transmitter end in the ratio of 100 to 70. I hope to treat this matter more fully on another occasion.

## THE RISE OF POTENTIAL DIFFERENCE IN THE DEPTFORD MAINS.

BY W. E. AYRTON.

I am glad to see, from Mr. Glazebrook's article in *The Electrician* for December 26th, that he holds the same view as that given by me to my students some little while ago on this sub-

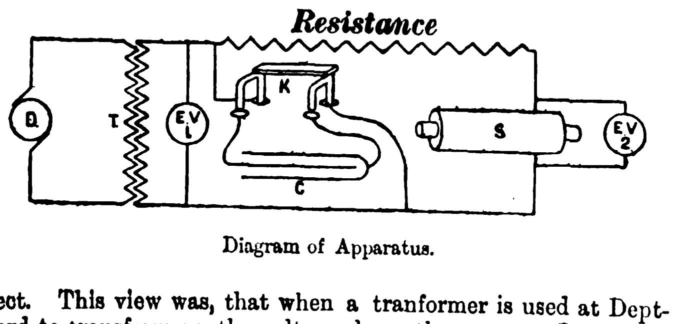


Diagram of Apparatus.

ject. This view was, that when a tranformer is used at Deptford to transform up the volts and another one at London to transform them down, the mere fact that the cable connecting these transformers had capacity was sufficient to cause the potential difference at London to be higher than the potential difference at Deptford. In connection with this suggestion some of the students at the Central Institution made a number of experiments last term under the superintendence of Dr. Sumpner and Mr. Mather. The annexed figure explains the arrangement of apparatus used by them for one set of tests, and with a certain rate of alternation, &c., they found on pressing down the double key, K, by its wooden-cross bar so as to connect the two coatings of the condenser with the two terminals of the secondary coil of the transformer, that while the potential difference measured by voltmeter $E_1V$ (volts at Deptford) went up about 1 per cent., the potential difference measured by the voltmeter $E_2V$ (volts at London) went up over 5 per cent. On raising the key, the potential difference at each end of the circuit went back to its original value, showing that the effect observed in this experiment was solely due to the addition of capacity to the mains.

As the secretaries of the Physical Society tell me that they intend devoting one meeting early this next year *exclusively* to the subject of transformers, I will confine myself on the present occasion to the above brief description of this one experiment.

## ALTERNATE CURRENT CONDENSERS.

BY J. SWINBURNE.

The following explanation of the "Ferranti Effect," due to Mr. Swinburne, formed the latter half of his Paper on "Alternate Current Condensers" recently read before the Physical Society, and a brief abstract of which appeared in our issue of December 19, 1890. As the subject is attracting so much attention, we give this portion of the paper in full.

Loss of power in dielectrics is not confined to condensers; it may be very serious in cables. A condenser that heated excessively was made like the Deptford mains. The dielectric was very much thinner in proportion to the pressure, and allowing the loss per cubic centimetre to vary as the square of the pressure on its sides, a Deptford main would have a loss of, very roughly, 7,000 watts in the dielectric. It does not follow that this is the exact loss in a Deptford main. Very small differences in the constitution of the dielectric cause large variations in the power wasted. The loss may, therefore, be very much greater, or very much less. Taking the specific inductive capacity of the dielectric as 2, a seven mile main has a capacity of 2 microfarads. With 10,000 volts at a frequency of 80, this takes 10 amperes, and 100,000 "apparent" watts; 7,000 watts is only a small percentage of this.

Another unexpected effect has occurred at Deptford. There is an extraordinary rise of pressure. No authoritatively accurate accounts have been published, so it is difficult to say what has happened; but it is said that when the mains are put on the pressure rises. This is generally explained by saying the mains have capacity, and there is self-induction in the circuit, and the capacity and self-induction have a period which corresponds with the frequency of the dynamo, so that the system sympathises, or acts as a sort of electric resonator, thus giving abnormally high pressure. A little consideration will show that this theory is untenable. With such a capacity as that of the Deptford cables the self-induction would have to be enormous.

Let the capacity of the cable be K, and the self-induction of the circuit L, in farads and henrys or quadrants. Call E and C the electromotive force and current respectively. Then,

$$E = L\frac{dC}{dt}$$

and

$$C = -K\frac{dE}{dt}.$$

Combining these equations,

$$\frac{d^2E}{dt^2} = -\frac{E}{KL};$$

so,

$$\frac{dE}{dt}\frac{d^2E}{dt^2} = -\frac{E}{KL}\frac{dE}{dt},$$

and integrating

$$\left(\frac{dE}{dt}\right)^2 = -\frac{1}{KL}(E^2+a)$$

where $a$ is a constant,

or, $$\frac{dE}{dt} = -\frac{1}{\sqrt{KL}} \sqrt{(E^2+a)}.$$

so $$\frac{\sqrt{KL}\,dE}{\sqrt{E^2+a}} = -dt$$

and integrating $$\sqrt{KL} \cos^{-1}\frac{E}{a} = t,$$

therefore, $$E \propto \cos\frac{t}{\sqrt{KL}},$$

and $$T = 2\pi\sqrt{KL}.$$

When a charged condenser is short-circuited through a circuit with self-induction only, oscillation is produced, the current and pressure both varying harmonically with a frequency of $1/2\pi\sqrt{KL}$.

In the Deptford case, with a capacity of two microfarads and a period of 0·0125 the self-induction needed would be half a henry. A choking coil with such a coefficient of self-induction wound to carry 250 amperes, which, I understand, is the load of one main, would take 64,000 volts to get the current through. A transformer only acts on the circuit as a choking coil to the small extent due to the waste induction in it. If built on the lines of commercial transformers this one would have to be large enough to give an output of hundreds of millions of watts to produce a resonator effect. Moreover, a slight alteration in the speed of the dynamo would throw it "out of tune" with the resonator, so that the effect would disappear. For instance, a 5 per cent. variation of speed would alter the pitch of the dynamo nearly a semitone.

It has been stated that there is a difference of apparent ratio in the Deptford transformer when the main is in circuit, that is to say, that though it generally transforms four to one, when the main is on it transforms about 4½ or 5 to one. I would suggest this is impossible. There is always a "drop" in transformers due to waste field. In a transformer for 10,000 volts and 250 amperes if properly designed, it would be well under 1 per cent., probably about one-tenth per cent. In order that an oscillatory current should be confined to the line side by the waste induction which causes a drop of 1 per cent. and 80 periods per second, the frequency would have to be enormous. Such an oscillatory current would also be excluded from the secondary at the London end. Any effect which does not involve enormous frequencies must show on both sides of the tranformers. It might be said that the "drop" of the transformers in the circuit would give enough self-induction to produce a frequency corresponding to an upper partial of the note of the dynamo. If the dynamo E.M.F. does not vary harmonically such an effect might be produced, but it would show on the voltmeters at both ends. To give an increase of 15 or 20 per cent. effective pressure, with a total transformer drop of 1 per cent., the frequency would be, roughly, 1,000, and the effective pressure of the oscillatory component 6,000 volts. This would give 72 amperes, and the "skin effect" would absorb a great deal of power.

There is, however, a simpler explanation. The cables have considerable capacity, and take an appreciable current. This "leads" relatively to the electromotive force, so the capacity current passes in the armature coils when they are just in the position to magnetise the fields more strongly. The fields cannot follow each pulsation of excitation so produced, but are affected by it. Their average excitation is increased. I have tried putting a condenser on one of the old Gramme alternators, which have rather weak fields, and a large number of armature ampere turns. The pressure ran up and burned the voltmeter. I have already gone fully into the action of leading and lagging currents on dynamo fields elsewhere, so the subject need not be pursued here. It would, no doubt, be possible to make an alternator excite itself like a series machine by putting a condenser on the terminals instead of exciting the fields by a direct current machine. Such an arrangement seems scarcely commercial, though interesting.

## NOTE ON THE LAW OF HYSTERESIS.*

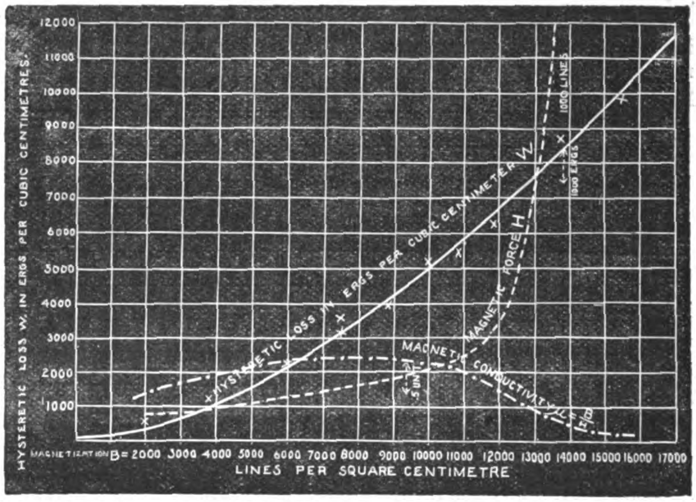
BY CHAS. STEINMETZ.

The magnetism of a magnetic circuit will vary periodically, if subjected to a periodically varying magneto-motive force. The variations of the magnetism, however, will not be simultaneous with the variations of the magneto-motive force, but show a certain lag, so that the curve of magnetism, as a function of the magneto-motive force, forms a kind of loop, the well-known curve of hysteresis.

This phenomenon proves that in the production of the magnetic circuit by the conversion of electric energy into magnetic energy, and in the destruction of the magnetic flow by its reversion into electric energy, a certain amount of energy has been lost, that is, converted into heat.

The amount of energy converted into heat by hysteresis in a full magnetic cycle depends on the maximum magnetisation. It increases with increasing magnetisation, but faster than the magnetisation, so that, when for magnetisation of B = 3,000 (3,000 lines of magnetic force per square centimetre), the loss by hysteresis amounts to 736 absolute units or ergs per cubic centimetre ($10^7$ ergs = 1 watt-second); for four times as high a magnetisation, or B = 12,000, the loss is 6,720, that is, more than nine times as high. On the other hand, the loss increases more slowly than the square of the magnetisation, because the square law would require a loss of 11,776 for B = 12,000.

A great number of experimental researches on the loss of energy due to hysteresis, with different magnetisations, have been made by Ewing; but that law of nature is still unknown, which gives the dependence of the hysteresis upon the magnetisation.



Loss by Hysteresis at Different Degrees of Magnetisation.

In trying to find at least a clue to this law, I subjected a very complete set of Ewing's observations on the hysteric energy, *made on a soft iron wire*, and consisting of 10 tests from a magnetisation of 1,974 lines of magnetic force per square centimetre, up to 15,560 lines per square centimetre, to an analytical treatment by the method of least squares, to ascertain whether the losses due to hysteresis are proportional at all to any power of the magnetisation, and which power this is.

The results of this calculation seem to me interesting enough to publish, in so far as all those observations fit very closely the calculated curve, within the errors of observation, and the exponent of the power was so very nearly 1·6, that I can substitute 1·6 for it, and combine those observations of Ewing in the formula

$$W = \cdot 002\, B^{1\cdot 6},$$

where W is the waste due to hysteresis, in ergs per cubic centimetre ($=10^{-7}$ watt-second) per cycle, and B, the maximum magnetisation (number of lines of magnetic force per square centimetre).

In Table I., in the first column, are given the values of the magnetic force H in absolute units; in the second column is given the maximum magnetisation or induction, B, in lines per square centimetre; in the third column the magnetic conductivity $\mu = \frac{B}{H}$; in the fourth column the hysteretic loss E, in ergs per cubic centimetre, as observed by Ewing, but in the fifth column the hysteretic loss calculated by the formula:

$$W = \cdot 002\, B^{1\cdot 6}.$$

* From the *Electrical Engineer* of New York

Digitized by Google

The sixth column gives the differences of the observed and the calculated values, $E - W$; the seventh column gives these differences in per cents. of $E$.

In the diagram these calculated values, $W$, of hysteretic loss are shown in the curve; the black crosses show the values of hysteretic loss $E$ observed by Ewing.

For comparison there are shown, in dotted lines, the curves of magnetic force $H$ and of magnetic conductivity $\mu = \frac{B}{H}$, as functions of the magnetisation $B$.

It will be seen that the observed values of hysteretic loss are very near the calculated curve through the whole range of observation, and do not show any tendency to deviation, which justifies my considering this coincidence as something more than a mere accident, and, indeed, as an indication of a general law, although certainly this law might be more complicated than the formula.

In Table II, are given the values of hysteretic loss, calculated by the formula:

$$W = \cdot 002\ B^{1 \cdot 6}.$$

To one interesting fact I wish to draw attention: The hysteretic loss seems to be independent of the magnetic force $H$, and only dependent upon the magnetisation $B$; it therefore shows no special singularity at the point of the beginning of magnetic saturation, but increases in the last two observations in Table I., which, for an increase of $B$ by 3,500, require an increase of $H$ by 68, showing high saturation, according to the same rule as in the first eight observations, where $B = 12{,}000$ corresponds to $H = 7$. Therefore the "knee" of the magnetic curve or "characteristic,"

$$B = f(H)$$

is no singular point of the curve of hysteresis $W = \cdot 002\ B^{1 \cdot 6}$, as the diagram shows.

From this formula we get the loss due to hysteresis per cubic inch of soft iron and for the maximum magnetisation of $M$ lines of magnetic induction per square inch, when $n$ = the number of complete periods of the exciting alternate current:

$$W = \tfrac{5}{3} \times 10^{-10}\ n\ M^{1 \cdot 6} \text{ watts.}$$

Table I.

Comparison of Ewing's observed values of $E$, the energy consumed by hysteresis in soft iron, with the values calculated by the equation:—

$$W = \cdot 002\ B^{1 \cdot 6}.$$

| H | B | $\mu$ | E | W | E - W | Difference in percentage. |

## PROVISIONAL ORDERS AND LICENCES GRANTED BY THE BOARD OF TRADE DURING 1890.

### PROVISIONAL ORDERS—Metropolitan.

| Title of Order. | To Whom Granted. | Area covered by Order. |
|---|---|---|
| City of London Electric Lighting (Brush) Order ...... | Brush Electrical Engineering Company, Limited | Portion of the City of London. |
| Crystal Palace and District Electric Lighting Order. | Electric Installation and Maintenance Company, Limited | Portions of following Districts, viz., Parishes of Lambeth and Camberwell, District of Lewisham District Board of Works, and of Beckenham Local Board. |
| Lambeth Electric Supply Order ........................... | House-to-House Electric Light Supply Company, Limited | Portion of the Parish of St. Mary, Lambeth. |
| North London Electric Supply Order ...................... | Ditto | The Parish of Islington. |
| Wandsworth District Electric Supply Order ........... | Ditto | The District of the Wandsworth District Board of Works. |
| City of London (East District) Electric Lighting Order | Laing, Wharton and Down Construction Syndicate, Limited | Portion of the City of London. |
| London Electric Supply Corporation Electric Lighting (Metropolitan) Order | London Electric Supply Corporation, Limited | The Parish of St. George the Martyr, Southwark and a portion of the Parish of Camberwell. |
| Metropolitan Electric Supply Company (Paddington) Lighting Order. | Metropolitan Electric Supply Company, Limited | The Parish of Paddington. |
| St. James' Electric Lighting Order ....................... | St. James' and Pall Mall Electric Light Company, Limited | The Parish of St. James', Westminster. |

Provisional Orders (Provincial) is given on next page.

### LICENCES—Provincial.

| Title of Licence. | To Whom Granted. | Area covered by Licence. |
|---|---|---|
| Bath Electric Lighting Licence ........................ | Mr. H. G. Massingham ................. | Portion of the City of Bath. |
| Chelmsford Electric Lighting Licence.................. | Messrs. Crompton and Co., Limited ... | Municipal Borough of Chelmsford. |
| Dublin Electric Lighting Licence (Private)............ | Corporation of Dublin .................... | City of Dublin. |
| Newcastle and District Electric Lighting Company's Licence | Newcastle and District Electric Lighting Company, Limited | City of Newcastle. |
| Newcastle-upon-Tyne Electric Supply Company's Licence | Newcastle-upon-Tyne Electric Supply Company, Limited | City of Newcastle. |
| Northampton Electric Lighting Licence (Provisional Order subsequently granted, when powers under Licence ceased) | Northampton Electric Light and Power Company, Limited | Municipal Borough of Northampton and portions of the Rural Sanitary Districts of the Northampton and Hardingstone Unions. |
| Southampton Electric Lighting Licence .................. | Southampton Electric Light and Power Company, Limited | Municipal Borough of Southampton. |

Provisional Orders.—Provinces.

| Title of Order. | To Whom Granted. | Area covered by Order. |
|---|---|---|
| Aberdeen Electric Lighting Order | The Town Council of Aberdeen | The City and Royal Burgh of Aberdeen. |
| Accrington Electric Lighting Order | The Corporation of Accrington | The Municipal Borough of Accrington. |
| Ashton-under-Lyne Electric Light and Power Order | Municipal Electric Light and Power Corporation (Limited) | The Municipal Borough of Ashton-under-Lyne. |
| Ayr Burgh Electric Lighting Order | The Town Council of Ayr | The Municipal Burgh of Ayr. |
| Bacup Electric Lighting Order | The Corporation of Bacup | The Municipal Borough of Bacup. |
| Barnsley Electric Lighting Order | The Corporation of Barnsley | The Municipal Borough of Barnsley. |
| Bedford Electric Lighting Order | The Corporation of Bedford | The Municipal Borough of Bedford. |
| Belfast Electric Lighting Order | The Corporation of Belfast | The City of Belfast. |
| Birkenhead Electric Lighting Order | The Corporation of Birkenhead | The Borough of Birkenhead. |
| Blackburn Electric Lighting Order | The Corporation of Blackburn | The Municipal Borough of Blackburn. |
| Blackpool Electric Lighting Order | The Corporation of Blackpool | The Municipal Borough of Blackpool. |
| Bognor Electric Lighting Order | The Electric Trust (Limited) | The Local Board District of Bognor. |
| Bournemouth Electric Supply (Brush) Order | Brush Electrical Engineering Company (Limited) | The District of the Bournemouth Improvement Commissioners, and a portion of the District of the Poole Urban Sanitary Authority. |
| Bournemouth Electric Supply (House to House) Order | South of England House-to-House Electricity Company (Limited) | The Urban Sanitary District of Bournemouth. |
| Burnley Electric Lighting Order | The Corporation of Burnley | The Municipal Borough of Burnley. |
| Burton-upon-Trent Electric Lighting Order | The Corporation of Burton-upon-Trent | The Municipal Borough of Burton-upon-Trent. |
| Bury Electric Lighting Order | The Corporation of Bury | The Municipal Borough of Bury. |
| Cambridge Electric Lighting Order | The Corporation of Cambridge | The Borough of Cambridge. |
| Chatham, Rochester, and District Electric Lighting Order | Chatham, Rochester, and District Electric Lighting Company (Limited) | Portions of the Urban Sanitary Districts of the City of Rochester, Chatham Extra, and Gillingham. |
| Cheltenham Electric Lighting Order | The Corporation of Cheltenham | A portion of the Municipal Borough of Cheltenham. |
| Chester Electric Lighting Order | The Corporation of Chester | The Urban Sanitary District of the City of Chester. |
| Coatbridge Electric Supply Order | Scottish House-to-House Electricity Company (Limited) | The Burgh of Coatbridge. |
| Darlington Electric Lighting Order | The Corporation of Darlington | A portion of the Municipal Borough of Darlington. |
| Derby Corporation Electric Lighting Order | The Corporation of Derby | The Municipal Borough of Derby. |
| Dover Electric Lighting Order | The Corporation of Dover | The Borough of Dover. |
| Dundee Electric Lighting Order | The Gas Commissioners of Dundee | Portion of the Parliamentary Burgh of Dundee. |
| Eastbourne Electric Supply Order | Eastbourne Electric Light Company (Limited) | The Municipal Borough of Eastbourne. |
| Fleetwood Electric Lighting Order | The Fleetwood Improvement Commissioners | The Urban Sanitary District of Fleetwood. |
| Galway Electric Lighting Order | Galway Electric Company | The District over which the Galway Town Improvement Commissioners are the Urban Sanitary Authority. |
| Glasgow Corporation Electric Lighting Order | The Town Council of Glasgow | The City and Royal Burgh of Glasgow. |
| Great Yarmouth Electric Lighting Order | The Corporation of Great Yarmouth | The Borough of Great Yarmouth. |
| Hastings and St. Leonards-on-Sea Electric Supply Order | Hastings and St. Leonards-on-Sea Electric Light Company (Limited) | The Borough of Hastings. |
| Hastings (Public Purposes) Electric Lighting Order | The Corporation of Hastings | The Borough of Hastings. |
| Hove Electric Lighting Order | The Hove Commissioners | The Town and District of Hove. |
| Huddersfield Electric Lighting Order | The Corporation of Huddersfield | The County and Municipal Borough of Huddersfield. |
| Kelvinside Electric Lighting Order | Kelvinside Electricity Company (Limited) | The District of Kelvinside. |
| Kingston-upon-Hull Electric Lighting Order | The Corporation of Kingston-upon-Hull | The County Borough of Kingston-upon-Hull. |
| Lancaster Electric Lighting Order | The Corporation of Lancaster | The Municipal Borough of Lancaster. |
| Leicester Electric Lighting Order | The Corporation of Leicester | The Municipal County Borough of Leicester. |
| Malvern Electric Lighting Order | The Local Board of Malvern | The Local Government District of Malvern. |
| Manchester Electric Lighting Order | The Corporation of Manchester | Portion of the City of Manchester. |
| Morecambe Electric Light and Power Order | Messrs. T. R. Andrews and T. Preece | The District of the Morecambe Local Board. |
| Moss Side and Stretford Electric Lighting Order | Manchester House-to-House Electricity Company (Limited) | The Local Board Districts of Moss Side and Stretford. |
| Northampton Electric Lighting Order | Northampton Electric Light and Power Company (Limited) | The Municipal Borough of Northampton, and portions of the Rural Sanitary Districts of the Northampton and Hardingstone Unions. |
| Nottingham Electric Lighting Order | The Corporation of Nottingham | The Borough of Nottingham. |
| Oldham Electric Lighting Order | The Corporation of Oldham | The Borough of Oldham. |
| Oxford Electric Lighting Order | Electric Installation and Maintenance Company (Limited) | The Urban Sanitary District of Oxford. |
| Plymouth Electric Lighting Order | Devon and Cornwall Electricity Supply Company (Limited) | The County Borough of Plymouth. |
| Portsmouth Electric Lighting Order | The Corporation of Portsmouth | The Municipal Borough of Portsmouth. |
| Preston Electric Lighting Order | National Electric Supply Company (Limited) | A Portion of the Borough of Preston. |
| Preston and Fulwood Electric Lighting Order | Lancashire and Cheshire House-to-House Electricity Company (Limited) | The County Borough of Preston and the District of the Fulwood Local Board. |
| Salford Electric Lighting Order | The Corporation of Salford | The Municipal County Borough of Salford. |
| Sevenoaks Electric Lighting Order | The Electric Trust (Limited) | The Local Board District of Sevenoaks. |
| Stafford Electric Lighting Order | The Corporation of Stafford | The Municipal Borough of Stafford. |
| Stockton-on-Tees Electric Lighting Order | The Corporation of Stockton-on-Tees | The Municipal Borough of Stockton-on-Tees. |
| Tiverton Electric Lighting Order | The Corporation of Tiverton | A portion of the Municipal Borough of Tiverton. |
| Tunstall Electric Lighting Order | The Electric Trust (Limited) | The Local Board District of Tunstall. |
| Walsall Electric Lighting Order | The Corporation of Walsall | The Borough of Walsall. |
| Wigan Electric Lighting Order | The Corporation of Wigan | The Borough of Wigan. |
| Windsor Electric Supply Order | Windsor and Eton Electric Light Company (Limited) | The District of the New Windsor Urban Sanitary Authority and a portion of the District of the Eton Rural Sanitary Authority. |
| Woking Electric Supply Company Order | Woking Electric Supply Company (Limited) | The Parish of Woking. |
| Wolverhampton Electric Lighting Order | The Corporation of Wolverhampton | The Municipal Borough of Wolverhampton. |
| Worcester Electric Lighting Order | The Corporation of Worcester | The City of Worcester. |
| Wrexham Electric Light and Power Order | Wrexham and District Electric Supply Company (Limited) | The Municipal Borough of Wrexham. |
| York Electric Lighting Order | The Corporation of York | The City of York. |

# The Electrician.

**Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.**
**Editorial, Publishing, and Printing Offices:**
**SALISBURY COURT, FLEET ST., LONDON, E.C.**
*Telephone No.* 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

*All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher,* "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*" *All other letters to be addressed to the Editor.*
*All letters intended for insertion in* "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*
"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*
*New Volumes of* "THE ELECTRICIAN" *commence in May and November.*

SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

| | 3 months. s. d. | 6 months. s. d. | 12 months. s. d. |
|---|---|---|---|
| For the United Kingdom | 5 0 | 10 0 | 19 6 |
| For Foreign Parts and Colonies:— | | | |
| Within Postal Union | 6 6 | 12 6 | 24 0 |
| Aden Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar | 7 6 | 14 6 | 28 0 |

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.*
**It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**
*Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.*
TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday evening.*
SMALL PREPAID ADVERTISEMENTS *(for Rates see page xvii.) are accepted up to 4 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

**"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.** (Royal 8vo.)

*Early in each year is issued* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consisted of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*
*The 1891 Edition is now actively preparing, and Subscription and Advertisement Orders, New Names, Corrections, &c., can be received.*

ELECTRICAL BOOKS AND PUBLICATIONS.

*All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of* "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

# 1890.

Though not marked by any occurrences of startling novelty, the year 1890 has been an interesting and, from some points of view, an eventful one. The devotees of pure science will remember it as the year in which EWING enunciated his molecular theory of induced magnetism, and the Royal Society elected Sir WILLIAM THOMSON as its President. To the practical man the past twelve months will be memorable, inasmuch as they have witnessed the realisation of FERRANTI's bold conception of supplying central London with current generated at Deptford, the establishment on a firm basis, in the heart of the Metropolis, of a widespread system of electric supply, and the opening of the City and South London Railway. Even the telephone engineer and the electrical litigant will have cause to remember 1890; the one by reason of the expiry a few weeks ago of the Bell patent, and the various signs that seem to portend a period of sharp competition for the leading telephone company of the United Kingdom; the other, by reason of the final invalidation of the Gaulard-Gibbs transformer patent, and the second pronouncement in the Scotch courts to the effect that there was nothing in BRUSH's so-called compound-winding patent No. 2,003 of 1878 which was not to be found in VARLEY's patent No. 4,905 of 1876.

In the Metropolis the past year has been one of steady progress. Mains have been laid, central stations taken over from the contractors, and customers connected up. Twelve months ago there were thirteen central lighting stations in

Digitized by Google

the Metropolis supplying electricity under statutory powers, to-day there are seventeen; and the laying of mains and the connecting up of customers has been carried out with such an amount of vigour that when the year closed nearly 120 miles of conductors had been buried beneath the streets of London, and some 200,000 lamps were dependent upon public companies for their current. It was not to be expected that so much would be achieved without rebuffs, but fortunately for the other supply companies the demon of mischief seems to have been attracted by Mr. FERRANTI'S engineering audacity, and the numerous mishaps inevitable in every novel enterprise have in consequence been focussed upon the London Electric Supply Corporation's system. First of all, the ratio of transformation of the transformers at the Grosvenor Gallery sub-station was found to be distorted, and 8,500 volts at Deptford apparently became 10,000 in London. The large electrostatic capacity of the Ferranti mains, and the inductance of the "step-up" transformer at Deptford were "reasonably suspected," and the phenomenon was no sooner made public than explanations of it were forthcoming, some of which are appearing in these columns. The next phenomenon was a disaster, namely, the burning out of the Grosvenor Gallery transformer sub-station on November 15th, and this was followed on December 3rd by the complete breakdown of the bank of hastily-repaired converters. The London Company then wisely determined to shut down until everything, both at Deptford and in Bond-street, was in thorough order, and it is to be hoped that when the supply is recommenced this company's system will not again be the target for "the slings and arrows of outrageous fortune." In the Provinces, apart from municipal enterprise, there has been comparatively little electric lighting work. At Newcastle the two supply companies have prospered, and Fareham, Lynmouth, Weybridge, and Woking have been added to the list of towns in which central stations are in operation.

Encouraged by the Board of Trade, and, in most instances, by the ratepayers, local authorities have been peculiarly active during the past year in the matters of electric lighting. In August, 43 Provisional Orders out of a total of 74 were granted to municipalities; towns as diverse as Birkenhead and Cheltenham, Dover and Glasgow, Portsmouth and York being equally eager to dabble in municipal lighting. Moreover, the tide shows no signs of slackening, since only ten days ago out of 70 memorials deposited at the Board of Trade, no less than 37 emanated from local authorities. The question of interest to electrical engineers is what the local authorities propose to do with the Orders they obtain, and so far, it must be confessed, the future is not very clear. In some towns absolutely no steps have been taken to carry out statutory obligations, in others the report stage is within sight, in others the stage of visiting the central lighting stations of the Metropolis has been reached, while in two cases, those of Brighton and St. Pancras, whose Orders date from 1883, money has been voted, a foundation-stone has been laid, and a well-considered scheme is in process of execution. Corporations are, however, notoriously slow-moving bodies, but the Board of Trade is evidently determined, if we may judge by its recent polite inquiries at Dundee, Bacup, and elsewhere, that Orders shall not, for one thing, be used by local authorities merely for purposes of obstruction. While some municipal authorities have elected to secure electric lighting powers and to do nothing, others have preferred the reverse process. Since the beginning of 1890 the streets of Bath, Chelmsford, and Fareham have been lighted by electricity, and similar contracts have been entered into by the Corporation of the City of London and by Swansea.

From the point of view of increase in mileage, electric traction cannot be said to have witnessed any important development in the United Kingdom during the year which has just elapsed. If, however, we look somewhat more closely into the matter, we find that distinct advances have been made. The Central London Railway Bill, although ultimately rejected by the Upper House, served a purpose. It drew attention to the marvellous progress of electric traction across the Atlantic, and it gave the public an idea of the many advantages attendant on the use of electricity as a motive power. But in the opening on December 18th of the City and South London Railway a still more tangible step forward was taken. In a few months' time, when the minor defects which at present militate in some degree against the success of this line have disappeared, the Select Committees, who will then once more be considering the Central London Railway Bill, will have an opportunity of seeing for themselves that electric traction is an actuality and not some "wild cat" idea from across the ocean. With prejudices and doubts once removed, electric traction may be trusted to rapidly make its way. Mention must also be made of the steady service which has been maintained during the past year by the accumulator cars on the Barking-road line, and of the fact that the West Metropolitan Tramway Company has at last extorted the permission of the Hammersmith Vestry to lay down between Uxbridge-road and Kew a line on Mr. LINEFF'S ingenious closed-conduit system. Across the Atlantic electric traction continues to gain ground in spite of the strenuous opposition of the telephone companies, and in many instances also of the town authorities, to the single-trolley system.

The lapse on December 9th of the Bell patent, and the approaching expiration of the important transmitter patent has given rise to considerable agitation in the usually quiet telephonic world. The National Telephone Company, threatened with competition, has announced a wholesale reduction of rentals in the provinces, and in London it has promised complete metallic circuits. The National Company has also continued to strengthen its position by trunk wire extensions, and on October 19th the line connecting London with the North was at last opened to the public. As to whether or not the Post Office intends to depart from its attitude of "armed neutrality" it is difficult to say, but there can be no doubt that it might without entering into direct competition with the National Company render considerable service to the public by making use of the telephone as a feeder to its magnificent system of telegraphs. In submarine cable circles the chief events of note have been the International Telegraph Conference, which was held at Paris in May, one of the principal results being the adoption of an authorised vocabulary for code messages on the European régime, and the question of the reduction from 9s. 4d. to 4s. per word of the Australasian tariff under a guarantee by some of the Australasian Colonies to the cable companies concerned of half the loss involved. It is expected that the negotiations will be speedily concluded, and the new rates brought into operation at an early date. A few new cables, such as the Halifax-Bermuda and that along the West Coast of South America, have been laid, but as a rule the companies have been content with multiplying existing lines, the principal instance being that of the Eastern Telegraph Company's quadruplicate Red Sea cable.

Although eventful in other respects, the year 1890 cannot be said to have produced many new types of heavy electrical engineering machinery, the most novel development being, perhaps, the Westinghouse arc-light alternator. It may, therefore, be considered that the art of dynamo making has

Digitized by Google

attained a very satisfactory stage of completeness. Inventive stagnation does not mean commercial stagnation, and the balance-sheets of manufacturing companies and the reports which other firms have sent us have shown that the electrical trade has been very active. One new company naïvely informs us, indeed, that it "has been engaged in the arduous task of establishing a reputation;" but there are many who will this year be gratified in a more substantial manner by good solid profit on the hard work that has been done during the past twelvemonth. However, the elder branches of heavy electrical engineering may slacken in their development of novelties, electric welding, electric tanning, electric bleaching, and the electrical purification of sewage, are evidences that the entire field is not yet exhausted. Electric welding, while coming into extensive use in the United States, does not make much headway with us; on the other hand, tanning by electricity has so far advanced in this country as to occupy a place in the law list, an unmistakable sign of commercial vitality. Electric bleaching continues to make steady progress, both in Europe and America, and the possibilities of purifying sewage on a large scale by means of electricity will soon be settled one way or the other by the report which will shortly be made on the subject to the Corporation of Salford.

Papers read before the Institution of Electrical Engineers are not for the most part of a very startling character, but have a flavour of hard work and practical experience, and the papers read during the past twelve months have not proved exceptions to this rule. Following Dr. Hopkinson's Presidential Address on "Magnetism," we had a paper from Mr. Swinburne on "The Theory of Armature Reactions in Dynamos and Motors," and another covering much the same ground, though in a very different style, by Mr. Esson, on "Some Points in Dynamo and Motor Design," which was deservedly awarded the Institution premium. These two able papers brought out for the first time the points of difficulty which crop up in the construction of large central station dynamos, and they gave rise to an interesting and at times animated discussion extending over several evenings. In April Dr. Lodge, nothing daunted by Mr. Preece's assertion that the lightning protectors at present in use were the acme of cheapness and reliability, and that consequently there was no need for a new one, read a paper on an ingenious form of lightning guard which he had devised. At the Edinburgh meeting of the Institution Prof. Ayrton read a valuable paper on "The Working Efficiency of Secondary Cells," and followed it up in November by another on "The Chemistry of Secondary Cells." These two papers resulted in a long and practical discussion, extending over three evenings. At the meeting of the British Association in Leeds the papers of interest were of the pure science order. Mr. R. T. Glazebrook read a paper before Section A, in which he tabulated the various determinations of the ohm, and described the different methods which had been employed, and concluded by stating that in his opinion the resistance of a column of mercury of 1 sq. mm. section and 106·3 cms. long was the nearest approximation to the true ohm. This value was ultimately adopted by the Electrical Standards Committee of the British Association, and will probably shortly be legalised by Act of Parliament. A most brilliant paper was communicated to the meeting by Prof. J. A. Ewing, in connection with his molecular theory of induced magnetism. The mutual action of a group of magnetised needles has often been examined, but it was left to Prof. Ewing to see in it the representation of the intermolecular forces at work in a bar of iron. He has thus been able to coherently explain the general characteristics of the process of magnetisation, and has advanced the theory of magnetism in a most marked manner.

The year 1890 has, therefore, been fruitful both in brilliant theoretical speculation and in solid practical progress, and we have every reason to hope that when, twelve months hence, the time again comes round for taking a retrospective glance, the record will be equally encouraging.

## OBITUARY.

### WILLIAM LANT CARPENTER.

We regret to have to record the sad death, at his residence at Harlesden, on the morning of Tuesday, December 23rd, of Mr. William Lant Carpenter, one of the managers of the School of Electrical Engineering, Princes-street, Hanover-square. Mr. Carpenter had been in failing health for some time past, but recently had become so much better that it was hoped he would be able to return to his work in the spring.

Mr. Carpenter was born in 1841, and was the eldest son of the late Dr. W. B. Carpenter, C.B., F.R.S. He was educated at University College School—where he held a scholarship for five years, and gained numerous prizes—and at University College. He took Bachelor's degrees in Arts and in Science, with honours, in the University of London in 1860 and 1861. For several years in early manhood he resided in Bristol, as one of the partners in a large manufacturing business, involving a considerable knowledge of industrial chemistry and physics. During this period he was one of most active promoters of the movement that led to the foundation of University College, Bristol, on the Council of which he sat for some years as the nominee of the Vice-Chancellor of London University. He was local secretary at the Bristol (1875) meeting of the British Association, and took a leading part in all movements for the promotion of science, and especially physical science, in the West of England, where he was well known as a lecturer on such subjects. He was in charge of the chemical and part of the physical investigations of the deep-sea explorations of H.M.S. "Porcupine" of 1869 and 1870, his report on which was printed in the *Proceedings* of the Royal Society. Having determined to devote himself entirely to scientific pursuits, he removed to London in 1881, and was employed by the Gilchrist Educational Trust in delivering popular lectures to very large artisan audiences upon experimental physics, and mainly upon electricity. One set of such courses, intended specially as a popular exposition of the doctrine of the Conservation of Energy, was published in book form, under the title of "Energy in Nature." He also lectured to large audiences in America, Australia, and New Zealand.

Mr. Carpenter was known as a zealous advocate of the introduction of a proper system of teaching elementary science into primary schools, a subject on which he wrote and lectured a good deal, before the Society of Arts and the managers of London Board Schools.

Together with the late Prof. Balfour Stewart he contributed several Papers to the Royal Society on the periodic changes of sun-spots and their connection with terrestrial and magnetic phenomena. He was on the British Association Committee for considering the best means of comparing and reducing magnetic observations. He took a very active part in the Committees of Convocation of the University of London (*e.g.*, on the subject of degrees in engineering). He was member of the Chemical and Physical Societies and of the Institution of Electrical Engineers, and was joint manager with Mr. L. Drugman of the Hanover-square School of Electrical Engineering, which he thoroughly reorganised and brought into line with the leading institutions of the kind in the country.

No one who had the good fortune to be personally acquainted with Mr. Lant Carpenter is likely to soon forget his sympathy with those struggling to the front, and his unvarying courtesy and ever ready assistance to all who came to him. His death will leave a great void in the ranks of the not too numerous army of popular exponents of orthodox science.

## THE NATIONAL TELEPHONE COMPANY.

As a result of the amalgamation of the three principal British Telephone Companies—the National, United, and Lancashire and Cheshire—the Directors of the combined undertaking have had under consideration for some time past various arrangements for the improvement and extension of the telephone service throughout their system.

The London service is so extensive, and some sections are so distant from others, that in order to obviate the faults which have arisen, the Directors of the Company some time back decided to loop the wires, and have also substituted throughout the Metropolitan system improved appliances. The process of looping the wires has also been extended to the outlying districts, and will be gradually brought into use over the entire undertaking. This looping constitutes practically a duplication of the wires, and raises a serious objection where these wires are overhead, and in order to overcome the objection, the Company have decided to petition the local authorities for the necessary permission to place their wires underground where necessary. It will be remembered that many representatives of the London Vestries gave evidence before the Telephone Committee of 1885, and recommended that the telephone trunk wires should be taken underground, and suggested that a combined underground and overhead system would best suit the requirements of the Metropolis. Notwithstanding this, the Company has not been uniformly successful in obtaining the consent of the Vestries to this course, one important Vestry having already declined to act upon the suggestion. The reason assigned for this action by the Vestry in question was that they declined to enter into arrangements with a Company having no statutory authority, and the Directors of the National Company feel strongly that no permanent advance can be made in the telephonic service until the Company is provided by Parliament with statutory powers similar in character to those now enjoyed by railway, tramway, electric lighting, gas, and water companies.

The all-important question of wayleaves is so intimately associated with the granting of statutory powers to the Company, that the Directors are of opinion that unless they are thus enabled to enter into arrangements of a permanent character, their efforts to promote the extension, efficiency, and reliability of the telephone will be greatly hampered. At present their greatest source of anxiety, labour, and expense is the constant withdrawal of wayleaves, and the consequent reconstruction of the routes. It is certainly difficult to see how the Company are to satisfactorily do all that is required to put their service into an efficient state so long as the whole of its construction rests upon the basis of sufferance. The time has, therefore, clearly come when the Company should have its operations facilitated and controlled by statutory powers. The National Company's predecessors, the United Company, applied for statutory powers, but their Bill was, for a variety of reasons, opposed by the Post Office authorities. Now that the Post Office has abandoned for the present the idea of purchasing the telephones, it seems to us that the Department would best serve the public interest by facilitating the progress through Parliament of the Company's Bill, at all events so far as underground wires and the vestries are concerned.

The National Company has already connected up many of the principal Northern and Midland towns with London by telephone trunk wires (at present used from a call office at Oxford-court, Cannon-street, E.C.), and arrangements are in progress to facilitate the use of these wires from subscribers' offices.

So far as the Metropolitan service is concerned, the question of cost is not, perhaps, so much to be considered as the establishment of an efficient, rapid, and reliable service, and we are, therefore, glad to learn that the Company contemplate a very heavy outlay on their London system in the immediate future as an equivalent for the large reductions of rentals announced in the provinces.

The overhead wires originally selected for the telephonic service were of galvanised wire, and weighed 224lb. to the mile, or 12lb. to the span of 100 yards; but this has now been entirely replaced by silicium bronze wire, weighing only 36lb. to the mile, or 2lb. per span of 100 yards. The advantages arising from the use of the lighter wires will be readily appreciated by everyone who considers the effect of a snowstorm upon wires weighing 12lb. per 100 yards.

In view of the competition with which the Company is threatened, and the improvements in telephonic apparatus which the expiry of the master patents may be expected to bring about, it will be interesting to watch the steps taken by the Directors of the National Company to secure themselves in the strong position which they unquestionably occupy.

## INDUCTANCE AND ITS PROPOSED UNIT THE HENRY.*

BY A. E. KENNELLY.

Perhaps the greatest discovery of Faraday's long career of scientific research was that of electro-magnetic induction in the year 1831, when he first brought to light the influence exerted by a magnet or a current upon surrounding matter when subjected to a change of magnetic potential. Oersted had shown that a conductor carrying a current exercised electro-magnetic influence at a distance, and Ampère had enunciated those simple and beautiful laws this influence is admitted to obey, but Faraday's discovery was a great step; it revealed the action of magnetic force in apparently empty space; it inaugurated that deeper insight into the mechanism, still only dimly guessed, which connects matter with all other matter in space; and it invested the all-pervading ether with a dignity and power that, in the hands of many great men since his time, has probably paved the way for our future comprehension of magnetism, gravitation, and radiant energy, while making the hypothesis of action-at-a-distance a mere mathematical conception and process of thought.

The development of this discovery of electro-magnetic induction has practically created electrical engineering, for it is to machinery operating by electro-magnetic induction that we owe nearly every branch of electrical industry except, perhaps, telegraphy, the forerunner of all; and the condition of modern electrical engineering is such that the units and nomenclature relating to steady currents and permanent magnets is insufficient for practical requirements, and the conditions developed by variable currents and magnets demand the establishment of engineering practical units for the purposes of convenience in expression and computation.

Foremost among these required units is that of inductance, or, as it is commonly called, the coefficient of induction. This inductance is a property fully as essential to every electric conducting circuit as resistance and electrostatic capacity, and the inductance of a circuit when conveying variable currents is often a far more important factor in regulating the flow than the ohmic resistance. In fact, we know that Ohm's law does not apply to a circuit so long as the current is unsteady, unless the inductance of the circuit or the counter electromotive force it involves be introduced into the expression.

In conformity with the conventional and so-called absolute units of electro-magnetism, an inductance is a length, and theoretically can always be computed from the geometrical relations of a circuit; that is to say, if the distance of each point from all other points of a circuit be measured, or inferred, in inches or centimetres, the inductance of the circuit will be some definite number of inches or centimetres, capable of being determined by a possible if not a convenient process of summation. If the circuit, however, be associated with iron or other magnetisable matter, then magnetic permeability of the environment will enter the terms of summation as a multiplier. In the absolute centimetre-gramme-second system of units, inductance will be necessarily expressed in centimetres, and the centimetre is thus the natural scientific unit, although unsuited to the requirements of electrical engineering.

It may be well to notice that inductance is only conventionally and perhaps not essentially a length. Prof. Rücker has pointed out† that the multiplication of the permeability factor with the length factor is always tacitly, if not expressly involved, even when the circuit considered is far from magnetisable matter in the ordinary sense; that is to say, when residing in a medium of unit permeability, and therefore the nature of inductance is not merely length, but length multiplied by permeability, while physics has not yet decided whether permeability is the simple numerical factor at present assumed, or a function of length, mass, and time. Until this question is settled, the real nature of inductance must be considered as doubtful, and the fact that inductance will probably, in any event, be always measured by lengths is no more validly an argument as to its

* A Paper read at the fifty-second meeting of the American Institute of Electrical Engineers, New York, December 16, 1890.

† *Phil. Mag.*, February, 1889. Fifth series, Vol. XXVII., p. 104.

Digitized by Google

nature than the usual determination of a body's mass by the earth's gravitational force upon it is an argument that mass is a force. However, the question is one of theory only, and does not affect the consideration of the practical unit.

As has been pointed out by Dr. Sumpner,* there are no less than three ways of defining the inductance of a circuit, or a portion of a circuit, and the three definitions are equivalent when the permeability of the magnetic medium is unity, but are not generally equivalent in the opposite event, being then only related in a definite manner by the magnetic properties of the medium. In other words, the inductance of a hollow solenoid of copper wire, placed in a vacuum and far from all iron, has the same numerical value in each of the three definitions, but if an iron core be inserted in it, its inductance will depend upon the definition selected, and will only be capable of interpretation from its value in one to its values in the others, by taking into account the characteristic permeability curve of the iron, and the conditions of the measurement.

For convenience and general use, however, the secondary definition of Sumpner and Fleming† is probably the best to adopt, and valuations in the other two can be reduced if necessary to this when the data for so doing are available.

The inductance of a circuit or portion of a circuit is then the ratio between the total induction through it to the current producing it. Thus taking a simple helix of five turns carrying a current of two units, and assuming that 1,000 lines of force,‡ passed through the central turn, of which, owing to leakage, only 900 thread the next adjacent on each side, and again only 800 through the end turns, there would be 800+900+1,000+900+800, or 4,400 linkages of lines with the wire, and this being with 2 units of current there would be 2,200 linkages with unit current, and consequently the self-inductance of the helix would be 2,200 centimetres. (Fig. 1.)

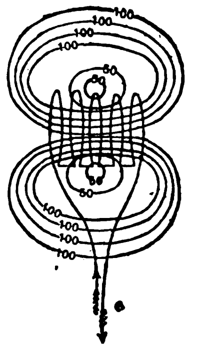

FIG. 1

The fact that such helices are used in galvanometers, and that the magnetic force at any point within them is admitted to be proportional to the strength of the traversing current, renders it evident that had the current in this case been one unit, 2,200 lines linked with the coil would actually have been produced. Supposing, however, that the helix had been wound upon an iron core, the total number of linkages with the same two units of current would have been greatly increased, perhaps twenty-fold, or to 88,000, and the inductance then by the same rule would be 44,000. In this case one unit of current would not in all probability reduce the number of linkages to 44,000, the exact number would depend upon the characteristic curve of the iron core, and the degree of saturation, so that it would now be necessary to state the conditions of the measurement along with result, in order to convey a clear and definite meaning.

It appears anomalous at first sight to state the above inductances in centimetres when they are derived from the number of lines of force, but it is to be remembered that the total number of linkages is divided in each case not by a mere numeric, but by a current, and this quotient can be proved to be a length in the existing system of dimensions.

In the same way the mutual inductance of two conductors is the ratio of the total induction through one of them to the strength of current in the other producing it. Suppose two coils of copper wire to be held in free space far from iron, and let one of them be traversed by a steady current of say four units. Of all the lines of force issuing from this coil, suppose 500 pass through the other coil. For simplicity, imagine the second or recipient coil to be composed of eight turns so disposed that the 500 lines pass through all in succession. There will then be 4,000 linkages of lines with that coil, and the mutual inductance of the two will be 4,000 ÷ 4 or 1000 centimetres. It is interesting to notice that the same result would be reached if the second coil had the current and the linkages were counted in the first, the pair being mutually conjugate in this respect provided they reside in a medium of constant permeability.

Thus far we have only considered the centimetre or absolute unit, whose unfitness for practical use is evident, since the smallest inductance that is at present known to engineering amounts to several thousand, while the average values met with are counted in millions of centimetres. It would, of course, be possible to name suitable units from the metrical system of lengths, but it is the proposal of this institute to adopt the word henry as a practical unit, in honour of the man who, beyond all doubt, was among the foremost to extend the knowledge thus far possessed of self and mutual inductance.

If the selection of the practical unit were entirely free and subservient only to practical requirements, so that its magnitude should express ordinary values in digits with fewest decimals on the one hand, or large numbers on the other, there seems most reason to believe that the thousandth of the earth-quadrant or myriametre would be the most eligible.

| Proposed Name. | Length. | No. of Centimetres. | Unit. |
|---|---|---|---|
| Henry. | Earth Quadrant. | 1,000,000,000 | Practical Unit. |
| | | 100,000,000 | |
| | | 10,000,000 | |
| Millihenry. | Myriametre. | 1,000,000 | |
| | Kilometre. | 100,000 | |
| | Hectometre. | 10,000 | |
| Microhenry. | Decametre. | 1,000 | |
| | Metre. | 100 | |
| | Decimetre. | 10 | |
| | Centimetre. | 1 | Absolute Unit. |

Of course large iron machines employing many turns of wire linked by dense magnetic fields would have inductances more appropriately expressed in earth quadrants, which might then be termed the kilohenry, just as we now have the watt and kilowatt, but there is one restriction which makes such a selection undesirable, and that is the hitherto unbroken system of practical units itself. This practical system is a sub-scheme of the great international C.-G.-S. system, and especially planned for adaptability to practical requirements. It is derived from that parent system by the substitution for the unit of length, one thousand million centimetres in place of one centimetre, and for the unit of mass an impalpable entity definite only in thought, the one-hundred millionth of a milligramme in place of the gramme. By this substitution in the C.-G.-S. electro-magnetic units, we obtain the hitherto unbroken system of the volt, ohm, ampere, coulomb, joule, watt, and farad. Even these units are not always the most convenient, witness, for example, the microfarad in common use, whose prefix is maintained simply in deference to the harmony of the system, for the farad is a capacity that exists only in imagination: the capacity of the earth itself being only about 700 microfarads, and of the sun, or rather a sphere having the apparent dimensions of the sun being only about 76,000 microfarads. On the other hand a proposition has lately been made to infringe the system by making the volt, the ampere, and the watt ten times their present values, on the ground of practical convenience.* However, at the present time, it would surely be unadvisable to attempt the precedent of infringing a system that has hitherto been supported by time, custom, and international Congress.

In this practical system the unit of inductance must be 1,000 million centimetres. That is an earth quadrant or the distance from the pole to the equator, measured on the meridian of Paris. Strictly speaking, it is only the quadrant of the French standard earth, which is about one-tenth of one per cent. shorter than the acknowledged actual earth quadrant, according to the best determinations, but the fact of the latter being 10,001 kilometres instead of 10,000 is a matter of precision in definition only and in no way affects the practical unit.

As regards the history of the subject, it would appear that prior to 1887 measurements and deductions were confined to scientific works, and were expressed in absolute units—centimetres. In that year, however, a Paper was read before the British Institution of Electrical Engineers by Messrs. Ayrton and Perry,† who invented and developed a practical measuring instrument for the measurement of inductance, who, aided by Dr. Sumpner, made important contributions to the literature of the subject, and who proposed a name provisionally for the practical unit. That name was the secohm, a contraction of second-ohm, implying the fact

* *Phil. Mag.*, June, 1888. Fifth series. Vol. XXV., p. 453.

Digitized by Google

that the product of the two was the length equal to the practical unit. They drew attention to the fact that since the Paris Congress of 1884 had fixed the standard legal ohm as the resistance of a column of mercury at zero centigrade, 106 centimetres long and one square millimetre in cross section, whereas the true ohm was in all probability 106·3 centimetres, or one-quarter of one per cent. greater, the inductances measured in the manner they suggested from seconds and legal ohms, would be in terms not of the standard earth quadrant of 10,000 kilometres, but of legal earth quadrants 9,778 kilometres in length. The difference practically is not very great, but to avoid error or confusion in definition they advocated provisionally the term secohm in place of quadrant.

The Paris Congress of 1889 adopted the "quadrant" as the practical unit of inductance, defining it as 1,000 million centimetres.

The practical range of inductances is second only to that of resistances, and the latter we know from a few microhms up to thousands of megohms. The smallest inductances are those of Hertz resonators which descend to the order metres. Excluding these, however, the smallest are, perhaps, met with in measuring instruments intended to have negligibly small inductance, such as doubly-wound resistance coils, Cardew voltmeters, and the like. These descend to the order of decametres, and can generally be expressed as such without prefixing decimal points. It is evident that the term microhenry would suitably apply to their designation. At the other end of the scale we find large induction machines linking dense fields with many turns of wires, and reaching inductances of hundreds or even thousands of henrys. Intermediate between these limits, there exists a large class of circuits having many turns but little iron, or clad in iron with few turns of wire, and these seem to be best expressed by the term millihenry, equivalent to the myriametre.

With the object of setting forth the advantages to be derived from the use of this nomenclature, it may be permissible to adopt it provisionally in describing the measurements that follow. These measurements have been made on different types of apparatus at different times and by different methods, so that they represent mean values from several observations in many cases, but allowance must be made for the variations of standard and type.

In telegraphy, the inductance of an ordinary Western Union 140-ohm relay is about three henrys with the armature drawn well back, and nine henrys with the armature pressed against the poles, in the latter case, of course, the magnetic reluctance of the iron circuit is a minimum, and the same current in the coils causes three times as many lines to circulate through the iron. At the position of the armature in ordinary adjustment the inductance is about five henrys.

The inductance of an ordinary standard 10ω relay is from 200 to 500 millihenrys, according to the position of the armature relatively to the poles.

The inductance of an ordinary sounder is similarly from 25 to 50 millihenrys. These inductances are the values obtained with only a few milliamperes through the coils, and since the path of the induction is largely through iron, the inductance varies with the strength of the current used. Practically, however, the variation is small within the range of current at which instruments usually operate.

*(To be continued.)*

## ELECTRO-MAGNETIC MECHANISMS.

### PRESIDENTIAL ADDRESS TO THE JUNIOR ENGINEERING SOCIETY.

BY PROF. SILVANUS P. THOMPSON, D.SC., B.A.

*(Continued from page 241.)*

*Cycle of Operations in the Stroke of an Electro-Magnet.*

Passing from the properties of the material to those of a definite electro-magnetic apparatus, the cycle of relations between magnetising force and magnetism may be still traced out by means of diagrams. Fig. 4 relates to a certain horse-shoe electro-magnet. The curve O P represents the ascending curve of the electro-magnet, when its armature was about one-twenty-fifth of an inch away. Under these circumstances, owing to the reluctance to magnetisation of the air gaps, a given magnetising power (ampere-turns of circulation of current) will produce less magnetisation than if the magnetic circuit were closed. The second curve Q R is the descending curve of the same electro-magnet when the armature is close up to the core, closing the magnetic circuit. Now, suppose such an electro-magnet to be used to do the work of drawing up its armature. We may consider the successive operations of producing a complete stroke, exactly as the engineer discusses the cycle of operations in the stroke of the piston in the cylinder. Starting at O, with the armature away from the core, the magnetising current is turned on, and the magnetisation is carried to the point corresponding to P. Suppose, now, the armature is allowed to move up to the core. The magnetisation is increased because of the more perfect condition of the magnetic circuit. During the movement of the armature mechanical work is performed, and as the magnetising power is kept all the time at a constant value, the line P Q represent (magnetically) this operation. If, now, the magnetising current is cut off the magnetisation follows the right-hand descending curve to R. During this operation a certain amount of energy is restored magnetically. If, now, the armature is permitted to fly back to its initial position, thus opening the gaps in the magnetic circuit the residual magnetisation will disappear almost entirely (provided the iron is soft), and the energy it represents is wasted as heat. The area O P Q R O represents the whole quantity of energy magnetically applied to the system. Part of this O Q R O is wasted by hysteresis; the other part O P Q O is utilised in doing mechanical work. As a matter of fact, these four operations do not occur separately in a stroke; for the armature usually begins to move before the magnetism has grown up to the point P, and it begins to fly back before the residual magnetism has entirely disappeared. The actual cycle is not made up of two straight lines and two magnetic curves any more than the actual diagram on the indicator card of a steam engine consists of the two isothermals and two adiabatics of the ideal case.

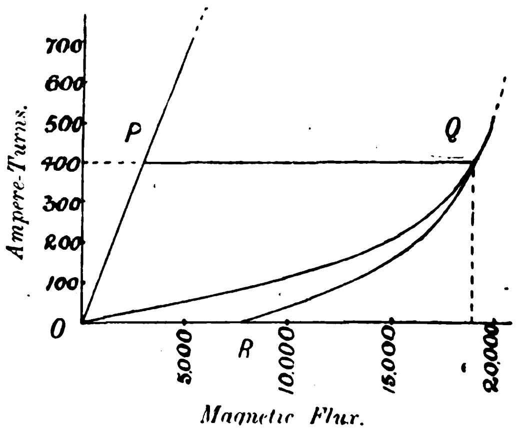

Fig. 4.

As a matter of fact the motion of the armature itself sets up in the copper wire an induced electromotive force which tends to diminish the magnetising current during the time that the motion lasts. The efficiency of the arrangement as an engine depends indeed upon the magnitude of such counter-electromotive forces, and upon the degree to which they cut down the working current. But this diagram does not represent the electrical losses; it exhibits solely the magnetic quantities concerned. Were a greater amount of time available, one might enlarge upon the mode in which the energy is transferred electrically to the magnetic system; how the approach of the armature, by increasing the magnetic induction as it completes the magnetic circuit sets up counter-electromotive forces, the electric energy utilised being proportional to the integral product of the current into the counter-electromotive force so generated. This is too wide a field for discussion at the present moment.

It might also be pointed out that this diagram does not exhibit the mechanical value of the force at any part of the stroke. During the part of the stroke corresponding to P Q, in which the armature is approaching the core there is an ever-increasing pull. On the other hand, during the return stroke the magnetism is undergoing the transition from R to O, and work is being done upon the armature instead of by it. There is an analogy, however, here also to Carnot's cycle diagram. That diagram does not exhibit the thermal quantities concerned in the different parts of the cycle. Heat is taken in along one of the isothermals and rejected along the other, but the length or position of those isothermals does not exhibit the quantities thus supplied to the engine or expelled from it. Heat values are not exhibited upon the Carnot diagram of mechanical work; neither are mechanical values exhibited upon my diagram of magnetic work.

*The Essentials of Electro-magnetic Engineering.*

It will be evident from what I have already said that amongst the most essential matters with which an electro-magnetic engineer must be conversant, are the properties of iron and the principle of the magnetic circuit. No inconsiderable part of the training of the mechanical engineer is devoted to acquiring a know-

Digitized by Google

ledge of the mechanical properties of materials; expensive and elaborate testing machines are devised for investigating those properties. The numerical values ascertained by such tests enter into every calculation of structures; affect every point in the design of machinery. For the electro-magnetic engineer there is, indeed, the double study not only of the magnetic properties of iron, but of the electric properties of the copper. He has to be thoroughly acquainted with the laws governing the generation and flow of electric currents; an acquaintance not to be made second-hand from books or lectures. Doubtless a complete experimental knowledge of these things may be facilitated by judicious teaching. Analogies are often helpful. No excuse is therefore needed for introducing the following table of analogies concerning the matters which are akin in several branches of engineering :—

| Mechanical. | Hydraulic. | Electrical. |
|---|---|---|
| Force | Pressure | Volts (pressure) |
| Rate of Displacement of mass (lbs. per min.) | Quantity of flow (Gals. per min.) | Amperes (current) (Coulombs per sec.) |
| Friction (coefficient of) | Fluid friction (coefficient of) | Ohms (resistance) |
| Inertia of mass | Inertia of mass | Quads(self-induction) |
| Elasticity | Compressibility | Farads (capacity) |

One of the most strange things about electricity, which until recent years can scarcely be said to have been comprehended, is this: that although electricity, when at rest, apparently possesses no weight, and occupies no space, yet, when it is moving along in a wire as a current, that current possesses a species of inertia. Still more strange is it that the inertia of the current apparently resides not in the copper wire within which the so-called current is flowing, but in the space outside the wire, and depends on the external medium. The inertia of an electric current flowing along in a copper wire is less if the surrounding medium is air than it is if the surrounding medium is iron. This inertia effect is, indeed, inextricably mixed up with the fact that the current sets up a magnetising action in the medium surrounding it. Our electromagnets are examples of spaces filled with iron, entirely exterior to the copper wire in which the electricity flows, nevertheless, being magnetised by that flow of electricity, and acting as an inertia-drag upon it.

Supposing these things, magnetic and electric, to be mastered, there remains yet one piece of practical education of the highest importance to the electro-magnetic engineer, namely, how to convey an electric current and to confine it to its proper channel. The proper jointing of electric conductors is relatively a much more important matter than the rivetting of girders, the splicing of belts, or the wiping of plumbers' joints. And the problem of properly insulating an electric conductor is much more difficult than that of preventing leakage of water, gas, or steam. To make things water-tight, or steam-tight, is a comparatively simple matter. To make things properly electric tight is by no means so easy, especially when high electric pressures are employed. To insulate an electric conductor is a fine art. The materials employed must be not only electrically non-conducting, but mechanically capable of resisting the (electric) stresses to which they are subjected. Moreover, these same stresses, acting as mechanical tensions at right angles to the surfaces of the copper conductors, combined with mechanical pressures in all directions parallel to those surfaces, are proportional, not to the electric pressure, but to the square of it. Thus, Mr. Ferranti, supplying certain districts of London by electric mains from Deptford at an electric pressure of 10,000 volts, has to provide adequate insulation capable of resisting being pierced by tensions which are 25 times as great as those that would arise if the conductors were worked at a pressure of 2,000 volts only. The insulator must mechanically resist being broken down by a spark piercing it. Adequate mechanical resistance is an absolute necessity, quite apart from any apparent value of its so-called electrical resistance. The electro-magnetic engineer must understand all about this.

But in addition to any mechanical knowledge he may possess, and beside all the practical experience he may acquire about the behaviour of electric currents and changes at various pressures, he must acquire, as my discourse to-night will have shown you, a thorough knowledge of the purely magnetic branch of the subject. You cannot ignore the fact that much of this knowledge is quite of recent date: is not yet possessed by any very large number of men. There are, as yet, very few shops or factories where a young engineer can pick up a knowledge of these things. They are not like the ordinary matters of mechanical engineering, things to be learned anywhere, and known to thousands of trained men. Indeed, I think I am putting forward no unfair claim when I say that it is to the technical colleges of one description or another that the majority of young engineers must, in the present state of the industry, betake themselves if they wish to make a full acquaintance with the principles, not to say the practice, of electro-magnetic engineering. Not that there do not exist factories and shops where this branch of the great engineering industry is carried on, and where an admirable practical training is to be had; but these are relatively few, and hence entrance to them is a matter of some difficulty.

*Experiments on Magnetic Circuits.*

Returning to the principle of the magnetic circuit, I will now illustrate by experiments the important principle which I have already enunciated that the circuit always tends so to alter its configuration as to better its form and close up all gaps. The cylindrical iron plunger which I showed you a few minutes ago is sucked into the tubular coil in virtue of this very principle. It tends to settle down with both ends equally protruding, for in this position it best affords a passage for the magnetic lines which leak back outside invisibly, through the air, from one end of the plunger to the other. Coned plungers act a little differently; their range of action is somewhat more extended. With them the maximum pull occurs not when the apex is just protruding through the coil, but after it has protruded some distance; and the final position in which they tend to settle is one in which the apex end protrudes much further out of the coil than the broad end protrudes.

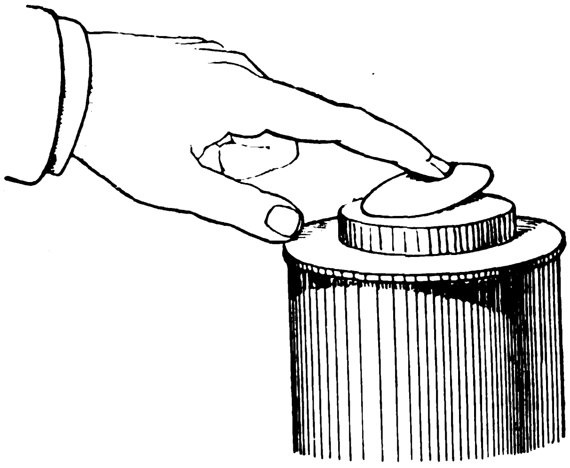

FIG 5.

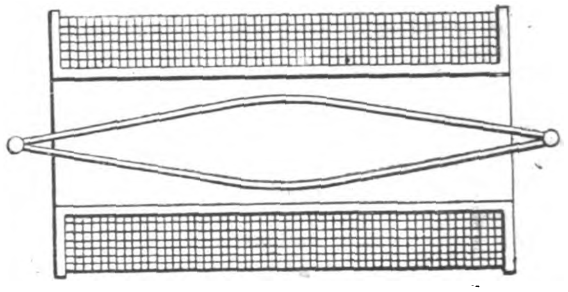

FIG. 6.

Here I have an electro-magnet consisting of a vertical cylindrical core about 12in. long and 3in. in diameter, surrounded by a coil of copper wire. When I turn on the current the magnetic circuit must complete itself in a very imperfect way by an invisible fountain of magnetic lines streaming up mostly through the top face and turning down on all sides in curved paths. Obviously these magnetic lines, where they emerge through the top surface, will crowd toward the periphery, rather than come up through the centre, so that they may traverse as short a route as possible. One would therefore expect to find, if one explored the top surface with an iron bullet, that the bullet is attracted more powerfully at the edges than at the middle part. It is a very easy thing to try this with a spring-balance to which the bullet is hung; but it is still more readily shown to an audience in another way. Here is an iron ball, about 1½in. in diameter. If I place it on the top of the electro-magnet it immediately rolls to the edge—taking that position where it helps most to complete the magnetic circuit. If I now transfer my iron ball to this large electro-magnet, which has two cylindrical cores, each about 2in. in diameter and 11in. high, connected at the bottom by an iron yoke, I find that the ball placed on the end of either core invariably rolls to the innermost point on the periphery nearest to the other core; for in this position it most nearly fills the gap between the poles.

Let me show you in this same connection a strange and paradoxical experiment with the same vertical cylindrical electro-

Digitized by Google

magnet that I used a moment ago. Its top surface is about 3in. in diameter. Here is a disc of tin-plate nearly 2½in. in diameter. Every engineer knows that tin-plate is made of iron, tinned upon its surface; and every engineer will therefore be quite ready to believe that if I lay this little disc of tin-plate down upon the middle of the circular surface of the electro-magnet, and then turn on the electric current, the little disc will be held tightly down. But will it? Not by any means. Instead of sticking itself down you will see it jump suddenly over and lie down, overhanging the edge. It tries to get into such a position that it improves the circuit. I replace the disc of tin-plate by a thinner disc of ferro-type iron (Fig. 5), and you notice how it actually bends up under my finger in its effort to turn over and get away from its central position.

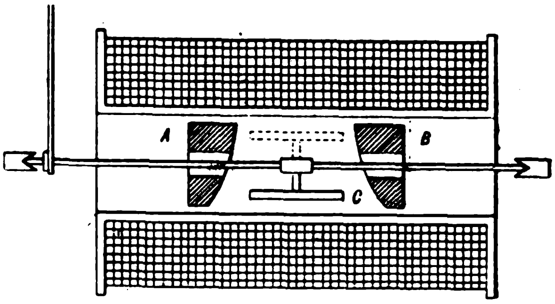

FIG. 7.

Not less strange is the action exhibited by the apparatus before you, consisting of an iron tube, surrounded by a coil of wire, and having two short iron cores inserted in the ends of the tube. You expect these cores to be drawn in when the electric current is made

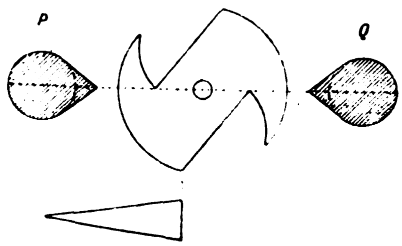

FIG. 8.

to circulate around the tube. Not a bit of it! There is iron already—the tube—through the coil, and the short cores will best complete the circuit not by being drawn in, but by being pushed out. I turn on the current, and they instantly protrude. Two light

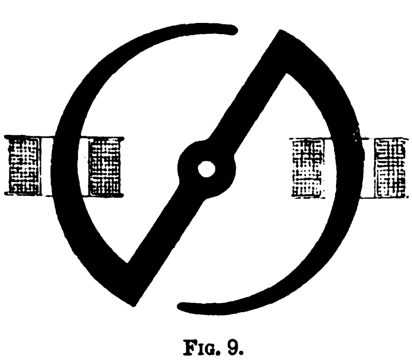

FIG. 9.

pendulums of wood are placed opposite to them, so that you may see at a distance how the cores are urged outwards. This apparatus was devised by Mr. Shelford Bidwell, who also has lent me another model, illustrating the same principle (Fig. 6). This consists of two strips of thin springy sheet iron joined at the ends, but bowed outwards. If this is placed inside a magnetising coil it elongates itself when the current is turned on. If, on the contrary, you place within the coil two separate flat strips tied together at their middle they tend to open out at their ends when the magnetising power is applied, for by opening out they can best help the magnetic lines to find return paths through the air. There is a whole class of small pieces of mechanism, used chiefly in the construction of ampere-meters and such-like instruments, depending on this same principle of an apparent magnetic repulsion. Several of the sheet diagrams on the wall relate to these devices.

In another instrument (an ampere-meter) devised by Mr. Evershed, a small piece of iron, C (Fig. 7), pivotted upon an axis, is attracted round, parallel to itself, into a position between the curved cheeks of two other pieces of iron; A and B, all being enclosed within a tubular coil of copper wire. Another way of carrying out the same idea is shown in Fig. 8, where a curiously wrought central piece of iron, R, having two wedge-shaped tongues—one of which is shown below in an edge-view—is placed between the poles, P and Q, of an electro-magnet. This central piece tends so to turn as to bring into the direct line between the poles the greatest possible thickness of iron.

One of the latest devices for procuring a rotatory movement electro-magnetically is depicted in Fig. 9. Here there are two magnetising coils, each with an aperture through its middle. The iron cores are both coned, and joined together so as to constitute portions of the rim of a wheel. They tend to plunge deeper and deeper into their respective coils.

[ERRATUM. In FIG. 3., p. 241, the letters B and H have been interchanged from their proper positions.]

*(To be continued.)*

## SUMMARY OF ELECTRICAL EVENTS FOR 1890.

JANUARY.

The St. Pancras Vestry resolve, by 38 votes to 16, to obtain plans, specifications, and tenders for the supply of electricity for 10,000 10 candle-power incandescents and 90 arcs (1st).

An 18,000-light Edison station in Pearl-street, New York, destroyed by fire (2nd).

Death of Mr. Charles Lever (5th).

Death of Father Perry, well known for his researches in terrestrial magnetism.

Presidential address on "Magnetism" by Dr. John Hopkinson, the newly-elected President of the Institution of Electrical Engineers (9th).

Cessation of the overhead wire cutting in New York.

Paper on "Galvanometers" read before the Physical Society by Prof. Ayrton (17th).

The Brighton Town Council decide, by 35 votes to 3, to establish electric lighting works at a cost of £30,000 (23rd).

Lecture by Prof. Dewar, at the Royal Institution, on "The Scientific Work of Joule" (24th).

Important experiments by MM. Sarasin and de la Rive on multiple resonance in connection with electric oscillations.

The contract for the electric lighting of the eastern division of the City awarded to the Laing, Wharton, and Down Construction Syndicate (28th).

Introduction of the electric light at the Public Record Office.

Inauguration of the new electric light installation at the British Museum—137 arcs, 827 incandescents (28th).

Cantor Lectures on "The Electro-magnet," by Prof. Silvanus Thompson.

Considerable agitation on the part of the American telephone companies against the single-trolley system of electric traction.

Dividends declared: Anglo-American Telegraph Company, 2¾ per cent.

FEBRUARY.

Meeting of the National Electric Light Association at Kansas City (11th to 14th).

Paper on "The Theory of Armature Reactions in Dynamos and Motors," by James Swinburne, read before the Institution of Electrical Engineers (13th).

Draft of a Bill establishing a system of Government telegraphs presented by Postmaster-General Wannamaker to a Committee of the United States House of Representatives.

Paper on "Some Points in Dynamo and Motor Design," by W. B. Esson, read before the Institution of Electrical Engineers (20th).

M. Auguste Frei, Director of Swiss Telegraphs, appointed Director of the International Telegraph Bureau at Berne.

An electrical engineering scholarship, within the gift of the Council of the Institution of Electrical Engineers, founded by Sir David Salomons.

Dividends declared: Direct Spanish Telegraph Company, 5½ per cent.; Taunton Electric Lighting Company, 5 per cent.; India-rubber Gutta-percha and Telegraph Works Company, 10 per cent.; Indo-European Telegraph Company, 10 per cent.

Digitized by Google

MARCH.

Action commenced by the Edison Electric Light Company against the United States Illuminating Company of New York for alleged infringement of Edison's "electromotor" meter patent of 1881; the infringing meter being the Schallenberger alternate current "induction" meter (4th).

Death of Mr. W. H. Snell, Editor of the *Electrician* (5th).

Public trial of the electric locomotives on the City and South London Railway (5th).

Deputation to the Board of Trade from the Association of Municipal Corporations. The Board of Trade agreed to the insertion of clauses in municipal Orders giving local authorities power to transfer their Orders, but declined to allow local authorities to divest themselves of all responsibility.

The question of the Government purchase of the telephones raised in the House of Lords by the Duke of Marlborough (15th).

Lecture on "Electro-Magnetic Radiation," delivered at the Royal Institution by Prof. G. F. Fitzgerald (21st).

Publication of the result of the Paris electric meter competition.

Important statements made by the chairman (Mr. J. S. Forbes) at a meeting of the shareholders of the London Electric Supply Corporation, with regard to the position of affairs at Deptford (31st).

Death of Herr Johann Georg Halske, one of the founders of the firm of Siemens and Halske, of Berlin.

Important decision rendered in the United States District Court, sustaining the broad claim of the Brush Company to a storage battery wherein the active material is applied to the plates by any mechanical means whatever.

Dividends declared: Eastern Extension Telegraph Company, 7 per cent.; Telegraph Construction and Maintenance Company, 20 per cent.

APRIL.

Large contract concluded for an electric railway on the Short System at Rochester, N.Y.—100 cars, dynamo capacity of station to be 1,100 horse-power.

Paper on "Signalling across Rivers in India," by Mr. W. F. Melhuish, read before the Institution of Electrical Engineers (10th).

The streets of Chelmsford lighted for the first time by electricity —18 2,000-candle-power arcs and 210 32-candle-power incandescents (14th).

Paper on "Electric Welding," read before the Institution of Civil Engineers by Sir Frederick Bramwell (15th).

Earl Compton moved in the House of Commons, "That, in the opinion of the House, the present position of telegraphists in London and elsewhere is unsatisfactory, and their just grievances require redress." Motion rejected by a majority of 39 in a House of 245 (15th).

The Paris municipality decree the expulsion of foreign steam and electrical plants from the Paris central lighting stations.

Annual general meeting of the Electrical Trades Section of the London Chamber of Commerce (21st).

The Central London Railway Bill came before a Select Committee of the House of Commons (21st).

Paper on "A Lightning Guard for Telegraph Purposes, and on the Protection of Cables from Lightning," read before the Institution of Electrical Engineers by Dr. Oliver Lodge (24th).

Bill to amend the Electric Lighting Acts introduced into the House of Commons (28th).

Local Government Inquiry into the proposed Brighton municipal electric lighting scheme (29th and 30th).

Paper on "Electric Traction Data," by Mr. Reckenzaun, read before the Old Students' Association (30th).

Dividends declared: Western and Brazilian Telegraph Company, 4 per cent.; Great Northern Telegraph Company, 5 per cent.

MAY.

Opening of the Edinburgh Exhibition (1st).

A deputation from electric light supply companies approached the President of the Board of Trade on the subject of the clauses which the Board proposed to insert in the Provisional Orders of local authorities (2nd).

The Select Committee of the House of Commons decide in favour of the Central London Railway Bill (6th).

Duplication of the cable communication between Australia and New Zealand.

Sir John Pender, in a letter to the Agents-General of the Australasian Colonies, offers to reduce the Australasian cable tariff to 5s. per word for one year by way of experiment, provided that the Colonies guarantee half of any loss that the cable companies suffer (13th).

Death of M. Jacques-Louis Soret, the eminent French physicist (13th).

Lecture by Dr. Fleming at the Society of Arts, on Prof. "Elihu Thomson's Electro-Magnetic Induction Experiments" (14th.)

Demonstration of the Worms-Balé process of tanning by electricity at the Works of the British Tanning Company (14th).

Royal Society Soirée (14th).

Opening of the International Telegraph Conference in Paris (16th).

The Intercolonial Conference on Postage and Cable Rates, sitting at Adelaide (South Australia), decide to accept the modified proposals of Sir John Pender for the reduction of the Australian cable rates to 4s. per word, on the condition that the Imperial Government consent to pay one-half of the subsidies and guarantees payable to the companies.

Meeting of the American Institute of Electrical Engineers at Boston (19th).

An important Paper on "Life and Efficiency of Arc Light Carbons," read before the American Institute of Electrical Engineers by Mr. Louis E. Marks (21st).

Death of M. Daniel Napoli, head of the laboratory of the Eastern Railway Company of France (29th).

Dividends declared: Consolidated Telephone Construction and Maintenance Company, 6 per cent.; Hastings and St. Leonards-on-Sea Electric Light Company, 3 per cent.

JUNE.

Announcement in the House of Commons by the Postmaster-General that the Government do not intend to purchase the telephones (20th).

Close of the International Telegraph Conference at Paris (21st).

Inauguration of the Public Lighting of the streets of Bath by electricity, 81 1,200 candle-power arcs being employed (24th).

Rejection by the House of Commons of the Overhead Wires Bill promoted by the London County Council (26th).

Death of M. Auguste Frei, Director of the International Telegraph Bureau at Berne.

Death of Mr. John Bordeaux, Chief Engineer to the Submarine Telegraph Company.

The Local Government Board sanction the borrowing of £32,500 by the Brighton Corporation for the purpose of carrying their electric lighting scheme into effect.

Notices of intention to apply for Provisional Orders to the number of 263 served upon Local Authorities.

JULY.

Royal Assent given the Electric Lighting Acts Amendment Bill (Scotland) (4th).

The tenders in connection with the proposed municipal central station accepted by the Brighton Town Council (10th).

The three Australian cables of the Eastern Extension Company interrupted by an earthquake (10th).

Publication of the revised regulations relating to the pay, leave, &c., of the Postal Telegraph clerks (14th).

Meeting of the Institution of Electrical Engineers at the Edinburgh Exhibition (15th, 16th, 17th). Papers read: "Working Efficiency of Secondary Cells." By Prof. Ayrton. "Observations on currents originating in Ordinary Aerial Telegraph Conductors." By A. R. Bennett. "Some of the Chief Features of the Edinburgh Exhibition, and mainly of the Electrical Section." By Dr. R. Mullineux Walmsley.

Judgment given in the First Division of the Court of Session in the action brought by Messrs. King, Brown and Co., to reduce the compound-winding patent, No. 2,003, of 1878, belonging to the Brush Electrical Engineering Company. The decision of Lord Trayner, invalidating the patent, was upheld (16th).

The House of Lords Committee decide that the preamble of the Central London Railway Bill is not proved (16th).

Explosion in the battery room of the New York offices of the Western Union Telegraph Company; a disastrous fire ensued, and damage to the amount of 250,000 dols. was done before it could be extinguished. The telegraphic service was greatly crippled (18th).

The appeal of Mr. John Dixon Gibbs and the National Company for the Distribution of Electricity by Secondary Generators against the decisions of Mr. Justice Kekewich (9th July, 1888) and of the Court of Appeal (4th March, 1889), invalidating the Gaulard-Gibbs transformer distribution patent, No. 4,362 of 1882, came before the House of Lords on the 25th inst., with the result that the judgments below were affirmed, and the appeal was dismissed.

Digitized by Google

Dividends declared: Crompton and Co., 5 per cent.; Direct United States Cable Company, 3½ per cent.; Eastern Telegraph Company, 6½ per cent.; Edison-Swan United Electric Light Company, 7 per cent. ("A" shares); National Telephone Company, 6 per cent.

AUGUST.

Completion of the Southend Pier electric tramway (2nd).

Execution of Kemmler by electricity, Auburn Prison, New York (6th).

The Grande Medaille d'Ampère awarded to M. Gramme by the Société d'Encouragement for his invention of the Gramme ring; the same Society also awarded the Giffard prize of 6,000 francs to M. Ferdinand Carré for his improvements in the manufacture of arc light carbons.

Meeting of the National Electric Light Association at Cape May (19th).

Publication of the Board of Trade Safety Regulations (21st).

Publication by the Board of Trade of a list of the electric lighting Provisional Orders granted by them and confirmed by Parliament during 1890. Total, 74: Local Authorities, 43; Companies, 31. The following are the Local Authorities who obtained electric lighting powers:—Aberdeen, Accrington, Ayr, Bacup, Barnsley, Bedford, Belfast, Birkenhead, Blackburn, Blackpool, Burnley, Burton-on-Trent, Bury, Cambridge, Cheltenham, Chester, Darlington, Derby, Dover, Dundee, Glasgow, Great Yarmouth, Hastings, Hove, Huddersfield, Kingston-on-Hull, Lancaster, Leicester, Malvern, Manchester, Nottingham, Oldham, Portsmouth, Salford, Stafford, Stockton-on-Tees, Tiverton, Walsall, Wigan, Wolverhampton, Worcester, York.

Dividends declared: General Electric Company, 7½ per cent.

The Local Authorities of the following towns resolve to obtain Provisional Orders: Canterbury, Kidderminster, Llanelly.

SEPTEMBER.

Meeting of the British Association at Leeds (3rd).

The streets of Fareham (Hants) lighted by electricity; 21 1,200-candle-power arcs and 85 20-candle-power incandescents (8th).

Publication of Prof. J. A. Ewing's molecular theory of induced magnetism.

Opening of the first Westinghouse electric railroad at Lansing (Mich.).

National Telephone Convention at Detroit (9th).

Meeting of the Association of Edison Illuminating Companies at Minneapolis (16th).

Accident to an electric tramcar running between Florence and Fiesole, by which five persons were killed and twenty injured (24th). Accident due to the driver omitting to switch off the current on going down hill.

At a meeting of the Emperors of Germany and Austria at the Castle of Rohnstock, in Silesia, selections from "Carmen" and other operas were transmitted by telephone from Berlin, a distance of 250 miles.

The Local Authorities of the following towns decide to apply for electric lighting Provisional Orders: Bromley, Edinburgh.

OCTOBER.

Death of Mr. C. H. Gimingham (2nd).

Approval by the Swiss and Bavarian Governments of the plans for applying two-thirds of the water of the Rhine, near Rheinfelden, to the generation of electricity for the purpose of the distribution of power.

Meeting of the National Street Railway Association at Buffalo. Electric traction much discussed.

The Local Authorities of the following towns resolve to obtain electric lighting Provisional Orders: Croydon, Dewsbury, Exeter, Gloucester, Gravesend, Hanley, Monmouth, Paisley, Sunderland, Weston-super-Mare, Whitby.

Dividends declared: Brazilian Submarine Telegraph Company, 7½ per cent.; Woodhouse and Rawson United, 15 per cent.

NOVEMBER.

Close of the Edinburgh Exhibition (1st).

Inauguration of the City and South London Railway by the Prince of Wales (4th).

Laying of the foundation-stone of the Brighton Municipal Central Station (4th).

Shutting-down of the Grosvenor Gallery Station and transference of the entire load to Deptford.

Laying of the foundation-stone of the St. Pancras Municipal Central Station (5th).

At a meeting of the Committee of the Electrical Trades Section of the London Chamber of Commerce it was unanimously resolved that the Chairman should be requested to bring the whole question of the Board of Trade regulations, issued in August, before the Council of the Chamber with a view of getting the Council to move in the matter (10th).

Paper on "The Chemistry of Secondary Cells," read by Prof. Ayrton before the Institution of Electrical Engineers (13th).

Destructive fire at the Grosvenor Gallery transformer sub-station, resulting in the cessation of the electric supply for over a fortnight. The fire was caused by the arcing of a plug switch, due to a nervous employé withdrawing the plug instead of pushing it home when engaged in switching in a bank of transformers (15th).

Permission given by the Leeds County Council to the Thomson-Houston agents to run some experimental electric cars on the Roundhay Park line.

The London, Manchester, Liverpool, and Birmingham telephone trunk wire opened to the public (19th).

Large reduction of telephone rentals announced by the National Telephone Company at Liverpool, Birkenhead, Newcastle, and other large towns in the North. These reductions to take place on and after January 1, 1891.

The series tramway line at Northfleet ceased running.

Conversazione of the Institute of Electrical Engineers (19th).

The Hammersmith Vestry agree to the working of the Uxbridge-road-Kew tramway by the Lineff closed-conduit system of electric traction (20th).

Second Annual Dinner of the Institution of Electrical Engineers (20th).

Presidential address to the Junior Engineering Society, by Prof. Silvanus Thompson, on "Electro-magnetic Mechanisms" (21st).

Dr. Rothen appointed Director of the International Telegraph Bureau at Berne.

The Governments of Victoria, New South Wales, South Australia, and Western Australia decide to propose to their respective legislatures the adoption of the cable guarantee required by the Eastern and Eastern Extension Companies to enable them to put in force the projected reduced tariff.

The new cable of the Great Northern Telegraph Company, between Newbiggin and Newcastle, opened to the public (22nd).

The Local Authorities of the following towns resolve to obtain electric lighting Provisional Orders: Harrogate, Kingston-on-Thames, Southend, Southport, Stockport, Tynemouth.

Dividends declared: Electric Construction Corporation, 6 per cent.; Swan United Electric Light Company, 10 per cent; Blackpool Electric Tramway Company, 7½ per cent.

DECEMBER.

Anniversary meeting of the Fellows of the Royal Society; Sir William Thomson elected President; presentation of the Rumford Medal to Professor Hertz for his researches in electro-magnetic radiation, and of a Royal Medal to Dr. John Hopkinson for his researches in magnetism and electricity (1st).

Formation of the American Tanning Company of New York for the purpose of introducing the Worms and Balé process of tanning by electricity into the United States.

The Barnsley Town Council enters into a contract with the Westinghouse Company.

Breakdown of the transformers at the Grosvenor Gallery sub-station and stoppage of the supply (3rd).

Death of Mr. H. G. Erichsen of the Great Northern Telegraph Company (6th).

Watt *v.* Maxim Electric Company and Maxim Electric Company *v.* Watt. Mr. Hugh Watt, M.P., to return £1,000 to the Company and pay costs (8th).

Expiry of the Bell Telephone patent (9th).

Paper on "The Electric Lighting Progress in London," read before the Society of Arts by Mr. Frank Bailey (10th).

Election of the President and Council of the Institution of Electrical Engineers for the year 1891. Award of premiums: Institution premium, W. B. Esson; Paris Exhibition premium, W. F. Melhuish; Fahie premium, K. L. Murray. President for 1891, W. Crookes, F.R.S (11th).

A Paper on "Some Experiments with Selenium Cells," read before the Physical Society by Mr. Shelford Bidwell, F.R.S.; a paper on "Alternate Current Condensers," read before the same Society by Mr. James Swinburne (12th).

Digitized by Google

The contract for the lighting of the western district of the City awarded to the Brush Electrical Engineering Company (17th).

Swansea Corporation accept the tender of Crompton and Co. for arc lighting (17th).

The City and South London Railway opened to the public (18th).

Seventy applications for Provisional Orders lodged with the Board of Trade (21st), 37 of which were lodged by Local Authorities.

Appointment by the Board of Trade of a Committee "To consider whether any, or if so, what, steps should be taken for the provision of Electrical Standards." The Committee comprised: Sir W. Thomson, Lord Rayleigh, Prof. Carey-Foster, Mr. R. T. Glazebrook, Dr. John Hopkinson, Prof. W. E. Ayrton, Mr. W. H. Preece, Mr. E. Graves, Major Cardew, R.E., and Mr. Courtenay Boyle; Sir Thomas Blomefield acting as Secretary (23rd).

Death of Mr. Wm. Lant Carpenter (23rd).

*From the forthcoming 1891 Edition of "The Electrician" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.*

## ELECTRIC LIGHTING NOTICES FOR 1891.

The following is a corrected list of the applications for Provisional Orders deposited with the Board of Trade on or before 21st December, 1890. An asterisk (*) indicates that the gas supply is in the hands of the applicants :—

### THE METROPOLIS.

ACTON LOCAL BOARD apply for an Order for Acton.

BRUSH ELECTRICAL ENGINEERING COMPANY make application for three Orders—(1) St. Leonard, Shoreditch ; St. James and St. John, Clerkenwell ; and St. Luke, Old Street ; (2) St. Saviour, Southwark ; (3) A portion of the City of London.

CAMBERWELL AND ISLINGTON ELECTRIC LIGHT AND POWER SUPPLY, apply for two Orders—(1) A portion of the parish of St. Giles Camberwell ; (2) St. Mary, Islington.

CHISWICK LOCAL BOARD—Chiswick.

EALING LOCAL BOARD apply for an Order for Ealing.

NEW CADOGAN AND BELGRAVE ELECTRIC SUPPLY COMPANY apply for one Order to supply electricity in portions of the parishes of St. Luke, Chelsea, and St. George, Hanover Square.

LAING, WHARTON, AND DOWN.—Whitechapel, Shoreditch, Hackney.

PADDINGTON AND BAYSWATER ELECTRIC LIGHT AND POWER SUPPLY—Paddington.

STAMFORD-HILL, TOTTENHAM, AND EDMONTON ELECTRIC LIGHT AND POWER SUPPLY—(1) St. John, Hampstead ; (2) Wandsworth.

WESTMINSTER ELECTRIC SUPPLY CORPORATION, apply for powers to extend the area of supply so as to include the portion of the united parishes of St. Margaret and St. John, Westminster, not already included in their area of supply.

WOOLWICH DISTRICT ELECTRIC LIGHT COMPANY—Woolwich.

### PROVINCES.

| Town, &c. | Name of Applicants. |
|---|---|
| Aberystwyth | Provincial Electric Light and Power Supply. |
| Birmingham | Birmingham Electric Supply Company. |
| Bishop Stortford | Bishop Stortford Electric Light and Steam Laundry Co. |
| *Bolton | The Corporation. |
| Brighton | Brighton and Hove Electric Light Company. |
| Bromley (Kent) | Urban Sanitary Authority. |
| Canterbury | The Corporation. |

| Killarney | The Town Commissioners.<br>C. E. Leahy, Esq. |
| Kingston-on-Thames | The Corporation. |
| *Leamington | The Corporation. |
| Leamington Royal Spa | Midland Electric Light and Power Company. |
| Leeds | National Electric Supply Company.<br>Electric Installation and Maintenance Company.<br>Yorkshire House-to-House Electricity Company. |
| Liverpool (†) | Liverpool Electric Supply Company. |
| Llanelly | The Local Board. |
| Londonderry | The Corporation. |
| Newcastle-on Tyne | Newcastle and District Electric Lighting Company. |
| Newport (Mon.) | The Corporation. |
| Norwich | Norwich Electricity Company. |
| *Paisley | The Corporation. |
| Poole | Brush Electrical Engineering Company. |
| Preston | National Electric Supply Company. |
| Scarborough (‡) | The Corporation. |
| Southend | The Local Board. |
| *Southport | The Corporation. |
| South Shields | The Corporation. |
| *Stockport | The Corporation. |
| *Sunderland | The Corporation. |
| Surbiton | The Improvement Commissioners. |
| Torquay | The Local Board. |
| Toxteth Park | Liverpool Electric Supply Company. |
| Tunbridge Wells | The Corporation. |
| Tynemouth | The Corporation. |
| Weston-super-Mare | The Improvement Commissioners. |
| Weybridge | Laing, Wharton, and Down Construction Syndicate. |
| Weymouth | Weymouth Electricity Supply Company. |
| Whitby | The Local Board. |
| Whitehaven | The Town and Harbour Trustees. |
| Withington | Manchester House-to-House Electricity Company. |

**The following list shows the number of applications which have been served by each of the several Companies and by the Local Authorities :—**

| Name of Applicant. | No. of Applications. |
|---|---|
| Birmingham Electric Supply Company | 1 |
| Bishop Stortford Electric Light and Steam Laundry Company | 1 |
| Brighton and Hove Electric Light Company | 1 |
| Brush Electrical Engineering Company | 4 |
| Camberwell and Islington Electric Light and Power Supply | 2 |
| Electric Installation and Maintenance Company | 1 |
| Exeter Electric Light Company | 1 |
| Ipswich Electricity Supply Company | 1 |
| Laing, Wharton and Down | 2 |
| Laurence, Scott and Co. | 1 |
| Leahy, Mr. C. E. | 1 |
| Liverpool Electric Supply Company | 2 |
| Manchester House-to-House Electricity Company | 1 |
| Midland Electric Light and Power Company | 1 |
| National Electric Supply Company | 2 |
| New Cadogan and Belgrave Electric Supply Company | 1 |
| Newcastle and District Electric Lighting Company | 1 |
| Norwich Electricity Company | 1 |
| Paddington and Bayswater Electric Light and Power Supply | 1 |
| Provincial Electric Light and Power Supply | 1 |
| Stamford Hill, Tottenham, and Edmonton Electric Light and Power Supply | 2 |
| Westminster Electric Supply Corporation | 1 |
| Weymouth Electricity Supply Company | 1 |
| Woolwich District Electric Light Company | 1 |
| Yorkshire House-to-House Electricity Company | 1 |
| | 33 |
| Local Authorities | 37 |
| Total | 70 |

† The Liverpool Electric Lighting Order, 1889, to be amended or revoked.
‡ The Scarborough Electric Lighting Order, 1883, to be amended or repealed.

## ELECTRIC TRACTION NOTICES FOR 1891.

In the following notices of proposed applications to Parliament or the Board of Trade powers to use Electric Traction are expressly sought :—

THE METROPOLIS.

| Applicant. | Powers sought. |
|---|---|
| Central London Railway (Company to be formed). | To construct an underground railway from Shepherd's Bush to the City, and to use electricity as the motive power. |
| City and South London Railway Company. | To extend the existing underground line from King William-street, City, to the northern end of the City-road, Islington. Also to construct a subway for foot-passengers along the proposed route. To use electricity or any other mechanical power (except steam locomotives). |
| South Kensington and Paddington Subway (Company to be formed). | To construct subways from South Kensington to Paddington, to make use of electricity or cable power. |

PROVINCES.

| Applicant. | Powers sought. |
|---|---|
| Birmingham Central Tramways Company. | To make use of electrical, steam, cable, mechanical, or other power. |
| Bolton Corporation. | To make use of animal, steam, electrical or other power. |
| Bristol Tramways and Carriage Company. | To use electrical, cable, or any other power except steam. |
| Burton-on-Trent Tramways (Company to be formed). | To work the tramways for the purposes of traffic of every description or for the purposes of such traffic as may be limited by the Provisional Order by means of locomotive, steam, electric or other engines, or other mechanical, electrical, or other motive power, in addition to or in substitution for animal power, and to hold and acquire patent and other rights or licences to use patent rights in relation to any such locomotive power as aforesaid. |
| Dover and Calais Tubular Railway (Company to be formed). | To construct a tubular railway under the Straits of Dover, to employ as motive power steam, electricity, or other mechanical power. |
| Liverpool Corporation. | To let same on lease or otherwise ; to use steam, electrical, or other mechanical power. |

## NEW COMPANIES OF 1890.

The following are the more important of the new Companies dealing with electricity and engineering which have been registered during the past year :—

| Name of Company. | Capital. |
|---|---|
| Archer Pipe Company | £10,000 |
| Andrews and Preece | 25,000 |
| Amalgamated Electricity Supply Company | 100 |
| Atlas Engine Company | 12,000 |
| Avon Indiarubber Company | 50,000 |
| British Insulated Wire Company | 60,000 |
| Buller's (Limited) | 200,000 |
| British Gas Lighting Improvement Company | 160,000 |
| British Guiana Electric Lighting and Power Company | 10,000 |
| Bishop Stortford Electric Light and Steam Laundry Company | 10,000 |
| Baxter's (Limited) | 20,000 |
| Barry and Cardiff Electric Light and Power Supply Company | 1,000 |
| Bristol Electricity Supply Company | 100 |
| Chagford and Devon Electric Light Company | 2,000 |
| Camberwell and Islington Electric Light and Power Supply Company | 1,000 |
| Canterbury Electricity Supply Company | 100 |
| Cardiff Electricity Supply Company | 100 |
| Column Printing Telegraph Company | 100,000 |
| Combination Telephone and Electrical Engineering Company | 20,000 |
| Commercial Contract Corporation | 3,000 |
| Durand Electric, Petroleum and Gas Engine, and Manufacturing Company | 100,000 |
| Dick, Kerr and Co. | 160,000 |
| District Messenger Service and News Company | 200,000 |
| Devonshire Electric Light and Power Supply Company | 1,000 |
| Donald (John) | 20,000 |
| Electricity Supply Companies' Union | 100 |
| Earthy Metals Company | 2,000 |
| Elmore's French Patent Copper Depositing Company | 200,000 |
| Electrical Inventions Company | 35,000 |
| Elmore's Austro-Hungarian Patent Copper Depositing Company | 200,000 |
| Electro-Metallurgical Company | 2,500 |
| Electro-Chemical Syndicate | 5,000 |
| Electrical Supplies and Fittings Company | £20,000 |
| "Electricity and Electrical Engineering" Newspaper Company | 500 |
| Electrolytic Syndicate | 100,000 |
| Electric Stores | 15,000 |
| East Coast Electric Light and Power Supply Company | 1,000 |
| Electrical Engineering Corporation | 150,000 |
| Electrical Engineering Company of Ireland | 50,000 |
| Electric Meter Company | 50,000 |
| Elmore's Wire Manufacturing Company | 300,020 |
| Egestorff (J. A.) and Co. | 10,000 |
| Electric Welding Company | 460,000 |
| Electric and General Investment Company | 200,000 |
| Edinburgh Electric Supply Corporation | 100,000 |
| Fowler, Lancaster and Co. | 22,000 |
| Fareham Electric Light Company | 5,000 |
| Foreign and Colonial Electrical Power Storage Company | 100,500 |
| Ferranti, S. Z. de | 100,000 |
| Franco-African Lighting Syndicate | 25,000 |
| Freedman Battery Company | 2,000 |
| Foreign Electric Date and Time Stamp Company | 100,000 |
| Friedenthal and Co. | 20,000 |
| General Electric Power and Traction Company | 350,000 |
| Grangemouth Gas Company | 10,000 |
| Grange Syndicate | 2,000 |
| Gordon Electric Traction Syndicate | 2,400 |
| Gordon (J. E. H.) and Co. | 50,000 |
| Glass and Metal Engineering Company | 5,000 |
| Hanley Electricity Supply Company | 100 |
| Heyford Iron Company | 20,000 |
| Holmes and Sons | 14,000 |
| International Okonite Company | 340,000 |
| Indiarubber Estates Company | 235,000 |
| Ipswich Electricity Supply Company | 100 |
| Keys's Electric Company | 15,600 |
| Kent Patent Arc Lamp Company | 100,000 |
| Kaye (Joseph) and Sons | 30,000 |
| Kidderminster Electric Light and Power Supply Company | 1,000 |
| Kidd (James) and Co. | 3,000 |
| Lane-Fox Electrical Company | 100 |
| Loughboro' Electricity Supply Company | 100 |
| Leeds and London Electrical Engineering Company | 100,000 |
| London Metallurgical Company | 15,000 |
| Lactite | 30,000 |
| Mills's Patent Sectional Boiler Company | 100,000 |
| Mulholland, Maugham and Co. | 5,000 |
| Morgan's Automatic Electric Signal System Syndicate | 5,000 |
| Mutual Telephone Company | 100,000 |
| Maclellan, P. and W. | 300,000 |
| Macmahon's Patent Electric Check Company | 50,000 |
| Muntz's Metal Company | 300,000 |
| Manchester Electricity Supply Company | 100 |
| Norwich Electricity Supply Company | 50,000 |
| New Zealand Electrical Syndicate | 30,000 |
| New Cadogan and Belgrave Electric Supply Company | 1,000 |
| Northern Counties Electric Light and Power Supply Company | 1,000 |
| Nonpareil Electric Lighting Syndicate | 6,000 |
| North British Boiler and Machinery Insurance Company | 75,000 |
| Purnell High-Speed Gas Engine and Manufacturing Company | 50,000 |
| Purdon-Walters' Motor Syndicate | 10,000 |
| Poole and White | 20,000 |
| Paddington and Bayswater Electric Light and Power Supply Company | 1,000 |
| Pascoe, Grenfell and Sons | 200,000 |
| Penzance Electricity Supply Company | 100 |
| Provincial Electric Light and Power Supply Company | 1,000 |
| Plenty and Son | 25,000 |
| Practical Electro-Plating and Enamelling Company | 2,000 |
| Ratcliff and Horner | 20,000 |
| Railway Construction and Maintenance Company of Mexico | 100,000 |
| Steam Loop Company | 70,720 |
| Sleeman Controlled Torpedo Syndicate | 12,000 |
| Scott (Ernest) and Mountain | 70,000 |
| Sheffield Telephone Exchange and Electric Light Company | 100,000 |
| Stamford-hill, Tottenham, and Edmonton Electric Light and Power Supply Company | 1,000 |
| Sherrin Electric Power Generator Company | 100,000 |
| Store's Patent Submarine Engineering Company | 6,100 |
| Trent Gas Engine Company | 15,000 |
| Thorneburry Miners' Safety Lamp Company | 50,000 |
| Tubular Frame Waggon Company | 200,000 |
| Thetford Electric Light and Power Company | 5,000 |
| Tylor (J.) and Sons | 100,000 |
| Thomas and Green | 39,000 |
| United Alkali Company | 6,000,000 |
| Universal Electric Light and Power Trust Corporation | 5,000 |
| United Electricity Supply Company | 100 |
| Vaughan-Sherrin Electrical Engineering Company | 25,000 |
| Venezuela Telephone and Electrical Appliances Company | 70,000 |
| Victoria Torpedo Company | 16,000 |
| Weston-super-Mare Electricity Supply Company | 100 |
| Weymouth Electricity Supply Company | 100 |
| Woolwich District Electric Light Company | 10,000 |
| Weymersch Electric Battery Syndicate | 20,000 |
| TOTAL | £13,121,740 |

Digitized by Google

## PUBLIC COMPANIES WOUND UP IN 1890.

Amongst the companies wound up during the past year are the following (those with an asterisk being voluntary windings-up ordered to be continued under the supervision of the Court):—

Australasian Electric Light Power and Storage Company (amalgamated with the Brush Electrical Engineering Company, Limited).
*Automatic Electric Railway Signal Company, Limited.
Blackman Air Propeller Ventilating Company, Limited (re-constructed as the Blackman Ventilating Company, Limited).
*Buckingham Electric Light and Power Supply Company, Limited.
Buller, Jobson and Co., Limited (re-constructed as Bullers, Limited).
Byng Telephone Company, Limited.
Chemical Carbon Company, Limited.
Edmundson (J.) and Co., Limited.
Electric Traction Company, Limited (amalgamated with the General Electric Power and Traction Company, Limited).
Farmer, Robey, Clarke and Co., Limited.
*International Cable Company, Limited.
Kent Patent Arc Lamp Company, Limited.
Lundy Cable Company, Limited.
MacMahon's Electric Automatic Registering Company, Limited.
Manchester Electric Supply Company, Limited.
Maxim-Weston Electric Company, Limited.
Midland Engineering Company, Limited.
Montevidean and Brazilian Telegraph Company, Limited (amalgamated with the Western and Brazilian Telegraph Company, Limited).
Muntz's Metal Company, Limited (re-constructed).
*Mudge Marchant Engine Company, Limited.
Parker's Electric Wire Corporation, Limited.
Patent Electric Fire Lighter Company, Limited.
Railway and Domestic Electric Lighting Company, Limited.
Railway and Electric Appliances Company, Limited (amalgamated with the Electric Construction Corporation).
Schanschieff Electric Light and Power Company, Limited.
Schanschieff Electric Battery Syndicate, Limited.
Sheffield Telephone Exchange and Electric Light Company, Limited (re-constructed).
*Southwark Foundry Company, Limited.
Statter (J. G.) and Co. (amalgamated with the United Electrical Engineering Company as the Electrical Engineering Corporation, Limited).
Submarine Telegraphs Company, Limited (taken over by the Postal Telegraph Department).
Taunton, Delmard, Lane and Co., Limited.
Telpherage Company, Limited (amalgamated with the Electrical Engineering Corporation, Limited).
United Electrical Engineering Company, Limited (amalgamated with J. G. Statter and Co. as the Electrical Engineering Corporation, Limited).
Volta Electrical Company, Limited.
Whitehall Electric Supply Company, Limited (amalgamated with the Metropolitan Electric Supply Company, Limited).
Woodhouse and Rawson Electric Contract and Maintenance Company, Limited.
Woodhouse and Rawson, Limited.

## AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December* 19, 1890.

**"The Henry."**—The regular monthly meeting of the Institute of Electrical Engineers, December 16th, brought out two very interesting Papers. One of them was on inductance and its proposed unit, the henry, by Mr. A. E. Kennelly, and dealt with both the relations of the henry to other units and to the values met in practice among familiar instruments. The Paper contained a large amount of new and important experimental work, and dealt directly with the question of the proper magnitude for this practical unit. A committee that had previously been appointed by the Institute to determine the most practical value for the henry reported in favour of making this unit equal to one earth quadrant, on the ground that although the small numerical values met with in ordinary practice make so large a unit inconvenient, as it involves many small fractions, nevertheless it would not be advisable to break in on the symmetry of the system of practical units that we already have by adopting a sub-multiple of the earth quadrant for the henry. The new name shows signs of rapidly making its way into general use in this country.

**The Gramophone.**—The other Paper of the evening was by Mr. Emile Berliner on the gramophone. Mr. Berliner gave a full account of the principles and general operation of the gramophone, and illustrated it both by etching the records and reproducing a large variety of musical selections through the instrument. The process of making the records, which is a very interesting one, consists of allowing the tracing point of the diaphragm to form a spiral on a rotating zinc covered with an almost infinitesimally thin layer of wax. The vibrations of the voice are impressed on the wax cutting it through to the zinc in sinusoidal curves. The plate is then etched with chromic acid, so that the record is a permanent one. The reproductions of music as given by the instrument were remarkably diversified and distinct; those heard at the meeting did not, however, compare favourable with the best performances of the phonograph or the micrographophone, although the instrument, it should be said, is a much simpler one, and was turned by hand instead of being driven by a motor.

**The Edison Company.**—The Edison Company has been cutting prices left and right recently, presumably with the intention of starving out small competitors. The drop in prices has been so great as to cause very general comment, and it must result in making the Edison Company very formidable as a competitor, although it will presumably cut down profits. A 2 per cent. quarterly dividend was declared the other day, but the new schedule has not been long enough in operation to show marked effect upon the dividends, either in one direction or the other. It is not improbable that the Company may increase its capital stock ere long.

**The Thomson-Houston Company.**—The Thomson-Houston Company is bestirring itself. Its railway department has been recently put in charge of Mr. O. T. Crosby, well-known as one of the leading authorities on electric traction, and intimately identified with the development of the art when in the hands of the old Sprague Company. As the West End Railway Company of Boston is about to erect an electric elevated road in which the Thomson-Houston system is to be used, the acquisition of Mr. Crosby is a specially valuable one.

## SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

COPENHAGEN, *December* 26, 1890.

The Christiania Telephone Company's new central exchange is now completed. The company has now about 2,500 subscribers. In the year 1884, when the Company was formed by the amalgamation of two older companies, the subscribers numbered 1,400. The present station is able to accommodate twice the present number of subscribers, viz., 5,000. The present traffic amounts to about 13,000 conversations per day. There are thirteen tables, each with 200 numbers, and each attended by two female clerks, and the new station is very well appointed in every respect.

The Stockholm General Telephone Company continues to do all it can for the purpose of accommodating its subscribers. The recent severe white frost has proved very troublesome for the Company, and has interfered materially with their business. The constantly increasing weight of the hoar frost has broken a number of wires, which has, of course, led to further complications. Great efforts have been made to counteract the frost, and the Company has tried to melt it by sending currents through the wires from the electric light installation. The remedy, however, proved worse than the disease.

The new Swedish ironclad "Göta" has had electric light installed on rather an extensive scale. The installation comprises 159 incandescent lamps of 16 candle-power, and four reflectors of about 50,000 candle-power each. The dynamos are coupled direct to the engines, the speed being about 400 revolutions. The engines are supplied from the Government workshops, the electric installation by the firm of Luth and Rosen. The central electric station at Halmstad, Sweden, has been recently completed, the installation having been carried out by the L. M. Ericsson's Engineering Company, Stockholm. It comprises both street and house lighting, the former taking 50 1,200-candle-power arcs and 25 25-candle-power incandescents. The house lighting amounts to some 700 16-candle-power incandescents. The street lighting is divided into two sections which can be handled independently of each other. One section is turned out at 11 p.m., and the other does the lighting till daybreak.

The Danish State Telegraphs show, as usual, a loss on last year's working; this has been the case since 1876, and the loss on the

Digitized by Google

working amounts in the aggregate to 1,239,867kr. (£62,000). The number of telegrams amounted to 1,494,622, which is about 30,000 messages less than the previous year. During the year the length of line was increased by 13, and the length of wire by 52 geographical miles, the total length of wire now being 1,629 geographical miles. There are 162 State telegraph stations, and 202 railway telegraph stations; 57 telephone stations have direct connection with the State Telegraphs. The Danish State Telegraphs have a total of 496 instruments, of which 7 are Wheatstones, 384 ordinary Morse instruments, and 105 telephone instruments. The revenue for telegrams amounted to 720,076kr. (£36,000), as far as the State was concerned. The number of telegrams sent averages 36 per 100 inhabitants per annum.

The new cable between Newcastle and Gothenburg further enhances the importance of this latter town as a cable station. The new cable is the fourth which connects Sweden with the East of Europe, there being now three between Sweden and England, and one between Sweden and Denmark, for France, Spain, Portugal, &c.

## CORRESPONDENCE.

### THE DETERMINATION OF INDUCTANCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of November 21, 1890, you reproduced an abstract of my article on the determination of inductive resistances and coefficients of self-induction of measuring instruments, which appeared a short time ago in the *Electrical Engineer* of New York, and accompanied it with a few editorial remarks. In regard to these I would like to give some explanations, which I hope will make the matter clear.

I have found this method especially satisfactory for determining the coefficient of self-induction of measuring instruments, and cannot consider those five observed quantities in equation (13) as a drawback, because, as you will see from the fundamental equations (10) and (11), in reality only two alternate-current readings are needed, and the other terms are resistances, which even in a factory generally can be determined with a very high degree of exactness. That, nevertheless, I prefer a specialised form of equation (13) for practical use in determining the self-induction of *ammeters* is justified by the fact that such low resistances as occur in ammeters are generally more exactly measured by current-strength and potential than by Wheatstone's bridge.

The great number of decimals given in the application of the method ought not to astonish you either. I gave these figures as it is usual in exact sciences, for instance, in astronomy, that is, "the result of calculation is given with one decimal more as can be relied upon." Those figures are not at all single readings, as it may seem at first, but are the average values each of a set of about 10 readings. Therefore a greater exactness than is usual with a single instrument-reading is not at all surprising.

As you will see, nowhere the current, but everywhere the ratio of two currents enters the equations, and these, therefore, hold good even for a proportional and simultaneous increase or decrease of one pair of current-readings. Therefore different values: $c_1', c_1'', c_1''' \ldots c_1^x$ were observed, and also the corresponding values: $c_2', c_2'', c_2''' \ldots c_2^x$, and then all these values were reduced to the average value: $c_1 = \text{av.}\ \{c_1', c_1'' \ldots c_1^x\}$

$$c_2 = \text{av.} \left\{ c_2' \frac{c_1}{c_1'},\ c_2'' \frac{c_1}{c_1''} \ldots c_2^x \frac{c_1}{c_1^x} \right\}.$$

It is obvious that in this way a rather high accuracy can be reached even with ordinary instruments, if it is necessary, as it was in my case.

The instrument which I used for measuring inductive resistances was not a Cardew voltmeter, but an electro-dynamometer-voltmeter, with a shifting of phase of 5deg. for 100 complete periods per second. If a Cardew voltmeter is used for the determination of inductance, the ammeter will more conveniently be arranged in series with inductive resistance and voltmeter, these being connected in parallel. Then the ammeter measures the resulting current of voltmeter and inductance current, that is, the third side in a triangle, the one side of which is the voltmeter current, and the other side the current in the inductance, and the angle between both latter sides the shifting of phase by the inductance, and therefore the coefficient of self-induction of the ammeter does not enter the equations, which assume a little different form: always the coefficient of self-induction of either the ammeter—when the voltmeter is "in long shunt" or of voltmeter when being "in short shunt"—enters the result, and, if the self-induction of the voltmeter = 0, we, therefore, will prefer the latter arrangement.—Yours, &c., CHAS STEINMETZ.

Yonkers, New York, December 12, 1890.

[When mean readings are given, it is desirable to state the average divergence of the single observations from the mean, as a comparison of the two always forms an excellent test of the practical value of the method.—ED. *E.*]

### PERMANENT MAGNET VOLTMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In an editorial paragraph which appeared in the issue of *The Electrician* of the 5th inst., you make a statement concerning the temperature error of the Weston voltmeter, of the permanent magnet type, that requires correction. The temperature compensating device, attributed to Mr. Weston, and described in your notes, is not used in connection with the permanent magnet type of voltmeter. While applicable to many instruments, it was especially designed for use in connection with a portable electro dynamometer for measuring alternating current potentials. In order to keep the current in this instrument low, and to obtain the necessary couple for a full scale (6in.) deflection of the index, with a given potential difference, it was deemed expedient to wind the coils with copper wire. This, of course, necessitates a correction of the instrument readings amounting to 1 per cent. for each five degrees of temperature (Fahrenheit) variation from the normal. While the compensating device may be neither novel or positively accurate, it is in this particular instrument more feasible and far less costly than the differential winding of the coils with conductors having different temperature coefficients mentioned by you.

The Weston permanent magnet voltmeter is wound with German silver wire, having a temperature coefficient of ·02 per cent. per degree Fahrenheit. As the average resistance of these instruments exceeds 100 ohms per volt, it is evident that the temperature error cannot be large, as you state, but instead it is so small as to require no correction, except in very accurate test work. The actual error for a variation of external temperature of 35 degrees above or 35 degrees below 70 degrees Fahrenheit is a small fraction of 1 per cent. The instrument may, therefore, be left continuously in circuit, and to this end, when contact keys are provided, they are made with a locking attachment, so arranged that the circuit may be maintained intact by a quarter turn of the key.

In view of the general distrust of permanent magnet instruments, it may not be amiss to add that the writer has used one of these instruments daily in calibration work for nearly two years, and that, although checked at frequent intervals with a series of Clark cells (zero method), no change has yet been observed amounting to one-tenth of 1 per cent. It is a fact also that of the very large number of these instruments used in commercial work, when they are exposed to the action of powerful magnetic fields, but a very few have changed, and of these few the majority have shown an increase in the strength of the magnets instead of the expected decrease, the maximum change, however, seldom exceeding two per cent.

Results like the above are substantial evidence of a reformation of the past character of instruments of the permanent magnet type, and certainly warrant their re-adoption and continued use for all direct-current measurements.—Yours, &c.,

The Electric Club, New York, EDWARD F. COLBY.
Dec. 19, 1890.

[It would not appear that for ordinary work a thermometer need be used, when the temperature coefficient is ·02 per cent. per degree Fah. But for accurate testing, of course, thermometers are always used, and have been used for years; such thermometers may be easily read to ·025°C. We understand

that the compensation winding to which we alluded, and which we much prefer to the device referred to by our correspondent, costs about 10s. extra.—Ed. *E.*]

## "SHAKING THE FOUNDATION OF SCIENCE."

TO THE EDITOR OF THE ELECTRICIAN.

Sir: My attention has been drawn to the article in *Nature* under the above title, and, as it presents to your readers the proposed South Kensington and Paddington Subway, in an aspect which the writer erroneously describes as "the hosts of Mammon threatening the domains of science," I feel sanguine that a scientific journal such as yours will be even more than ordinarily desirous to have the correct view set before them.

The writer appears to ignore the fact that the rectangular area bounded by Kensington, Cromwell, Exhibition, and Prince Albert (now Queen's-gate) roads forms part of the estate purchased out of the surplus funds of the Great Exhibition of 1851, and vested in a body of Commissioners by Royal Charter; and that this land was originally destined, to use the words of the late Prince Consort, "at no distant day to form the inner court of a vast quadrangle of public buildings rendered easily accessible by the broad roads which surround them, buildings where Science and Art may find space for development, with the air and light which are elsewhere well nigh banished from this overgrown Metropolis." The site of the Exhibition of 1862, and of the buildings of the South Kensington and Science and Art Departments, originally formed part of that estate. When the Royal Albert Hall was first projected, a pneumatic railway from it to the South Kensington Station, *viâ* Exhibition road, formed part of the original scheme, which was promoted by the Commissioners who own the estate, and the paramount necessity of such a means of communication has never been lost sight of. When the existing subway was constructed in 1885 its continuance as far as the Albert Hall was a recognised part of the project, and the route alongside of the Eastern Arcades was then decided upon by the Commissioners. When the District Railway Company obtained their Act of Parliament for the subway its use with traction was sanctioned.

The proposal now before Parliament is for absolutely no more and no less, so far as the estate of the Commissioners of 1851 is concerned, than the completion of that subway, with nearly its present form and dimensions, and with almost the same powers to use it in the same way. All attempts hitherto made to complete the work as far as the Albert Hall have failed, and the existing incomplete portion of the subway is practically closed, and is a dead loss financially.

At last a practical solution of the difficulty has been found, with the additional advantage that, besides the means of covered access being afforded from South Kensington Station through the length of the estate, easy and rapid communication will also be afforded to hundreds of thousands of persons living to the north of Hyde Park to visit and use all the great institutions collected at South Kensington, to which covered access will thus further be secured from all parts of the Metropolis.

In his eagerness to prove that the present means of access are all that can be desired, your contributor refers to the congregations of visitors attracted by former Exhibitions. The steady annual decline in the records of the numbers of visitors to the permanent institutions is not the only evidence which utterly refutes such a misleading line of argument.

I do not dispute for one moment that Urania must have her quiet retreats, secluded from the movements and throng of men and vehicles, and it is hardly surprising that, as your contributor states, the repose she loves cannot even now be found at South Kensington. But it is pure affectation to contend that the interests of the highest scientific education for the many will suffer because laboratories and observatories for original research used for the instruction of a very few experts may have to find a home elsewhere. If the vibration caused by omnibuses by day and market carts by night, passing at each end of Exhibition-road in the Kensington and Cromwell-roads (to say nothing of "small and earlies") are found already to affect the ultra-sensitive nerves of Urania, the question may be asked why the Professors continue to countenance the expenditure of the "vast sums" mentioned by your contributor, and also if it is right that any more public money should be allowed to be spent in a way which experience has already shown to be injudicious.

It appears, therefore, evident that the degree to which the traffic in the proposed subway might augment this inconvenience does not affect the true merits of the case as set up by your contributor.—Yours, &c.,

C. E. Webber, Major-General.

## ELECTRICAL TREATMENT OF SEWAGE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have read with interest the criticisms on Webster's System of Sewage Treatment; *first*, because I am intimately connected with the Electrical Company formed for the purpose of verifying and demonstrating the practical application of the process, and, *secondly*, it was I who, owing to Mr. Webster's ill-health, was asked at the eleventh hour, and who consented, to read Mr. Webster's paper, which has given rise to the present discussion.

As stated by Mr. Webster in his paper, a searching investigation has been made this year by the Corporation of Salford, on a working scale, as to the merits of various processes of sewage treatment, including the Electrical. I personally followed the electrical trials throughout, which, as well as the other processes, were independently controlled by several engineers and chemists representing the Salford authorities. Until the joint report of these gentlemen is issued it is, in my opinion, premature to reply to the various points raised, as such report, being from independent sources, will necessarily carry more weight than anything I can say.

I may, however, state it is the intention of myself, and of all those directly interested in the electrical process, that there should be no concealment of any fact in connection with it. The original reports of chemists and others who have examined the process from the date of practical working on London sewage and up to the present time will be open to inspection by all scientific men, so that those capable of reading between the lines may see that everything is fair and above board. I personally undertake that the fullest details in possession of the company, both as to chemical results, cost, and practical every-day working, shall at the earliest possible moment be put at the disposal of the scientific public: the fullest criticism will be welcome.

I think there will be no difficulty in satisfying your correspondent, Mr. Ed. C. de Segundo, on any of the questions raised by him, even that of simplicity. He will, I hope, pardon me for saying that he has gone outside the heading of his letter, "*Electrical* Treatment of Sewage," to give the palm to the "International" Company. Doubtless the "International" and other companies will, as well as the Electrical, eagerly seize the opportunity of submitting with the Salford report the fullest details of practical working wherever the respective systems may have been tested.—I am, &c., F. G. Worth.

Whitehall Club, Parliament-street, S.W.,
December 23, 1890.

## COMPOUND DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue of this week, under the head of Notes, you remark with regard to the City and South London Railway that owing to the dynamos being used as simple shunt machines, variations in the main current produce an awkward variation in the light in the carriages. May I be allowed to draw attention to a point which I have sometimes found occasion considerable annoyance to users of large compound machines; it is the excessive sluggishness of the compounding which one gets when large masses of iron are employed in the magnets, due to Foucault currents and self-induction. In machines with magnets of about three square feet in section the series turns sometimes require as much as half a minute to complete their work after a considerable variation in the main current. It remains to be seen whether this effect will cause trouble in the case of

Digitized by Google

the City and South London Railway, when the series turns on the magnets of the dynamos are used. I enclose a few curves which may be of interest as helping to illustrate the lag of induction through the armature of a dynamo behind the exciting current in the field circuit. The experiments refer to a compound dynamo with magnets 20in. by 8in. in section (unfortunately somewhat small). Figs. 1 and 2 illustrate

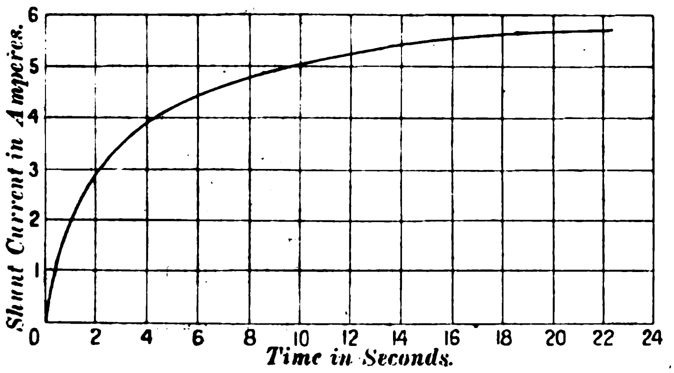

Fig. 1.

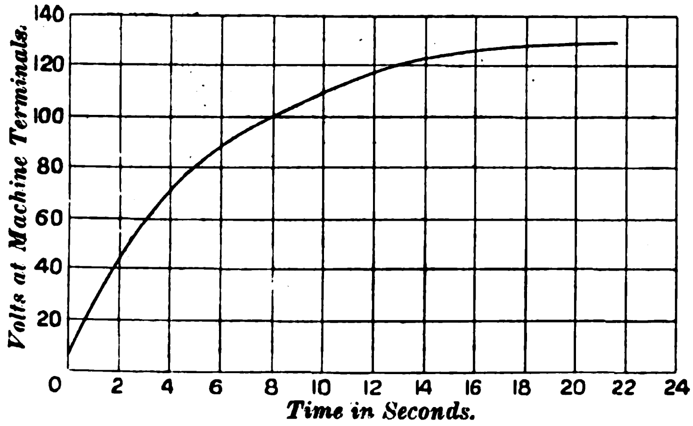

Fig. 2.

the rise of current in the exciting circuit, and the rise of potential difference at the terminals of the machine respectively, when running on open circuit at constant speed, the shunt circuit then being suddenly switched on to mains at a potential difference of 130 volts. A comparison of the ordinates of these two curves at the same instant gives us a third curve which will

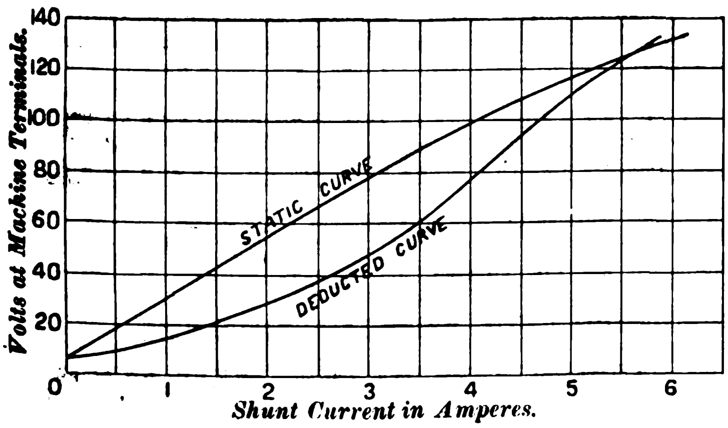

Fig. 3.

represent to a certain scale the variation of the induction through the armature, with the exciting current producing it.

In Fig. 3 this curve, with varying current, is compared with a similar one taken with a steady magnetising current, a considerable interval being given between each reading to allow the magnetism to settle.

The voltmeter used was one made by Messrs. Siemens, known as Type No. 3, having a resistance of 1878·12ω at 18° C., and an ordinary electro-dynamometer was used in the shunt circuit to measure the current, both instruments being zero instruments. Curves like those given may readily be obtained by means of a good stop-watch and zero instruments by noting the time that elapses between the closing of the switch and the crossing of the zero by the index, a certain torque having been previously placed upon the torsion head, after which the circuit is broken, the torsion on the heads of the instruments varied, and the operation repeated. In the case of large magnets a short-circuiting switch should be provided to avoid the stress which would otherwise be placed upon the insulation of the shunt coils at the moment of breaking the circuit between each reading. The value of L for the voltmeter was measured with various currents by my alt-current method, published in *The Electrician*, No. 632, Vol. XXV., and checked by Lord Rayleigh's bridge test. The average value was found to be 1·05 henrys, corresponding to a time constant of ·00053 secs., the correction for which, upon the potential difference curve it was thought might be neglected.—Yours truly, William Brew.

British Museum, Electric Light Department,
December 20, 1890.

## DRUM WINDING.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I notice in your issue of December 19, in the article by Mr. F. M. Weymouth on armature windings, that the spiral end winding is attributed to a person in the employ of Messrs. Latimer, Clark, Muirhead and Co.

This system of end winding was claimed and described in my patent, A.D. 1884, November 7th, No. 14,723. It has been almost exclusively used for my Turbo-electric generators, of which some 5,000 horse-power are now in use; and, so far as I know, has not been described or used elsewhere.

I have no doubt that you will be pleased to have this small correction made. Thanking you in anticipation.—Yours, &c.,

Charles A. Parsons.

Heaton Works, Newcastle-on-Tyne, December 26, 1890.

[We may mention that a Mr. A. J. White, of Newcastle, wrote us a few days ago stating that he was the young *employé* alluded to by Mr. Weymouth. We should be glad to hear from him as to the date of his invention.—Ed. *E.*]

## TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

Plant for Sale.—We call our readers' attention to the particulars of several lots of first-class electrical plant, &c., for sale by Messrs. Wheatley Kirk, Price and Goulty, and others.

Great Fire in the City.—Amongst the firms whose premises have been seriously injured by the great fire which occurred on Tuesday last in Queen Victoria-street, E.C., were Messrs. Davey, Paxman, and Co., and the Rossendale Belting Company, but we understand that in neither case will business be interfered with.

Church Lighting. — Emmanuel Church, Maida-hill, is being wired for the electric light by Messrs. Laing, Wharton, and Down, under the direction of Mr. A. E. Gosset-Tanner.

Messrs. Arthur B. Gill and Co.—We are in receipt of this firm's price list of shades, globes, and reflectors for incandescence lamps.

Paterson and Cooper.—During the whole of the year, Messrs. Paterson and Cooper have been busy, and have carried out a large number of ship lighting installations. A larger number of dynamos has been turned out than in any previous year, and the sizes have all round averaged larger. In the instrument and fittings department trade has also been good, a new alternating current arc lamp has been designed. The prospects for the new year are very encouraging.

Messrs. J. H. Holmes and Company.—This firm state that they have been kept extremely busy throughout the year, their output

in dynamos being about double that of any previous year. The demand for their machines has increased so rapidly that, although the works have been doubled in size during the year, the firm have been obliged to decline some urgent orders. Messrs. Holmes have also completed 66 installations of electric light in mills, factories, residences, steamships, &c.

Messrs. Drake and Gorham.—The increase of business during the past year has been so marked that Messrs. Drake and Gorham state they have been compelled to make constant additions to their staff, and to extend their offices and stores. The number of installations carried out has exceeded the record of any previous year. Amongst the more important installations are the new police buildings and the exhibition at Madame Tussauds. During the year the Cardew Earthing Device has been adapted by the London Electric Supply Company, the Newcastle Company, and Metropolitan Electric Supply Company. Messrs Drake and Gorham have made arrangements for driving the printing machinery at New Scotland-yard by means of electricity.

The Electrical Accessories Company.—This Company has been during the past year engaged in completing its standard patterns of switches, &c., in which departments they record a busy trade. We understand that further capital will shortly be raised, and that it is contemplated taking larger manufacturing premises.

Poole and White's Logarithm Table.—It is an indication of the scientific character of the electrical trade, that one of the leading firms for electrical supplies should consider that a neatly-bound table of logarithms is a suitable article for issue at Christmas. The table is mounted on strong linen, and is about 12in. by 8in. Above it is a good list of constants and coefficients, and in a lower corner a sheet of celluloid, on which pencil calculations may be made and effaced. The logarithms are four figure, with differences, arranged in accordance with Mr. Bottomley's well-known plan. The table, which is excellently printed and got up and folds in a leather binding, will be appreciated by all engineers, whether electrical or using slide rules or otherwise.

Postal Reductions and Extensions.—The postage to be prepaid on letters to India and the British Colonies in Asia, Australasia, South and West Africa, and the West Indies is now at the rate of 2½d. per ½oz., instead of 5d. as formerly. The reduced postage is applicable to all routes, except in the case of the Cape and Natal. The rate for postcards to Australasia, New Zealand, Fiji, and British New Guinea is 2d. British North Borneo has now entered the Postal Union. The letter rate will be 2½d. per ½oz. ; postcards, *viâ* Brindisi, 2d., and by French packet, 1½d. ; newspapers, 1½d. per 4oz. Postcards may now be sent to Natal either by the sea route or *viâ* Lisbon, the postage being 1½d. per card by the sea route and 2d. *viâ* Lisbon.

## BOOKS, &c., RECEIVED.

"The School of Mines Quarterly." No. 1, Vol. XII. (Columbia College, New York.)

"Fortschritte der Elektrotecknik." By Dr. Karl Strecker. (Berlin : Julius Springer.)

## PATENT RECORD.

### APPLICATIONS FOR PATENTS.

December 12, 1890.

20,289. T. D. Bottome, Hoosick, New York. Improvements in and relating to the manufacture of insulating compositions for electrical uses.

20,294. M. Sutherland and A. J. McGeoch. London. Improvements in junctions for electric conductors.

20,307. C. G. Dahlgren and J. H. Svensson. London. Improvements in electrical switches.

20,321. O. H. Stovell. London. Improvements in the lighting of tables and the like by electricity.

20,329. A. B. Woakes. London. Improvements in and relating to transformers for electric currents.

20,332. S. Hargreaves and R. J. Bott. London. A combined arrangement of switches and gearing for controlling any number of dynamos and engines from one or more fixed positions.

### SPECIFICATIONS PUBLISHED.

1889.

13,389. Harper. Electro-magnets for arc lamps. (Price 8d.)

19,450. Leblanc. Electro motor, (Price 8d.)

20,022. Wilson. Electric switch. (Price 8d.)

1890.

1,026. Boult. Automatic accumulator switches. (Price 8d.)

1,302. Trotter. Facilitating calculations relating to supply of electrical energy. (Price 8d.)

1,629. Boult (Wm. Giovanni). Electric accumulators.

7,094. Upward. Applying electrical energy for advertisements. (Price 4d.)

9,956. Kennedy. Heating by electricity. (Price 8d.)

11,480. Thomson. Dynamo electric machines and electro motors. (Price 8d.)

12,221. Lake, (Weston). Measuring electrical energy. (Price 6d.)

14,548. Wiegand. Telegraphing and telephoning. (Price 8d.)

15,741. Douse. Electric fire indicator. (Price 8d.)

17,327. Miller. Electric meter. (Price 6d.)

## COMPANIES' MEETINGS.

### Elmore's Foreign and Colonial Patent Copper Depositing Company (Limited).

The first annual general meeting of this Company was held on Monday, at the offices, 64, Cannon-street, under the presidency of Sir John Morris, K.C.S.I.

The SECRETARY (Mr. J. Shurmer) having read the notice convening the meeting,

The CHAIRMAN said that they were met to transact the ordinary business of the Company, which, on this occasion, was merely to approve and pass the accounts and to re-elect the retiring directors and auditors.

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.
Hard Drawn High Conductivity Copper Wire.
ROLLED AND DRAWN PHOSPHOR BRONZE.
PHOSPHOR BRONZE — VULCAN — PHOSPHOR — DURO METAL
PHOSPHOR BRONZE BEARINGS, BUSHES, AND OTHER PARTS OF ELECTRICAL MACHINERY
SOLE PROPRIETORS of the British, Indian and Colonial Patents,
THE PHOSPHOR BRONZE COMPANY (Limited),
87, Sumner Street, Southwark, London, S.E.
WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

Digitized by Google

They had not issued any report; because, in the period embraced in the accounts, there had been little or no business done. The purpose for which this Company was formed was to dispose of their foreign patents. They had nothing to do with the working of the process. They had only to sell their patents to foreign countries. Therefore, in the period covered by the accounts, namely, from June 6, 1889, to March 31, 1890, nothing of importance had been done. He did not mean to say that they had been idle. Negotiations were carried on with several parties for the sale of the patents, but in consequence of the undeveloped state of the process, they could get no specific offers. They would recollect that he told them at the statutory meeting that they were prepared to enter into negotiations, but that they wanted specific offers which, when they came to negotiate, they found they could not get on account of their process not being sufficiently proved, and also because they were not ready to let people go over the English Company's works—which the Directors did not think were then sufficiently advanced to warrant their doing so. Such negotiations as were carried on up to March 31st accordingly fell through. There were, therefore, no sales made, a circumstance which would explain why there was little or nothing on the credit side of the accounts. They had simply an amount of interest, and a small amount of transfer fees. On the expenditure side there were the ordinary items of office expenses, salaries, wages, and Directors' fees. The only two large sums which he need notice were those of salaries and Directors, fees, which were strictly in accordance with the Articles of Association. As for the patent charges, they were fixed, and could not be modified. He might mention that the accounts, if passed now, would be again brought up before them in January, and would be embodied with those which they proposed to submit, taking them up to the end of the year. He concluded by moving a resolution approving of the accounts as submitted.

Mr. JOHN MACFARLAN seconded the motion, which was passed unanimously.

The retiring Directors, Messrs. E. J. Carson, J. J. Atkinson, and John T. Cooper were afterwards re-elected, as were also the auditors, Messrs. Pixley and Co.

The CHAIRMAN then proposed a resolution altering the date to which the statement of accounts should be made up, namely, to December 31. He explained that the reason for this was that they had carried through some important sales of the patents of the Company, and as they all knew they had paid an interim dividend of £4 per share on the priorities, they were, therefore, naturally anxious to lay before the shareholders a full account of what they had been doing during the nine months which had relapsed since March 31st.

Mr. EWEN seconded the resolution, which was agreed to *nem. con.*, and the proceedings terminated with a vote of thanks to the Chairman and Directors and Staff.

## NEW COMPANIES REGISTERED.

**JOHN DONALD (LIMITED).**—Registered in Scotland by Paul and Macfarlan, writers, Glasgow. This Company has a capital of £20,000 in £10 shares. Object: to carry on in the United Kingdom and elsewhere the business of iron merchants, engineers, boiler-makers, shipbuilders, ironfounders, and general contractors, and any other trade and business arising out of or incidental thereto.

**THE SAMPAN PATENT RAILWAY SLEEPER AND STEEL PLANT SYNDICATE (LIMITED).**—Registered by R. Jordan, 120, Chancery-lane, with a capital of £10,000 in £50 shares. Object: to carry on the business of mechanical engineers, manufacturing machine and engine tool makers, iron, brass, and metal founders, &c., &c.

**NEW ZEALAND ELECTRICAL SYNDICATE (LIMITED).**—Registered by Reyroux, Phillips and Golding, 99, Cannon-street, E.C., with a capital of £30,000 in £10 shares. Object: to acquire charters, concessions, privileges and other grants for the manufacture and employment of electric lighting, &c., in New Zealand, Victoria, New South Wales, North, South, or Western Australia, Tasmania, New Guinea, and the Fiji Islands, and particularly to acquire the central stations for the supply of electricity erected by the Gulcher (New) Electric Light and Power Company (Limited), in the city of Wellington, New Zealand. The first subscribers are:—

| | Shares. |
|---|---|
| D. de Castro, 6, New-square, Lincoln's-inn | 1 |
| W. Turnbull, Mount Hanley, Sydenham | 1 |
| R. Pryor, 79, Gracechurch-street, E.C. | 1 |
| M. S. Vanderbyl, 187, Queen's-gate, S.W. | 1 |
| H. Grëwing, 14, Austinfriars | 1 |
| J. Alexander, 3, Great Winchester-street | 1 |
| W. Farmer, 48, Aldermanbury | 1 |

There shall not be less than three nor more than seven Directors. The first are D. de Castro, H. Grëwing, M. S. Vanderbyl, and J. E. Williams. Qualification and remuneration not specified.

## CITY NOTES, &c.

**BRAZILIAN SUBMARINE TELEGRAPH COMPANY.**—The receipts of this Company for the week ending December 26th amounted to £4,441.

**W. T. HENLEY'S TELEGRAPH WORKS COMPANY (LIMITED).**—At the meeting of this Company, which was held on the 19th ult., the Chairman, in the course of his remarks, stated that the business for the year 1889 had been far more successful than any previous year in the history of the Company, and that the present year (1890) showed a very considerable improvement upon 1889. The business carried out successfully included the manufacture and laying of the Halifax and Bermudas cables, 850 nautical miles, by the ss. "Westmeath," and the construction of over 1,000 miles of submarine telegraph cable to be laid in the West Indies, and on the coast of South America, news having been just received of the successful completion of the laying of these cables by the ss. "Westmeath." The machinery for the manufacture of the miscellaneous products of the Company, which included all descriptions of wires and cables for electric lighting, telephony, &c., had been fully employed.

**SPIEL'S PETROLEUM ENGINE COMPANY (LIMITED).**—At the annual meeting held on Wednesday, the Chairman, Mr. D. W. Forbes, said that the Directors were in negotiation with a firm of very high standing for the manufacture of their engines in the place of the late Mr. Clarke, and if they were successful in treating with them, there was no doubt of the Company becoming very prosperous. The Directors' report and accounts were adopted.

**STOCK EXCHANGE.**—Applications have been made to the committee to appoint a special settling day in the shares and debentures of the Venezuela Telephone and Electrical Appliances Company (Limited), and to allow the shares of Elmore's French Patent Copper-Depositing Company (Limited) to be quoted in the Official List.

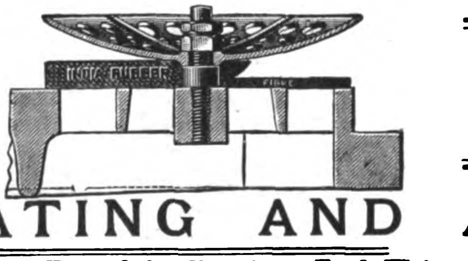
**WESTERN AND BRAZILIAN TELEGRAPH COMPANY.**—The traffic receipts of this Company for the week ending December 26, 1890, after deducting the "fifth" of the gross receipts payable to the London Platino-Brasilian Telegraph Company (Limited), were £3,453.

**THE WESTINGHOUSE ELECTRIC COMPANY.**—A special despatch from Pittsburg of December 10th says:—"The committee of local bankers recently appointed to investigate the financial standing of the Westinghouse Electric Company finished its labours to-day. Its report is understood to be favourable. The committee determined that the electric company stocks are worth over $25 per share, and decided to advance the $500,000 recently requested by Mr. Westinghouse, on condition that the parties making the loan have the privilege of naming the general manager for the company.

**WHITE'S ASBESTOS (LIMITED).**—A meeting of this Company was held on Tuesday at Winchester House, Mr. J. H. Hamilton presiding. After a long discussion upon the unsatisfactory condition of the Company, a committee of shareholders was appointed to confer with the Directors, and investigate the affairs of the Company.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.
"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 660.—Vol. XXVI. FRIDAY, JANUARY 9, 1891. Price Fourpence.

## NOTES.

Under the Public Health Acts (Amendment) Act of 1890 an Urban Authority may from time to time make bye-laws for the prevention of danger or obstruction to the public by overhead wires. By such bye-laws provisions may be made for the inspection and examination of posts, wires, &c., by the Urban Authority, who may prohibit any work that is dangerous or causes obstruction to the public. Such bye-laws have to be submitted to and confirmed by the Board of Trade, who may modify or disallow them. So far as we are aware no such bye-laws have yet been made since those of Bradford, and the proposed Liverpool rules are of a far more comprehensive nature. The overhead wire rules issued by the Board of Trade two years ago professed to be "for the protection of the public safety and of the electric lines and works of the Postmaster-General." These were subsequently incorporated in the second set of rules (*Electrician*, Vol. XXV., p. 466), which were issued in August last, "for securing the safety of the public, and for ensuring a proper and sufficient supply of electrical energy." The bye-laws which the Urban Authorities are invited to make are not intended to deal with the efficiency of supply, with the maintenance of standard volts, the detection and removal of leaks, or indeed with anything but overhead conductors. The need of a double set of regulations is not, therefore, very apparent. The Board of Trade rules are excellently drawn up, save in one or two points, to which we have on former occasions alluded, and it would seem that it is only under peculiar conditions arising out of local circumstances that there can be any occasion for the Urban Authorities to trouble themselves about the matter. The paternal work which the Board of Trade has executed should generally be sufficient, and unless good cause is shown, any additional rules are likely to produce more harm than good.

It is probable that the proposed bye-laws, if ever they are made, will affect telephone and telegraph wires much more than conductors for electric light. The conditions under which the latter may be erected are already so onerous that a very slight addition would prohibit them. The Board of Trade rules, however, being under the Electric Lighting Acts, could not deal in any way with telephone wires, and it is possible that this may be a device for controlling them. That they need some control is obvious, and now that a large number of private wires may be expected, especially in the Provinces, it is surprising that the Board of Trade have not themselves the power to issue a set of regulations.

We have received from Messrs. Knight and Co, a set of model bye-laws, which are evidently based upon the Board of Trade rules. There is not much to be said about them except that they suggest that each wire must be "shackled off and securely attached to the insulators at the supports," and that every support, if metal, must be efficiently connected with the earth, and if of wood, or other non-conducting material, to be protected from lightning by a proper and efficient lightning conductor.

We had hoped that the experience gained by the first few days' working would have resulted in the disappearance of the many small, but irritating, defects which were noticeable at the opening of the City and South London Railway. If we may judge, however, by a lengthy letter in an evening contemporary, there is still much room for complaint. The trains, it seems, are terribly overcrowded during the busy hours, the ventilation of the cars is indifferent, the lighting is "practically a nuisance," the lifts work slowly and irregularly, and the staff at the turnstiles is inadequate. It seems to us that in spite of encouraging traffic returns, the Directors would do well to have these defects remedied without further delay. The City and South London Railway must not only do as well as other suburban lines, it must do a great deal better. It is, moreover, to be borne in mind that novelty is only a temporary attraction, and that comfort and regularity will alone secure permanent patronage.

The shareholders of the Company are certainly to be congratulated on the traffic returns published yesterday. During the first fourteen days ending on Saturday last the receipts amounted to £1,947, showing that 233,640 passengers had been carried during that period, or on an average 16,688 per day; that is to say, nearly 40 per cent. more than was estimated by the pessimistic Mr. A. Willbond.

A note recently presented by Mr. Lucas to the *Comptes Rendus* on the Electro-magnetic Solution of Equations, raises a question of some interest. The applications of Mathematics to Physics have been both numerous and important, but few cases exist in which the process has been reversed; for, although experience of physical phenomena is sometimes useful in interpreting a solution, it has rarely served as a guide in

Digitized by Google

obtaining it. Mr. LUCAS has shown how the roots of an equation may be obtained by examining the magnetic field caused by passing currents of electricity through a number of parallel wires. The relative strength of the currents, and the position of the wires, is determined in a fairly simple manner from the numerical coefficients of the terms in the equation, and the points at which the magnetic force is zero indicate the solution of the problem. Although no one would attempt to solve an equation in this manner, the method is remarkable for its originality, and it is of interest to inquire whether mathematical processes would gain in usefulness by further attempts to solve problems in a similar manner. In applying analysis to explain a new physical phenomenon, it generally happens that the solution first obtained is unncessarily complex. This is often the case with alternate current problems, and the solution is usually simplified by merely ignoring some of the conditions of the problem, the consideration of which does not appear to have affected the answer practically, although it may have introduced complicated functions. Where the practical solution is known, it might, in some cases, be possible, by comparison with the complex theoretical solution, to arrive at rules of approximation which would be valuable both for practical applications and for mathematical theory.

THE dynamical experiments described in the paper on the measurement of electro-magnetic radiation are not only of great theoretical importance, but present a number of novel details in the apparatus employed. A brief abstract of the paper appeared in *The Electrician* (Vol. XXV., p. 210); but the text contains so much matter of interest that we reproduce it in full. While Mr. BOYS has enabled a new order of measurements to be made, dealing with thousand-millionth parts of a gramme, a suitable field is opened for such work in the dynamical treatment of those radiations which HERTZ has investigated statically. The practical application of Prof. J. J. THOMSON'S method of determining the conductivity of liquids by the opacity of thin sheets to oscillatory radiations, by the use of a duster soaked in water or dilute acid, is particularly novel, though such a homely screen seems to contrast in a singular manner with the minute delicacy of the fragile resonators and invisible quartz threads which were used. That the main results were negative does not detract from their interest; but it is obvious that such a research as this could not be carried on if the South Kensington and Paddington Underground Railway, which is threatened, should some day run almost beneath the laboratory.

As will be seen by the short article which is published in another column, the forthcoming Electrical Exhibition at Frankfort-on-Main is to be carried out with a characteristic thoroughness which deserves and probably will attain every success. "Object lessons" in electric traction, and the electric transmission of power from long distances will be provided on an extensive scale, and the electric motor is to be largely employed. We are also promised a series of tests of the various apparatus exhibited, with publication of the results obtained.

ON making inquiry from the London Electric Supply Corporation as to the progress which they are making with the repairs and reconstruction of their distribution plant, we learn that they have put down a set of transformers capable of supplying the whole of the demand which would be made, but they prefer to wait until the beginning of next month in order that they may provide a complete duplicate set. They have laid four mains of an aggregate length of about 40 miles. Two of these will easily carry the present load. The generating plant will also be in duplicate, the dynamos and engines from the Grosvenor Gallery having been arranged at Deptford for this purpose. There are four engines, two of 600 horse-power and two of 1,200 horse-power.

THE serious fire which recently destroyed an entire block of buildings in New York was attributed, by rumour, to some accident connected with the electric light. So many accidents have been put down to such a cause without any foundation whatever, that the statement did not appear to be worthy of attention. An evening paper, however, has stated that "it has now been definitely discovered" that the fire was "caused by two crossing electric wires." We have cabled to our New York correspondent to inquire as to the actual cause of the fire; and he replies, "Fire not electric, probably matches."

**Durham.**—A scheme is on foot to light Durham Cathedral by electricity, the motive power to be derived from the river Wear.

**Dusseldorf.**—The central station at this town is to be opened on August 1st. The price to be charged is equivalent to 11d. per Board of Trade unit.

**Institution of Electrical Engineers.—Change of Address.**—On and after the 25th inst. the address of the Institution will be as follows:—Victoria Mansions, 28, Victoria-street, Westminster.

**"Anales de la Electricidad."**—In consequence of the appointment of Señor D. Antonino Suarez Saavedra, the editor, as chief of the telegraph service of the Canary Islands, this periodical has ceased to appear.

**Electric Traction in Naples.**—The Naples Council of Public Works has approved of a project for the construction and working by electricity of the tramway from Naples (Musco) to Capodimonte and Miano.

**Birmingham.**—The Birmingham Electric Light and Power Company is rapidly progressing with the work of main-laying, and fair progress is being made at the generating station in Albert-street. Orders for over two thousand lights have already been received.

**Storage Battery Cars.**—The total mileage run during 1890 by the accumulator cars on the Barking-road line was approximately 80,000 car miles. According to schedule time the possible mileage was approximately 1 per cent. more than that actually run.

**The Telephone in Berlin.**—On December 17, 1890, the 15,000th telephonic apparatus was connected to the Berlin Exchange. The 10,000th telephone was installed April 18, 1889. The number of subscribers has, therefore, increased 50 per cent. in under two years.

**Electric Welding.**—M. Paul Hoho and a M. Lagrange, an officer in the Engineers, have devised a system of electric welding which is essentially different, so we are informed, to that of Elihu Thomson. The Hoho-Lagrange process will be worked in Belgium by the Julien Company.

Digitized by Google

**Telephonic Communication with Ships.**—The authorities of the Port of Bordeaux have decided to lay down a telephone cable to enable vessels in the roadstead at Pavillac, 26 miles distant, to communicate with the port.

**Cambridge.**—At a recent special meeting of the Town Council the Electric Lighting Committee recommended that application should be made to the Local Government Board to borrow the sum of £35,000 for the purposes of the Cambridge Electric Order, 1890. The report was carried with two dissentients.

**Personal.**—Mr. W. H. Stanger and Mr. Bertram Blount, of the Broadway Loboratory and Testing Works, Westminster, desire to correct a rumour which has become prevalent by stating that the Mr. William Fox who is at present associated with them at the above address is a member of the Institution of Civil Engineers, and not a practising analyst.

**Chelmsford.**—At the last meeting of the Town Council the Lighting Committee reported that they had appointed a small sub-committee to interview Messrs. Crompton and Co. as to the irregular working of the lamps, and they asked, if the interview was not satisfactory, for power to engage an expert to test the light. The recommendation was adopted.

**Electrical Transmission of Water-Power.**—The Gray Current Motor Company, of Elgin, Ills., has secured the large water-power at Oregon, Ills., and proposes to install a large electric water-power plant there. Large electric generators will distribute the power to manufacturing establishments in the town. A plant of a capacity to deliver some three thousand horse-power of electrical energy will be installed.

**Central Institution.**—A course of lectures will be given by Prof. Ayrton on accumulators, their manufacture, testing and practical applications; arc and glow lamps, construction, regulation, life, methods, and cost of electric lighting, electric traction; and the distribution of energy electrically, on Mondays and Wednesdays, from 3 till 4 o'clock, commencing Wednesday, January 14, 1891. Further particulars will be found in our advertisement columns.

**Institution of Civil Engineers.**—With a view to increase personal intercourse between the members of all classes, the Council have arranged for a series of receptions to be held after the ordinary meetings on Tuesdays, January 13th, February 3rd, March 3rd, April 7th, and May 5th. As it is believed that it will be convenient for the ordinary meetings to be closed at a somewhat earlier hour than usual, it has been decided to adjourn on these occasions at 9 p.m.

**Electric Traction Notices for 1891.**—In addition to Companies given in our list last week, the following have sent in notice of their intention to apply for powers to construct tramways and to make use of electrical or other motive power:—Southwark and Deptford Tramways Company in the Metropolis, and the Blackburn Corporation, the Bradford and Wyke Tramways Company, and a company to be formed to construct and work tramways at Matlock, apply for similar powers in the Provinces.

**Miniature Central Station Lighting.**—The little town of Vaison, in the Department of Vaucluse, which has only some 3,000 inhabitants, is now lighted by electricity on the Ganz system, the generating plant being over a mile and a-half from the town. The pressure employed is 1,800 volts. In a few weeks' time the little town of Monteux, in the same Department, will also be supplied with current on the alternate-current transformer system. In each case a single alternator of about 30 horse-power is used.

**Storage Battery Litigation in France.** — The Société Française d'Accumulateurs have just made some seizures of Tudor and of Bett accumulators. With regard to the Gadot accumulators which were impounded some time ago, the experts' report is expected to be published immediately. As to M. Julien, having recognised the Faure-Sellon-Volckmar patents and agreed to pay an indemnity to the Société Française, he has acquired the right to manufacture lead and lead peroxide accumulator plates on payment of a royalty of 20 centimes per kilogramme.

**Telegraph Statistics.**—With reference to our note under this heading, on p. 226 of our issue of December 26th, we are informed that the number of inland telegrams despatched in the United Kingdom during the year ending March 31, 1890, was 50,800,000, and including press, railway, Government, and foreign telegrams, 62,400,000. The figures in question related, however, in most cases, to the year 1888, and included only ordinary private messages, so that a comparison might be made of the degree to which the *bona fide* public utilised the telegraphic systems of their respective countries.

**Exeter.**—A meeting of the ratepayers was held on Tuesday evening to protest against the proposal recently made in the city Council to expend £30,000 on works for the supply of electricity. There was a large attendance. Captain Halford-Thompson stated that Exeter was deeply in debt. Their debt at the present time, including loans that have not yet been sanctioned, amounted to £400,000. In the face of this fact, and considering that sooner or later a vast sum would be required to improve their drainage, it would be very unwise to incur further expenditure. A resolution condemning the action of the Council was carried.

**Copper Statistics.**—The copper statistics do not show any special change during the month. The stock is a little less, but that is all, the visible supply in England and France and afloat thereto being 65,366 tons at the end of December, against 65,440 tons at the end of November. The present stock is about 33,500 tons less than what it was a year ago. The deliveries in England and France during December were 11,881 tons, or about 650 tons more than in the preceding month. For the year they aggregated 145,641 tons against 118,652 tons in the previous twelve months, and 63,906 tons in 1888.

**Vienna.**—A committee, consisting of Herren Bergk, Peters, and Klien, and Dr. Ulbricht, have been sent on behalf of the State Railways of Saxony to examine the Zipernowsky system of electrical distribution as laid down by the Internationale Elektricitäts Gesellschaft of Vienna.—On December 22nd a trial was made of the electric light installation at the Hofburg to the perfect satisfaction of the committee who have had the arrangements in hand. The work has been done by Messrs. Egger and Co., and the current is supplied by the Internationale Elektricitäts Gesellschaft. The Albrecht Palace, adjoining the Hofburg, is also shortly to be lighted throughout by electricity.

**The Telephone in France.**—According to the *Bulletin des Teléphones*, the number of subscribers to the nine chief telephone exchanges in France was at the end of November as follows:—

| | | | |
|---|---|---|---|
| Paris | 9,200 | Reims | 400 |
| Lyons | 800 | Roubaix | 350 |
| Marseilles | 600 | Tourcoing | 500 |
| Bordeaux | 500 | Nancy | 176 |
| Lille | 450 | | |

Cannes, Saint Étienne, Nantes, Troyes, Saint-Quentin, have about 150, and then come some thirty towns with from 50 to 100 subscribers each.

**Western Counties and South Wales Telephone Company.**—The following figures illustrate the remarkable appreciation by the public of the system of inter-urban telephone trunk wires which has been built up by the above Company in the West of England and the southern portion of Wales:—

| Period. | Miles of wire. | No. of communications. |
|---|---|---|
| 1888 | 1,387 | 284,886 |
| 1889 | 1,804 | 369,508 |
| 1890 | 2,215 | 496,520 |

**City and South London Railway.**—A correspondent points out in a financial contemporary that it is strange both the Board of Trade and the British public have overlooked the fact that the City and South London line is a railway, and that it was classed as such by the Board of Trade nearly a year ago. Yet the Company, whose railway is only 3¼ miles long, with stations about every half-mile, charges a uniform fare of twopence for any distance. It would be interesting to know, he remarks, whether the fact of charging twopence for any dis-

Digitized by Google

tance is not a violation of the Act stipulating that all railways shall run passenger trains at the parliamentary fare of one penny per mile.

**The Prague Exhibition.**—We are informed that January 31st is the last day on which applications for space can be entertained. The second section of the 27th group will consist of inventions, patents, &c., enjoying the protection of the Bohemian law. Foreigners may exhibit in this group. The charge for space is as follows: 1 square metre in the unroofed space, 2fl.; in a covered space, in the middle, 10fl. Half of the rent for space must be paid on presenting the demand for admission, and the second half on receiving certificate of admission. Awards will be granted by a special committee. English firms proposing to participate in this exhibition should apply to Arthur Gobiet, Karolinenthal, Prague.

**Hove.**—The Electric Lighting Committee of the Hove Commissioners have had under consideration the best means for carrying out their Provisional Order. Three modes were discussed:—(1) That the Commissioners themselves should carry out the Orders; (2) That the Commissioners should erect the buildings and provide the plant and mains, and then arrange with a Company to work the station; (3) That the Commissioners should transfer the undertaking to a responsible company. After full discussion the Committee have decided to recommend the adoption of the last of these modes. In order to obtain information for the Board, the Committee have selected Mr. R. E. Crompton as their consulting electrical engineer.

**Popp.**—The Compagnie d'Electricité Popp is determined to demonstrate the correctness of its title. A few weeks back the Conseil Municipal (see *The Electrician*, December 19, 1890, p. 195) spent several hours in discussing the fire at this Company's battery sub-station in the basement of the Grand Café, and a day or two ago a violent explosion occurred in another battery sub-station belonging to the same Company, at 20, Rue de la Verreris. According to *La Lumière Electrique* the batteries are installed in a dark, badly-ventilated cellar, and to prevent evaporation of the liquid it is covered with a thick layer of heavy petroleum oil, which itself gives off fumes. The result of these arrangements was an explosion when the cellar was opened one morning to permit of some workmen going into it to examine the cells.

**Colliery Lighting.**—The Golborne Colliery in Lancashire has recently been fitted with an interesting alternate-current transformer plant, designed to light the colliery both underground and on the surface, also to supply current for 150 16 candle-power lamps at the residence of the colliery owner at Golborne Park, about 1½ miles away. The dynamo is a 25-kilowatt 2,000-volt Mordey alternator. At the colliery itself there is a 300-light "Hedgehog" transformer. For the private house there is one 150-light "Hedgehog" transformer, and a 50-light transformer for the lamps lighting the drive, which is about a quarter of a mile long. The long-distance circuit is of 7/19 insulated cable, and is mostly run overhead upon poles and suspension wires. In order to comply with the requests of local authorities, wherever the cable crosses a road, which it does in three places, it is laid underground in suitably protected iron pipes.

**Snowstorms and Overhead Wires.**—Pittsburgh was visited about the middle of December by a terrific snowstorm, which rendered the streets almost impassable. According to the latest estimates the Western Union Telegraph Company and the District Telephone Company alone had their systems damaged to the extent of £10,000. Some 26in. of snow fell in 24 hours. The telegraph, telephone, electric light and electric street railway wires were covered with snow until the load often became too heavy and they snapped. In many instances where the wires did not break, the poles gave way under the heavy weight of snow and wires. The result throughout the city presented a complete scene of demoralisation as far as wires were concerned. Owing to the snow and sluish, as well as the condition of the wires, the electric roads had to suspend business altogther for a time. Out of 3,500 telephone wires 1,000 were broken down.

**Magnetic Observatories.**—At the present moment France leads the way as regards magnetic observatories where recording apparatus is in regular operation. These observatories are five in number, and are situated at Lyons, Perpignan, Nantes, Toulouse, and Clermont-Ferrand. At the observatory in the Parc St. Maur, Paris, magnetic observations are rendered impossible owing to the proximity and consequent perturbing effects of suburban railway lines. (See *Electrician*, Vol. XXIV., p. 566.) A sixth recording magnetic station is in course of completion at Besançon. Marseilles and Bordeaux also have obervatories, but there are no registering instruments at these places. M. Mascart's apparatus is used at all the six recording stations. After France comes England, with three magnetic observatories, and then Germany, Austria, and Portugal with two each. Russia, Spain, Belgium, and Holland have each one station, while Italy, but for the liberality of the Vatican. would be without any.

**Fire at West Drayton.**—We regret to have to record that a serious fire took place on Tuesday morning in the works of the Electrical Engineering Corporation. When the first workmen arrived, shortly before 5 a.m., the fire was not at first apparent, but on opening a door, a room in which it had been smouldering burst into flames. Hydrants had been provided, but before enough men had arrived the fire had got a good hold on the fitting and erecting shops, and the valuable tools and stock in them were destroyed. Although the damage, which amounts to about £15,000, is largely covered by insurance, the loss of a number of new tools, among them a large planing machine which had not yet been used, is very unfortunate. We learn that the smaller dynamos and other light work can be carried on in the buildings which were saved by the use of the hydrants, when it was too late to stop the conflagration. The Electrical Engineering Corporation were among those firms who assisted Messrs. Willans and Robinson after the fire at Thames Ditton, and we hope that they will, if need be, receive similar help.

**Arc Lights and Insects.**—Chicagoans who spent the summers of 1889 and 1890 in the city might, says the *Western Electrician*, with reason feel that there was a time when the electric arc lamp could be called a nuisance. Night after night the brilliant white light from the lamps on the streets of Chicago was the means of attracting vast swarms of bugs which filled the lamp globes and covered the pavements. Where these little insects came from it was difficult to say, but one thing was certain, they were a nuisance, and the electric light brought them together in great numbers. With this in mind, Chicagoans will be interested to read of the novel manner in which the electric arc lamp is employed in Bavaria to attract forest bugs to destruction. A beautiful park near Munich, Bavaria, had suffered from their depredations. At last a large arc lamp and reflector were set up in the forest. The lamp was located at or near the mouth of an opening leading from a powerful exhaust fan. This fan discharged into a grinding mill. This tells the story. The Bavarian bugs proved as partial to the arc light—and the grinding mill—as the Chicago sand flies.

**New Aluminium Alloys.**—Quite recently experiments, says the *Engineer*, have been made at the department of aërial navigation for military purposes at Chalais, with light aluminium alloys, and have been attended with an encouraging measure of success. The aluminium used was obtained from the Société de l'Aluminium, and was very nearly pure. Copper in the form of ordinary conducting wire was used to alloy with it, the whole being rolled into sheets 1mm. in thickness. Strips having a width of 5mm. were cut from these and tested, with the following results:—

| Composition. | Specific gravity. Calculated. | Specific gravity. Determined. | Tensile strength. kilos. per sq. mm. | Tons per square inch. |
|---|---|---|---|---|
| Aluminium | — | 2·67 | 18·7 | 12·0 |
| " 98 p. c., Copper 2 p. c. | 2·78 | 2·71 | 30·7 | 19·65 |
| " 96 p. c., " 4 p. c. | 2·90 | 2·77 | 31·1 | 19·9 |
| " 94 p. c., " 6 p. c. | 3·02 | 2·82 | 38·6 | 24·7 |
| " 92 p. c., " 8 p. c. | 3·14 | 2·86 | 35·5 | 22·7 |

These figures are sufficiently remarkable; the addition of only 2 per cent. of copper is seen to increase the tensile strength from 18·7 to 30·7 kilos. per square mm., while 6 per cent. more than doubles it.

**National Telephone Company.**—Special call-boxes have been opened at Oxford-court, Cannon-street, for telephonic con-

Digitized by Google

versation with Manchester, Liverpool, and Birmingham, and arrangements will shortly be made to give similar communication with Leeds, Bradford, and other centres of business. The charge for three minutes' conversation is as follows:—To Manchester, 3s.; Liverpool, 3s.; Birmingham, 1s. 6d. Subscribers wishing to talk direct from their own offices will be supplied with a separate exchange line, and suitable apparatus, at an extra cost of £15 per annum. They will be required to make a deposit with the Company of £5, and will receive a monthly statement of accounts for calls made during the month. In the metropolitan exchange system, second and additional exchange connections for business addresses will be reduced to £15 per annum for each connection after the first when within a radius of two miles of the Company's nearest exchange. The Company is now engaged in remodelling its system, and in the course of doing so the new wires, whilst being run, are sometimes unavoidably thrown into contact with those in use, and so cause disturbance in the service. Under these circumstances, the directors ask for friendly consideration, and a report to the secretary of any fault that may arise.

**Destruction of a Melbourne Electric Light Station by Fire.**—A disastrous fire occurred on the premises of the New Australasian Electric Lighting Company on November 16th. The building had been in the occupation of the Company for some nine years, and was partly two-storied. The upper story was utilised as officers' quarters and store room. All the machinery was on the ground floor. The steam plant comprised four large engines and boilers, two of the engines being by Ganz and Co., and the others by Marshall. The electrical plant comprised two 1,200-light Ganz alternators, and several Brush machines. The flames quickly obtained such a firm hold that the building was almost completely gutted before they could be subdued. Apart from the serious destruction of property, the fire caused considerable public inconvenience, as from these works the electric light was supplied to the Grand Hotel, Victoria Coffee Palace, Theatre Royal, and a number of smaller establishments. According to an engine-driver employed by the Company, he noticed, at 11:10, a flame on the switch-board, near the Theatre Royal switch. The flame ran along the board, and he and other *employés* tried to extinguish it with a bucket of water, but could not do so. The hose on the premises was then put on, but it burst. In a very little time the flames had possession of the building.

**The Photographic Action of Electro-magnetic Waves.**—In the *Wiener Berichte* of October 9, 1890, Franz von Dobrzynski says: I have for several months been engaged in investigating the photographic action of electro-magnetic waves. The electro-magnetic waves were obtained by the method of Hertz. They acted on dry bromide of silver and gelatine "Nys" plates procured from Geissler in Bonn. The plane of the plates either included the axis of the vibrator, or was at right angles to it. The exposure was three hours. No sensitisation of the plates was made. The development and fixation took place in the ordinary manner by ferric oxalate and hyposulphite. The action was visible after development and fixation by the appearance of alternating bright and dark bands across the direction of vibration of the waves, or by the appearance of dark bands in the direction of the vibration. Both kinds of bands could occasionally be observed together. In many experiments the plates were covered with tinfoil. Portions of the coating of the tinfoil were cut away. The tinfoil did not prevent the formation of bands. This points to the fact that the chemical action which here comes into play is not a primary one. The cross bands suggested stationary vibrations. They might be due to reflexion from the sides of the wooden box, by which the plates were protected from the influence of extraneous rays; but they might also owe their origin to reflexion from the side of the room. The only experiment which could be made with a reflecting metal ball was not in disagreement with this view; the cross bands were now more distinct and regular. If this view is correct, it may be concluded that waves of from 0·6 to 20 centim. are effective.

**The Magneto-Optical Generation of Electricity.** — Prof. Brackett and Mr. S. T. Dodd, of Princeton College, N.J., write to the *Electrical Engineer* of New York as follows:—"We have endeavoured to produce an electric current in the manner described by Prof. Sheldon in the *American Journal of Science*, September, 1890 (*Electrician*, Vol. XXV., p. 559), and we have also endeavoured to produce it by other similar means which his experiment suggested, but with entirely negative results. We first followed as nearly as possible the arrangement of Prof. Sheldon; the only essential change which we made was in the substitution of a glass tube for the brass one on which the coil was wound. The experiment was carried out with the result that faint musical sounds were heard in the telephone, which could be referred either to the action of the arc lamp or to the moving machinery. On interrupting the ray of light no change whatever was produced. We next discarded the oscillating apparatus, and substituted one by means of which we could rotate the Nicol prism about 200 times per second. . . . We failed, however, to obtain any indication of a direct current by the use of a delicate galvanometer, or of an interrupted current by means of a telephone, when the ray of light was rapidly and periodically interrupted. In the third place, if an electro-motive force can be induced by mechanically superimposing a third rotation upon the two existing rotations which are regarded as the equivalent of a plane polarised ray, then a still greater electro-motive force should be induced by suppressing one of the original rotations —that is to say, by using circularly polarised light. Accordingly this plan was employed, and with negative results."

**Lightning on a Lighting Circuit.**—The following account of some lightning strokes on electric lighting apparatus in a Michigan town during storms on August 8th and September 6th, 1890, may prove of interest to central station men. It is an extract from a lengthy report to the *Western Electrician.* At the station, on August 8th, the lightning arresters were marked by discharges, the discharge combs being burned considerably, one tooth being fused enough to make contact with the plate opposite itself, causing ground connection. The main switch was open, so that nothing was in circuit at the station except the lightning arresters. The primary fuses of five out of six converters were blown on both sides. The secondary of the sixth converter was open, so its impedance was at its maximum. One of the others had its secondary open also. All the other secondaries were closed. One converter was tested after the storm and found to be all right, and the others appeared none the worse for their experience. On the secondary circuits a 10-ampere branch fuse was knocked out, and 52 16-candle-power lamps had filaments broken. All the lamps that were up seemed to have been strained, and are breaking rapidly. A peculiar thing about the 10-ampere fuse being blown is that there was no circuit through it, the lights which it protected having been all turned off the night before, and at least three-fourths of the number of lamps which were damaged were turned off by key or switch; indeed, some of them were absolutely disconnected from the converters. The filaments in some lamps were blown to pieces; in others they had broken away from both platinums and were sticking to the inside of the glass. The insulation of the circuit is very good, unusual pains having been taken with it, both on primaries and secondaries, and there is no sign of a break to earth from the circuit anywhere. Whatever effects followed the lightning are not due to the circuits acting as a lightning rod. On Saturday, September 6th, during a violent storm, the saw teeth plates on the switch-board were melted at the edges and fused together so that the current generated by the dynamos ran straight to the ground, and the engineer was compelled to shut down. That was the only damage done on the second occasion.

**Magnetism and Recalescence.**—In a Paper on this subject recently read before the Royal Society, Dr. John Hopkinson describes some experiments carried out by him to obtain absolute proof that change of magnetic property occurs exactly when heat is liberated and absorbed. A copper wire for measuring temperature was well insulated with asbestos and laid in a deep narrow groove running round the iron ring. The secondary exploring coil was then wound on, next a serving of asbestos paper and mica, and then the primary coil, and, lastly, a good serving of asbestos paper was laid over all. The whole was placed in an iron pot, and this

Digitized by Google

again in a Fletcher gas furnace. By this arrangement it was possible to compare directly at the same instant the magnetic and thermal condition of the ring. In a sample of iron containing about ·3 per cent. carbon only a cooling curve was taken. In iron of this composition Osmond has noticed that there are two successive temperatures of recalescence. It was observed that there was considerable liberation of heat at 715° C., continuing for ten minutes to 660° C. At 660° C. the rate of liberation became so rapid that the fall of temperature was for several minutes almost arrested. Liberation of heat then ceased and normal cooling continued. Comparing the kicks of the galvanometer, it was observed that the ring began to be magnetisable at 715° C., and its magnetic property increased till the temperature of 660° C. was reached; after this point the magnetisability increased much more rapidly, and was practically fully developed immediately after the normal rate of cooling was recommenced. In this case the development of magnetic property followed precisely the whole of the liberation of heat, observed both at the temperature of about 700° C. and at 660° C. A magnetising force of 6·56 was employed. With a ring containing 0·9 per cent. of carbon the heating curve showed that there was a slight absorption of heat at 710° C. with doubtful effect on the magnetism. At 770° C. powerful absorption of heat began and continued to 808° C; it was between these times that the magnetisability was decreasing, and at the latter temperature it finally disappeared. The heating was continued to about 840° C. In cooling, heat was liberated at one point only, with a distinct rise of temperature. Recalescence began at 750° C., and it was precisely at this temperature that the ring began to be magnetisable. Recalescence continued for 21 minutes, and at the end of this time, and not before, the magnetisability attained a maximum. The ring was then heated to 966° C., and the curve showed plainly the effect of higher heating in *lowering* the temperature of recalescence, which had fallen from 750° C. to about 680° C. These experiments show that the liberation and absorption of heat known as recalescence, and the change in magnetic condition, occur simultaneously. Also that in the case of steel with 0·3 per cent. of carbon both temperatures of liberation of heat are associated with change of magnetic condition.

**A Windmill-Dynamo Plant.**—The huge windmill-dynamo plant erected by Mr. Brush in his back garden at Cleveland has attracted considerable attention in America, and as plants of this description are sufficiently rare, the following particulars may be of interest:—The windmill-tower, says the *Scientific American*, is rectangular in form and about 60ft. high. It is mounted on a wrought-iron gudgeon 14in. in diameter, and extending 8ft. into the solid masonry below the ground level. The gudgeon projects 12ft. above the ground, the weight of the tower, which is nearly thirty-six tons, being borne by a step resting on the top of the gudgeon. In the upper part of the tower is the main windmill shaft. This shaft is 20ft. long and 6½in. in diameter, and carries the main pulley, which has a diameter of 8ft. and a face of 32in. The windmill wheel is 56ft. in diameter, the sail surface being about 1,800 square feet. The length of the tail which turns the wheel toward the wind is 60ft., and its width is 20ft. The mill is made automatic by an auxiliary vane extending from one side, and serving to turn the wheel edgewise to the wind during a heavy gale. The countershafting arranged below the main shafting is 3½in. in diameter, and carries a pulley 16in. in diameter, with a face of 32in., which receives the main belt from the 8ft. pulley on the main shaft. The countershafting is provided with two driving pulleys, each 6ft. in diameter, with a face of 6½in., and the dynamo is furnished on opposite ends of the armature shaft with pulleys which receive belts from the drive wheels on the countershaft. The dynamo is mounted on a vertically sliding support, and is partially counterbalanced by a weighted lever. The countershafting is suspended from the main shaft by the main belt, and the dynamo is partly suspended from the countershafting by the driving belts. In this way the proper tension of the belts is secured. The ends of the countershafting are journaled in sliding boxes connected by equalising levers, which cause both ends of the shaft to move alike. The dynamo makes fifty revolutions to one of the wheel. The maximum speed of the dynamo is 500 revolutions per minute, the peripheral velocity of the windmill being therefore then 1,800ft. per minute. The automatic switching devices are arranged so that the dynamo goes into action at 330 revolutions, and an automatic regulator is provided which does not permit the electromotive force to run above 90 volts at any speed. The working circuit is arranged to automatically close at 75 volts and open at 70 volts. The brushes on the dynamo are rocked automatically as the load changes. In the basement of Mr. Brush's house there are 408 secondary cells arranged in twelve batteries of 34 cells each, which are charged and discharged in parallel. Each cell has a capacity of 100 ampere hours. The house is fitted with 350 incandescent lights, varying from 10 to 50 candle-power each, about 100 incandescent lights being in every day use. In addition to these lights there are two arc lights and three electric motors. This plant has been in constant operation more than two years, and has proved in every respect a complete success.

**The Inductance in Henrys of Common Instruments, &c.**—The following figures are taken from Mr. Kennelly's Paper. which is concluded in this issue, and are here placed in order of magnitude to convey a clear idea of the practical meaning of a henry. The last items in the list appear to be very high, no such inductance is to be found in armatures of ordinary dynamos. Very large arc light machines are probably referred to:—

| | | |
|---|---|---|
| Hertz resonators about | $\frac{1}{10}$ | microhenry. |
| Cardew voltmeter | 1 | ,, |
| Doubly-wound resistance coil | 1 | ,, |
| One section of a dynamo armature | 1 | millihenry. |
| Secondary of transformer (ratio 20) | 1 | ,, |
| No. 11 copper wire, per mile, 13ft. high | 2·84 | ,, |
| ,, ,, ,, 23ft. ,, | 3·02 | ,, |
| No. 19 ,, ,, 13ft. ,, | 3·2 | ,, |
| ,, ,, ,, 23ft. ,, | 3·4 | ,, |
| Telephone induction coil primary ·28 ohm | 3·5 | ,, |
| Medical induction coil, small, primary | 5· | ,, |
| Ordinary electric bell | 12 | ,, |
| Dynamo armature, from | 20 | ,, |
| Mutual inductance, transformer, from | 20 | ,, |
| ,, ,, small medical coil | 20 | ,, |
| Ordinary telegraph sounder | 25 to 50 | ,, |
| Telephone induction coil, mutual | 60 | ,, |
| Telephone Bell receiver, diaphragm removed | 65 | ,, |
| ,, ,, diaphragm on | 100 | ,, |
| Telephone induction coil, secondary | 100 | ,, |
| 10 ohm relay armature set back | 200 | ,, |
| ,, ,, ,, against poles | 500 | ,, |
| Transformer, primary, from | 400 | ,, |
| Telephone induction coil, secondary, 164 ohms | 734 | ,, |
| Field magnets of small dynamo, from | 1 | henry. |
| Telephone call bell (80 ohms) | 1·4 | ,, |
| Astatic mirror galvanometer (500 ohms) | 2 | ,, |
| Telephone magneto, core opposite to poles | 2·7 | ,, |
| ,, ,, ,, ,, right angles to poles | 7·3 | ,, |
| Mirror speaking galvanometer (cable), 2,250 ohms | 3·6 | ,, |
| Western Union, 140 ohm relay, armature back | 3 | ,, |
| ,, ,, ,, ,, ,, adjusted | 5 | ,, |
| Western Union, 140 ohm relay, armature against poles | 9 | ,, |
| Dynamo armature, up to | 50 | ,, |
| ,, field magnets, up to | 900 | ,, |

To these we add some of the values given in the Papers by Profs. Ayrton and Perry, read in March, 1889, before the Institution of Electrical Engineers:—

| | | |
|---|---|---|
| Single coils of Morse receiver, 32 ohms | 93 | millihenrys. |
| ,, ,, ,, 50 ohms | 444 | ,, |
| Two coils, with armature | 265 | ,, |
| Voltmeter coil, no iron, 333·5 ohms | 1·46 | henry. |
| Single coil of reflecting galvanometer, 2,700 ohms | 2·56 | ,, |
| Single coil of reflecting galvanometer, 100,000 ohms | 70 | ,, |
| Induction coil, 2in. spark, secondary | 51·2 | ,, |
| ,, ,, ,, mutual inductance | 460 | millihenrys. |
| Ferranti dynamo, 200 volts. 40 amps. armature. | 1·3 | ,, |
| ,, ,, magnets | 610 | ,, |
| Shunt dynamo, 100 volts 35 amps. armature. | 5 | ,, |
| ,, ,, magnets in series | 13·6 | henrys. |

## MAGNETISM IN IRON AND OTHER METALS.*—XXXIX.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 229.*)

§ 140. **Transient Currents produced by Magnetising Twisted Rods, or by Twisting Magnetised Rods.**—The sudden development of circular magnetism when a longitudinal magnetised rod is suddenly twisted, or when a longitudinal magnetising force is suddenly applied to a rod that is held in a state of torsion, is well shown by connecting the ends of the rods to a galvanometer, when it will be found that a transient current is induced along the rod. A still more effective experiment may be arranged by substituting a tube for the solid rod, and by placing within it an insulated wire in circuit with the galvanometer.† In experiments of this class the existence of hysteresis is shown in an interesting way by making back and forth twisting take place in a series of steps, when, by summing the transient currents, it is at once seen that the circular magnetisation exhibits hysteresis with respect to the angle of twist—a result which is of course to be anticipated from the known effects of pull and push. Thus in Fig. 117 an iron wire rather strongly magnetised in the direction of its length was twisted alternately to opposite sides, but the twisting was done in a series of steps, and the transient current for each step was noted.

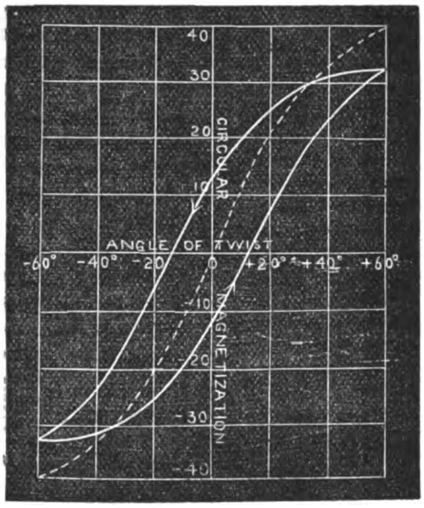

FIG. 117.—Circular Magnetisation produced by Twisting Magnetised Iron.

Summing up the transient currents we obtain the circular magnetisation in arbitrary units. The full lines of the figure show how the circular magnetisation was cyclically reversed by reversing the twist, but the change of circular magnetism lagged behind the change of twist.‡ The dotted line in the same figure exhibits the amount of circular magnetism found by first applying a given torsion and then reversing the longitudinal magnetising force. This procedure, of course, eliminates the hysteresis which appears in the other.

Fig. 118 gives the results of a similar experiment made with a piece of pianoforte steel wire in its usual condition of temper. The dotted line has the same meaning as in Fig. 117.

In these cases the process of back and forth twisting had been repeated often enough to bring about a cyclic *régime* before the observations were taken. It is interesting to notice the manner in which the cyclic state is reached. This is shown in Fig. 119, which relates to the same wire as Fig. 118. Starting from the condition that had been reached by reversing the longitudinal magnetisation, when the angle of twist was +90deg., the changes shown in the diagram were brought about by twisting back to −90deg., again to +90deg., back to −90deg., and again to +90deg.

In all these cases the direction of the circular magnetisation was such as would correspond to *increase* of magnetism by pull. And a careful inquiry has shown that the effect of torsion is not reversed, though the longitudinal magnetising force be made very great. What happens in that event is that the tansient currents due to torsion become much weakened; but their sign does not change. Here, again, the explanation is that the intensity of magnetism on which the pull and push of

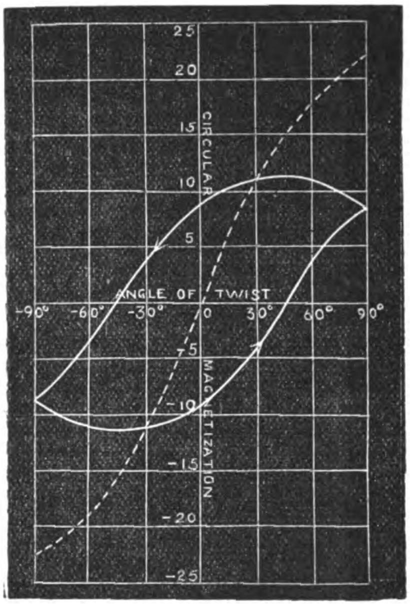

FIG. 118.—Circular Magnetisation produced by Twisting Magnetised Steel

the torsion act, is the component at 45deg. to the axis, and this remains below the Villari critical value, even when the whole magnetism approaches saturation* (*see* § 138, above).

When this longitudinal magnetism is residual instead of in duced, torsion still produces transient currents of the same general character, but the effects are complicated by a progressive shaking out of the magnetism.†

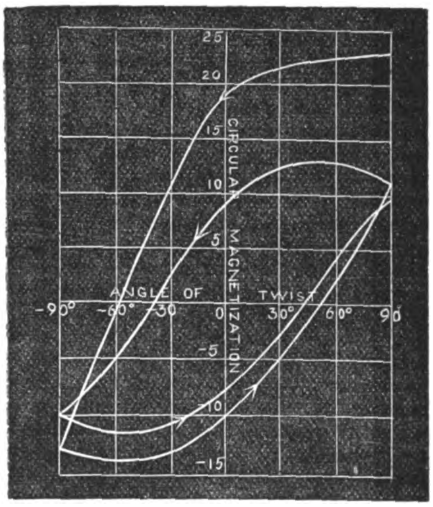

FIG. 119.—Effects of Twist.

Using a telephone in place of a ballistic galvanometer, Hughes has observed the production of transient currents in a twisted wire, when the current in a surrounding solenoid is rapidly interrupted or reversed. He has also illustrated the production of longitudinal out of circular magnetism in a twisted

wire, by passing an interrupted current through the wire, and putting a telephone in circuit with a coil wound round the wire.*

In nickel, the effects of simple pull and push are, as we have seen, opposite in sign to the effects in iron, provided the magnetisation of the iron is not so great as to cause the Villari reversal. Hence we may expect the transient currents produced by twisting a longitudinally magnetised nickel rod or tube to take the opposite direction to that which they take in iron. This fact has been verified by the independent experiments of Zehnder † and Nagaoka‡, who found that when a nickel wire is twisted as a right-handed screw the transient current flows from the south to the north pole.

## THE INTERNATIONAL TELEGRAPH BUREAU AT BERNE.

The Bureau International des Administrations Télégraphiques, to give it its official title, was created by the Vienna Conference of 1867, and its objects are defined in the St. Petersburg revision of the International Telegraph Convention under the following heads:—(1.) To collect, arrange, and publish all kinds of information relating to International Telegraphy. (2.) To circulate requests for the modification of tariffs or for the alteration of the service regulation. (3.) To notify all changes of tariffs and rules to every administration.

The first object is partly attained by the publication of an official journal, the *Journal Télégraphique*, issued every month, the editor of which is the Director of the International Bureau for the time being. The present Director, Dr. Rothen, has for years past contributed scientific articles to this journal.

Once every year the Bureau issues a form to every Administration to be filled up, giving the length of line, number of stations, instruments, staff, and forwarded, received, and transmitted telegrams. The receipts from telegraphic work, and the expenses in connection therewith, are also asked for, but a large number of the States fail to give this information in consequence of their postal and telegraph accounts not being separately kept. When this information is received at Berne, it is published in a tabulated form, generally 18 months to two years after date. These statistics are not quite so serviceable as they might be, since some States do not regularly supply the information asked for. One of the Administrations has not supplied anything since 1870.

Another most important work of the Bureau is the preparation of official telegraph maps of three different kinds:—(1) A small map of the world; (2) A large map of the world on Mercator's projection; (3) A large map of Europe and the countries adjacent to the Mediterranean. These maps are executed with great care and accuracy, and form an invaluable adjunct to a telegraph office.

A list or "nomenclature," containing the name of every telegraph station in the world, and the country in which it is situated, is also published and kept revised by bi-monthly circulars. This list is an absolute necessity to a telegraph station. Another publication is a list of all the submarine cables of the world, giving their length, date of immersion, and ownership. Fresh editions of the maps, nomenclature, and list of submarine cables are published every two or three years.

The second part of the duties of the International Office is performed chiefly by means of ordinary correspondence, and also by the issue of circulars to all administrations. It very seldom happens however that any of the regulations are altered between the Conferences.

The third part of the duties of the International Office is performed by means of notifications, telegraphic and postal. The telegraphic notifications relate principally to the interruption or restoration of submarine cables and main line routes, also to sudden changes of tariff by non-adhering administrations. The ordinary notification is issued on the first of each month, and contains notices of alteration of tariff, confirmation of previous telegraph rates, opening of new routes, and a host of information which is of great service to all administrations. Occasionally the Berne Office has to publish one or more supplementary notifications in the course of the month, owing to the large amount of information coming to hand.

One of the most important duties of the International Bureau is the preparation for the quinquennial Conferences. It has to prepare and publish all propositions for the alteration or regulation of tariff. The Director and Secretary attend the Conferences, take the minutes of all the various sittings, and after the Conferences are over publish all the acts of the Conferences, together with the tariff lists, and a mass of information relating to various subjects. It may be safely said that during the sitting of the Conference the hardest worked men are the Director and Secretary of the International Bureau.

One other duty has been placed upon the Bureau by the last Conference at Paris—viz., the compilation and publication of an authorised vocabulary, the use of which will be compulsory in the European *régime* for code telegrams, a work that will occupy the office for at least two or three years, and, when finished and in operation, will be of immense use, both to the telegraph service and to the public.

The International Bureau is placed under the control of the Swiss Government, and consists of a director, secretary, and three or four clerks. The Director has always previously occupied the post of Director-General of Swiss Telegraphs. M. Curchod was the first Director, and he was succeeded by M. Lendi, and on this gentleman's decease M. Curchod again took up the duties. M. Curchod died in October, 1889, and was succeeded by M. Frey, who died in June, 1890. Dr. Rothen has recently been appointed Director. M. St. Martial, the first Secretary, died in May, 1885, and was succeeded by M. Eschbaecher, who has made himself universally popular with all who have been brought in contact with him. At the London Conference a pension scheme was authorised for the officials of the International Bureau. The expenses of the International Office are paid by all the administrations adhering to the Convention, in certain proportions agreed upon at each Conference, and its accounts are published, duly audited by the Swiss Government every year.

The International Telegraph Bureau at Berne, it will thus be seen, is an institution which performs many most useful functions, and as time goes on its utility is in no way likely to be diminished.

## AN IMPROVED PROCESS FOR THE PRODUCTION OF COPPER.

Copper is a material of such supreme importance to the electrician that any advance in its method of manufacture must be of direct interest to him. Mr. Percy C. Gilchrist has recently communicated to the London section of the Society of Chemical Industry the results he has obtained by applying what is known as the "basic process" to copper refining.

In the production of steel by the original Bessemer process, only pig iron free from all but a very small amount of phosphorus could be used, owing to the facts that phosphorus has a most deleterious influence on the finished metal, and that it was not eliminated in the natural course of events. By the substitution of a "basic lining" (*i.e.*, one composed of material such as magnesia) for the "acid lining," composed of siliceous matter, such as sand or ganister, it was found possible to remove the phosphorus owing to its tendency to become oxidised to phosphoric acid and combine with the basic material. It therefore seemed probable that the same device would be applicable in the case of copper for the removal of

Digitized by Google

arsenic — the electrician's *bête noir*. The high price of copper of good conductivity mainly depends on the cost of the elimination of those impurities which are, perhaps, more objectionable for electrical purposes than for any others.

Mr. Gilchrist's experiments have taken practical shape, and at least one big copper company is using furnaces with basic linings. Speaking generally, the value of the process lies rather in the elimination of arsenic more readily and at a cheaper rate (less copper passing into the slag and having to be reworked) than in any extraordinary perfection in the refined product. Its adoption should, therefore, lead to a reduction in the price of copper of good, but not abnormally good, conductivity, rather than to the attainment of any remarkably low resistance. Since it has become common practice to specify 98 per cent. conductivity, and such a conductivity being easily attained, manufacturers would do well to try and reduce the cost rather than to attempt to produce an article of greater purity but at a higher price.

## ELECTRO-MAGNETIC MECHANISMS.

### PRESIDENTIAL ADDRESS TO THE JUNIOR ENGINEERING SOCIETY.

BY PROF. SILVANUS P. THOMPSON, D.SC., B.A.

*(Continued from page 271.)*

*Some Paradoxical Cases.*

Passing on from these devices, I now invite your attention to another rather curious experimental result.

One consequence of the rule that the magnetic stress across a gap in the circuit is proportional to the square of the intensity of the magnetic flux, is the paradox that the pull exerted on an armature by an electro-magnet having a straight cylindrical core, is diminished by enlarging the surface of contact, and increased by somewhat diminishing that surface. This seems to be in direct opposition to all ordinary notions of mechanical structures; but it is, nevertheless, quite rational. If we diminish the end surface of the core, say 10 per cent., we shall produce thereby really very little difference in the total flux of magnetic lines, since the main reluctance to magnetisation lies in the long return path through the air. But if the flux of magnetic lines is now crowded into a lesser area, the intensity of the flux—that is to say, the number of magnetic lines per square inch—will be greater, and the square of this quantity will be, *à fortiori*, greater still. Now the pull exerted at the surface is equal to the product of this greater square number into the diminished area of surface; and as the increase in the square of the induction is greater than the decrease in surface, the nett result is that the pull is increased. Conversely, enlarging the contact surface diminishes the pull. This goes entirely against all preconceived notions of mechanical engineering; for the first instinctive impulse of an engineer, when he wants to strengthen the joint between two things, is to enlarge the surface of contact at the joint. Some diagrams that hang upon the wall (reproduced in my recent "Cantor Lectures") exhibit the results of a series of experiments by Dr. Julius Dub upon the deleterious effect of adding polar expansions to the end of an electro-magnet.

Another strange and interesting fact is that the pull exerted upon a piece of iron by a straight electro-magnet can be considerably increased by attaching a large mass of iron to the other end of the core of the electro-magnet. This is at once explained by reference to the principle of the magnetic circuit; for the mass of iron at the idle end of the core aids in the return of the magnetic lines through the air.

*Equalisers.*

I may now proceed to the consideration of sundry pieces of mechanism, in which an electro-magnet in one or other of its varied forms is combined with some other contrivance of a mechanical nature. In the first place I will deal with the subject of *equalisers*, or devices for equalising the otherwise unequal forces exerted by an electro-magnet on its armature when the latter is at different distances. You will have realised how, for example, with the ordinary two-pole or horse-shoe form of electro-magnet, the pull will become greater as the armature approaches, because as the gaps between it and the iron core are diminished, the resulting betterment of the magnetic circuit both increases the actual flux of magnetic lines and diminishes the amount of magnetic leakage. The variations of this force cannot be accurately expressed by a law of inverse distances or of inverse squares or cubes, and I shall not attempt the hopeless task of trying to fit a law to them. If an armature placed below the poles of such an electro-magnet at a little distance away is not constrained by any other opposing forces than that of its own weight, it is evident that there must be one particular strength of electric current which will just suffice to magnetise the electro-magnet sufficiently to overcome the downward pull of gravity, and raise the armature; but when once the armature has begun to rise, its mere approach betters the magnetic circuit and increases the upward attraction, so that it will be pulled right up to the pole. A strong current will perform no more in this case than one that is just strong enough to start the action. If, however, such an armature be controlled, not by the mere force of gravity, but by a spring so designed that, as the armature moves nearer to the poles, the opposing force of the spring shall be greatly increased, then a weak current will only produce a small motion, and a stronger current a larger motion, and there will be a determinate position of the armature corresponding to all different strengths of currents within the working limits of the apparatus. It is clear, then, that a properly designed spring, or combination of springs, may be used to equalise the movements of the armature in more or less strict proportion to the electric current. A device of this kind, with a series of set-screws behind a spring at different distances to stiffen it as it was moved, was indeed invented by Callaud, a French engineer. Another mode of equalising is by a

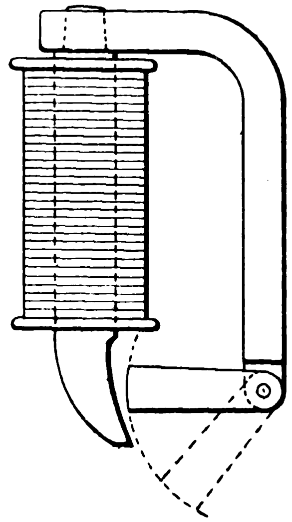

FIG. 10.

pair of rocking-levers which cause the armature as it approaches the poles to work with a lessened mechanical advantage. Equalisers on this plan were first suggested by the conjuror, Robert Houdin, and one used in the mechanism of several arc lamps. Another inventor, Burnett, has proposed to act on one armature by means of several electro-magnets which should successively be brought into play. A purely electrical method of equalising consists in arranging a series of contacts in the path of the armature, so that as it approaches the poles it should successively shunt out of action portions of the exciting current. Another device due to Froment consisted in applying a reversed Stanhope lever to the armature. Other varieties of linkage might doubtless be arranged to attain the same end. But the most interesting kinds of equalisers are those which depend on magnetic principles. It is possible, for example, by the device of shaping away the polar surfaces or by adding pole-pieces of appropriate shape to cause the approach of the armature to exert a very slight betterment of the magnetic circuit. One of such devices is depicted in Fig. 10, and consists in pivoting the armature to one pole of an electro-magnet, the other pole of which is provided with a curved pole-piece. By varying the contour of the latter any desired change may be made in the distribution of the pull at various points of the travel. In this particular instance, as the armature moves nearer, as a whole, it increases its distance from the curved pole-piece. An electro-magnet resembling this is used in Messrs. Paterson and Cooper's Phœnix arc lamp.

*Devices Based on Oblique Approach.*

It is not very easy to draw a hard-defining line between this device and another, due to Froment, who pivoted his armature upon two parallel levers, like the connecting bars of a parallel ruler,

Digitized by Google

and thus constrains the armature to move (parallel to itself) along a curve, which, though it approaches very near to the poles, falls short of actual contact. Devices with oblique approach have often been used in small electro-magnetic motors. One of these, due to Wheatstone, is depicted in Fig. 11, in which it will be seen that an electro-magnet, pivoted so as to revolve on its own middle, is surrounded by an iron ring through which the magnetic lines can stream back from the north to the south pole. The inner face of this ring is cut away in an oblique manner. Applying our principle that there is a tendency of the configuration so to alter as to complete the magnetic circuit as much as possible, it is evident that the electro-magnet will turn until the gaps are reduced to a minimum If at this point the current is cut off, the electro-magnet. will be carried on over the dead points, and may be again switched (automatically) into circuit, to be again attracted forward, and

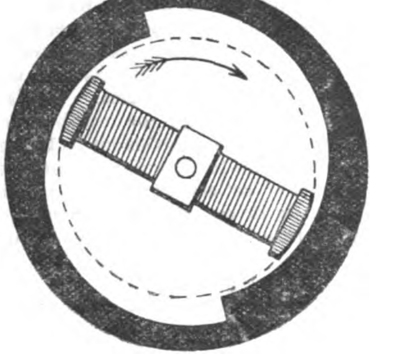

Fig. 11.

so forth. The analogy between this piece of magnetic mechanism, and the familiar mechanical device known as the cam, will be at once apparent. This is by no means the only instance of an electro-magnetic cam to be found amongst the practical applications of the science. All the electro-magnetic devices for distributing the pull of an electro-magnet, whether they consist in shaping the pole-pieces or the armatures, or whether they consist in constraining or pivoting the armature or the electro-magnet in the modes previously suggested, may be considered magnetically as either cams, wedges, or inclined planes.

*Pivoted Mechanisms.*

Beside the devices which I have already mentioned there are several for producing movement about or upon an axis. Some of these are designed for telegraphic purposes. For example, in Fig. 12 is depicted the method adopted by Siemens 40 years ago for pivoting an armature, A A, between the two pole-pieces, P P, attached to the ends of the core, C C, of a horse-shoe electro-magnet. The particular form chosen leaves very narrow gaps in the

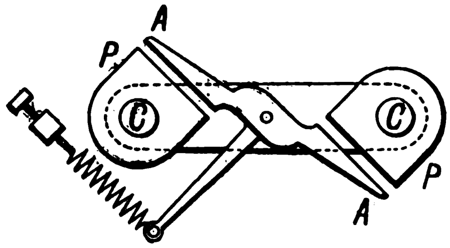

Fig. 12.

magnetic circuit, which, therefore, requires little current to magnetise it, making the arrangement very sensitive. Compare with this a device due to Waterhouse, of New York, shown in Fig. 13, who pivots one of the two cylindrical cores of the electro-magnet, furnished with a projecting tongue, A. The other core, B, is provided with a larger tongue, D, of brass or other non-magnetic metal to support the lower pivot. If A is originally turned outwards, the tendency of the magnetising current will be to turn it back into parallelism with the support D.

*Mechanisms of Bells and Indicators.*

The mechanisms of electric bells, and those of the annunciators or indicators used in conjunction with electric bells, furnish a variety of examples of devices, all of which are readily comprehended by the aid of the principle of the magnetic circuit. A number of these I have upon the table. Here are a few indicators. In some of them a pendulum is drawn on one side, and then left to swing. In another a trip lever, which carries a red disc, is latched up out of sight until the electric current comes and pulls down the latch. In another, an armature pivoted between two flat polar faces is drawn up into a position where it can better carry the magnetic lines. Here is a small electric bell of unusual sensitiveness of action. It is different in construction from the ordinary type of electric trembling bell. The electro-magnet, a horse-shoe, lies horizontally. The armature is a flat plate of iron, pierced with two holes; by these it is hung upon two brass pins which stand out like two miniature hat-pegs from the polar faces of the cores. This armature is always in contact with the electro-magnet, so that the magnetic circuit is, in one sense, always closed; but the spring attached behind keeps the armature from lying flat against the pole-faces; it only touches along its edge. It can, therefore, better the circuit by tilting upon its pins, and in this manner it

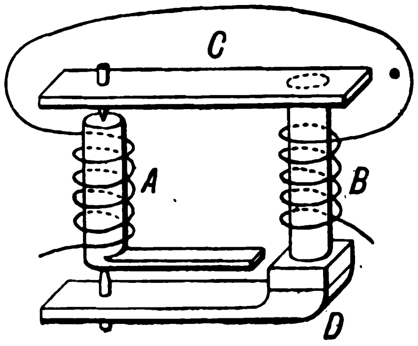

Fig. 13.

vibrates. Its great sensitiveness may be attributed to the way in which the initial position adopted aids the excitation of the magnetism.

*Polarised Mechanisms.*

There is another set of electro-magnetic mechanisms in which use is made of a permanently-magnetised steel magnet, in addition to electro-magnetic devices. One of these is illustrated by the sketch shown in Fig. 14. Here is represented an inverted horse-shoe steel magnet, its north and south poles being indicated by the letters N and S. There will be a powerful magnetic field in the space between the two limbs, where the magnetic lines pass across from one limb to the other. If a loop of copper wire is placed over one of the poles, and the electric current is sent around the loop, it will be found to be acted upon by a mechanical force tending to drag it across the magnetic lines of the field.

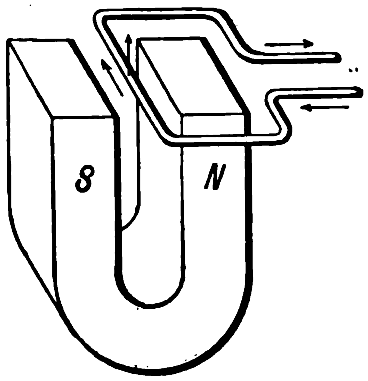

Fig. 14

In this device the direction of the motion will depend upon the sense in which the current is flowing in the loop of wire. If the sense of the flow be that indicated by the three arrows, the direction of the motion will be upward, as indicated by the fourth arrow. If the current were reversed the direction of the motion will reverse. Now, this is quite different from the action of the ordinary electro-magnet of soft iron, for in that case the core pulls at the armature in the same direction, no matter which way the current is flowing around its coils. To distinguish between the two cases it is usual to refer to those devices in which a permanent magnet comes into use as *polarised* mechanisms, whilst the ordinary electro-magnets are *non-polarised*. One result of using a polarised mechanism is to secure uni-directionality of motion in correspondence with the current. The single-acting mechanism is thus made into a double-acting mechanism, a point the possible advantage of which every engineer will at once grasp. Sturgeon, the inventor of the original electro-magnet, was himself the inventor also of a

Digitized by Google

polarised mechanism intended to be used as an electro-magnetic telegraph. It is shown in Fig. 15, and consists simply of a permanently magnetised steel compass needle placed with one pole between the poles of a soft iron horse-shoe electro-magnet. If the current is sent around the spiral coil from N to S, the left hand pole will become a north pole and the right hand pole a south pole, with the result that the north pole of the compass needle will turn to the right. On reversing the sense of the current the needle will of course turn to the left. It is strange that this invention, which Sturgeon gave to the world unpatented in 1836, was never brought into commercial use as a telegraph at a time when telegraphs were almost a monopoly in the hands of a few interested persons. Perhaps like some other unpatented inventions of which Hughes's microphone is a notable example—it was appropriated by some other inventor by judicial stretching of his patent to cover what he never dreamed of inventing.

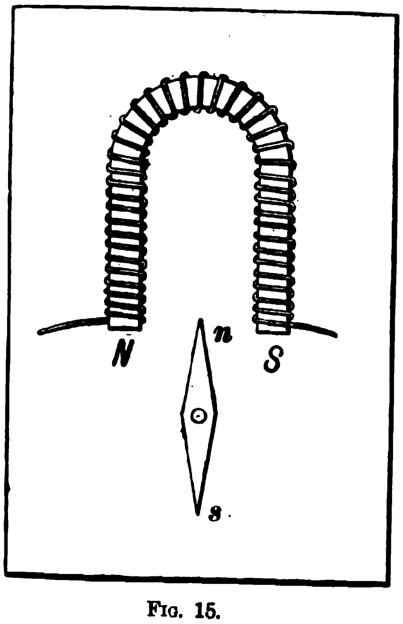

Fig. 15.

Another form of polarised mechanism is used in an electric bell upon the table, one of that species of electric bell which is worked without any battery by means of a little alternate current dynamo machine turned by a crank, and known as a "magneto-generator."

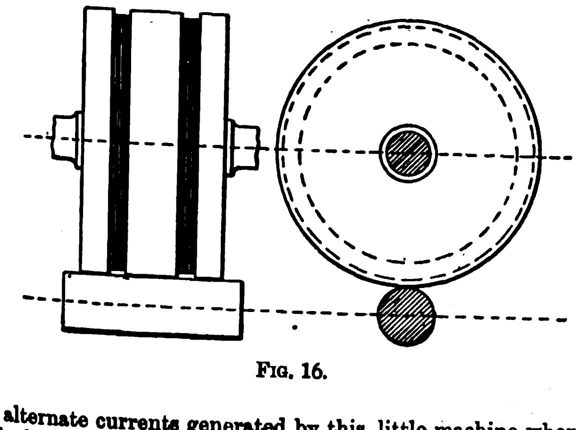

Fig. 16.

The alternate currents generated by this little machine when they reach the bell throw its polarised armature over alternately right and left, so that its rate of trembling depends on the rapidity with which the alternations succeed one another.

*Vibratory Mechanism*

The mention of electric bells suggests to me that there are numerous devices for producing a vibratory movement by electro-magnetic means. Such are to be found not only in bells, but in the automatic breaks of induction coils and of electrically-driven tuning-forks. To enter upon a discussion of these would lead me too far afield.

*Rotatory Devices and Electro-Magnetic Motors.*

Similarly, I must pass over the enticing topic of the rotatory devices used in electric moters, to one class of which, namely, those working by oblique approach, I alluded a little time back. But this class of motor is adapted only for use on a very small scale—practically only for toys. The larger motors, which, indeed, are nothing else than dynamo-machines arranged to be used in the inverse function of doing mechanical work when supplied with electric energy through a wire, are never built on this plan. In these, the rotating armature is usually a complex electro-magnet, built up symmetrically around an axis, with a core of laminated iron, and a peculiarly wound coil in which the current circulates in a manner governed by a commutator. I would that time allowed me to dwell on the electro-magnetic motor, and on the points of correspondence and of contrast between it and the steam engine. But no, your patience will not last for ever, not even till midnight. So I must dismiss the motor with the remark that so long as designers of electric motors adhered too closely to the plan of steam engines, seeking to produce first a reciprocating action, and then to convert this by a crank into a rotatory motion, so long was the electric motor a mere toy, and that the real advance came when the lines of steam-engine design were abandoned, and a true rotatory form of electro-magnetic apparatus was adopted. But, strange to say, this advance came about in the hands of inventors who were not trying to invent a motor at all, but who, in perfecting the dynamo machine for producing electric light, found themselves in possession of a far better electric motor than any that had been specially designed as such.

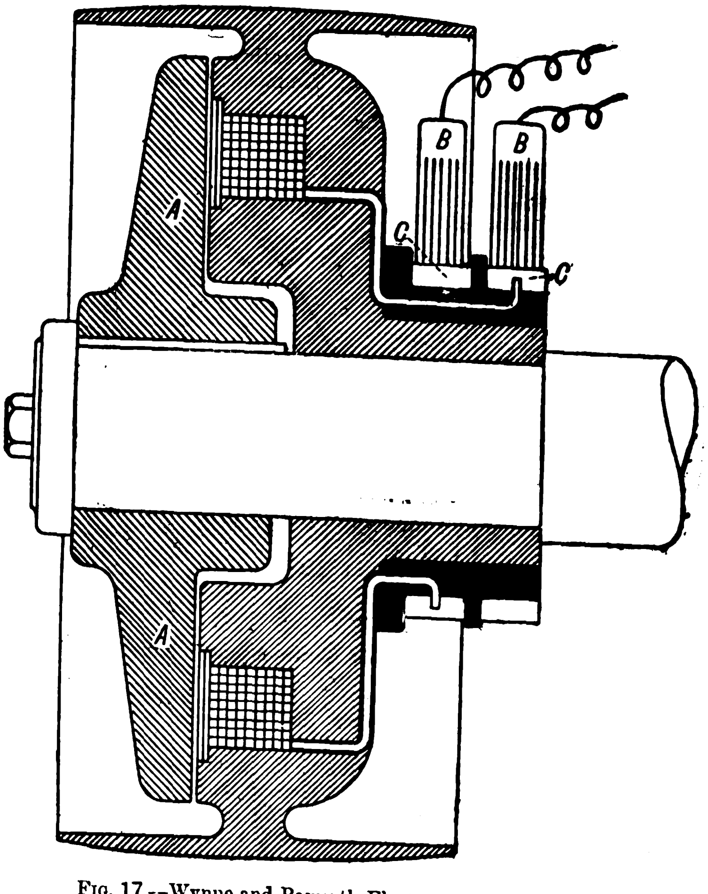

Fig. 17.—Wynne and Raworth Electro-magnetic Clutch.

*An Electro-magnetic Separator.*

Before closing this review of electro-magnetic mechanisms in general, I must, however, describe some recent devices that are worthy of the attention of the engineer. The first of these is a *separator* or *sorter* for separating pieces of iron from any non-magnetic materials. Many such have been tried in industries of very various kinds: for preventing iron particles from getting into white china clay, for sorting iron filings from brass filings, for catching nuts and nails and other such things which are liable to stray into the disintegrators used by the manufacturer of artificial guano, for selecting iron ore from mere earthy matters. The particular sorter that I have to describe to you is merely a revolving electro-magnet of a peculiar circular type, invented long ago by Prof. Weber (Fig. 16), in which the coils are wound in grooves in an iron drum. This electro-magnet is shown as being used with a cylindrical iron armature as a kind of rolling gear. In the separator in question there is no such armature; the drum merely rotates by steam in a sort of bed-plate; any iron scraps amongst the refuse that is thrown on to it being carried over to the other side, where they are removed mechanically.

Digitized by Google

*An Electro-magnetic Clutch.*

The next device that I shall allude to is an electro-magnetic clutch (Fig. 17) constructed by the Brush Electric Engineering Company, under the patents of Wynne and Raworth. This clutch consists of a peculiar form of ironclad electro-magnet, being in fact, a loose iron pulley with an unusually solid body, in the face of which a deep and broad rim has been turned to receive the coils of insulated copper wire. Opposite this, acting as the armature, is a stout disc of soft iron, A, firmly keyed upon the shaft. The electric current is conveyed in and out of the coils by means of two metal brushes, B B, shown on the right, which press against two gun-metal collars, C C, embedded in insulating fibre, and which are connected respectively to the two ends of the coil. When it is desired to throw the clutch into gear, all that is needful is to turn on the current, when the electro-magnet-pulley at once grips the iron disc with a grip that may easily be made as much as 100lb. per square inch of surface of contact, and the pulley forthwith turns solidly on the shaft. As the switch for turning on and off the electric current may be placed in any convenient position, either near or far away, it is obvious that this clutch presents many advantages over the mechanical clutches—whether friction-clutches or claw-clutches—that need some kind of striking gear to be affixed to them. For clutches in inaccessible positions on a line of shafting this device is indeed superior to anything ever previously imagined.

*An Electro-magnetic Railway Brake.*

The last contrivance that I shall describe is shown in Fig. 18. This is the electro-magnetic railway brake devised by Prof. George Forbes and Mr. J. Timmis. The ironclad electro-

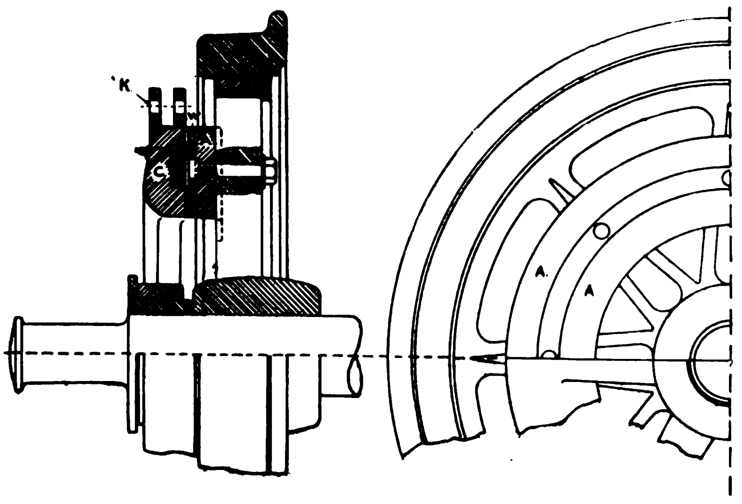

FIG. 18.—Forbes and Timmis' Electro-magnetic Railway Brake.

magnet closely resembles that just described: the core C is a ring of wrought iron, bolted securely to the axle-box by bolts passing through the holes K, and constructed with a deep groove to contain the coils. The armature A A is another ring of iron bolted to the carriage wheel. As in this case there will be much wear of the surfaces in contact, a renewable pair of iron washers, W, in two parts are interposed to serve as pole-pieces. If every wheel of every carriage of a train were provided with such a brake, these could be simultaneously thrown into action by merely turning on the electric current to the whole of them at once.

*Miscellaneous Electro-magnetic Mechanisms.*

Amongst the mechanisms that I shall not attempt to describe are those applied in electric locks, in the keyboards of electrically-worked organs, in the electric weaving machinery, which will, I believe, ere long quite supplant the Jacquard loom, and in various other industrial applications. In all this I have said nothing about the peculiar properties of the alternate current electro-magnet, a topic too vast to be entered upon here.

*Electro-magnetic Machine Tools.*

Nor have I time to do more than allude to the subject of electro-magnetic machine tools, a subject which is destined to come to the front very shortly, now that the industrial supply of electricity is spreading so quickly. Upon the table are a number of blue prints and drawings relating to the machine tools of this class—electro-magnetic drills, electro-magnetic rivetters, and the like—invented by Mr. F. J. Rowan, of Glasgow. Perhaps at some not very distant date it may be the lot of a future president of your Society to award its medal to some one of your members now present for a Paper on electro-magnetic machine tools, even as this year your medal has been awarded for one on hydraulic machine tools.

*Classification of Electro-magnetic Mechanisms.*

Now this wide topic of electro-magnetic mechanism, into which I have endeavoured to give you some insight, is one that requires to be reduced to a system. A classification I have, indeed, attempted, but it is as yet little more than an enumeration of the various forms. Such as it is I will print it with this address (see Appendix), that you may at least know in outline what has been done in the way of classification. I have already gone further, and have attempted to aid the analytical and synthetical study of the subject by a sort of notation, which, however, is not yet in a shape fit for publication. The fact is that we want some one to do for the subject of electro-magnetic mechanism what Willis and Reuleaux achieved for the subject of mechanical mechanism. It is nigh fifty years since Willis at Cambridge reduced to something like a system the subject of mechanism in general, which previously to his time had been subjected to no such systematic treatment. And it is nearly five-and-twenty years since Reuleaux, of whom your former President, Prof. Kennedy, is the exponent in this country, produced that wonderful book, "The Kinematics of Machinery," in which all possible mechanical combinations are reduced to a system of kinematical pairs and chains. I am, as yet, very far from having analysed down the topic of electro-magnetic mechanism to a consistent system; and it is quite possible that I may not succeed in doing so. Yet, whenever the man and the hour arrive that shall achieve this, there will have been achieved a work of no little importance. For the systematisation of knowledge is a work that brings in its own abundant reward in the fact that it always renders further practical advances possible in the not distant future.

APPENDIX.

*Enumeration of Electro-magnetic Mechanisms.*

I. *Electro-magnets*—
- A. Fixed coil and core; moving armature.
  1. Short compact magnetic circuit, for traction in contact.
  2. Elongated circuit and heavier coil, for attraction at distance.
  3. Special forms: Iron-clad, club-footed, laminated, consequent, multipolar, &c.
- B. Fixed tubular coil and moving plunger.
  1. Plunger longer than coil.
  2. Plunger shorter than coil.
  3. Special forms of plunger, coned, laminated, &c.
  4. Coil constructed in sections for successive action.
- C. Intermediate forms.
- D. Fixed tubular coil and movable coil.

II. *Electro-magnets with Opposing Forces*—
1. Counterpoise springs.
2. Counterpoise weights.

III. *Equalisers for Electro-magnets*—
1. Electrical equalisers.
2. Set-up springs.
3. Rocking levers.
4. Linkage movements.
5. Cam equalisers with shaped polar faces.

IV. *Electro-magnetic Cams.* Devices depending on the lateral approach of a shaped polar surface.

V. *Electro-magnetic Linkages.* Devices depending upon the mutual interaction of two or more separate electro-magnets.

VI. *Apparatus Depending on Electro-magnetic Repulsion*—
1. Mutual repulsion of parallel cores.
2. Elongation of jointed or tubular cores.

VII. *Polarised Electro-magnetic Devices*—
1. Electro-magnet with parallel polarised armature.
2. Electro-magnet with transverse polarised armature.
3. Coil with polarised plunger.
4. Polarised electro-magnet with counterpoise spring (Hughes magnet)

VIII. *Electro-magnetic Vibrators*—
- A. Non-polarised.
  1. Break-circuit.
  2. Short-circuit.
  3. Differentially-wound.

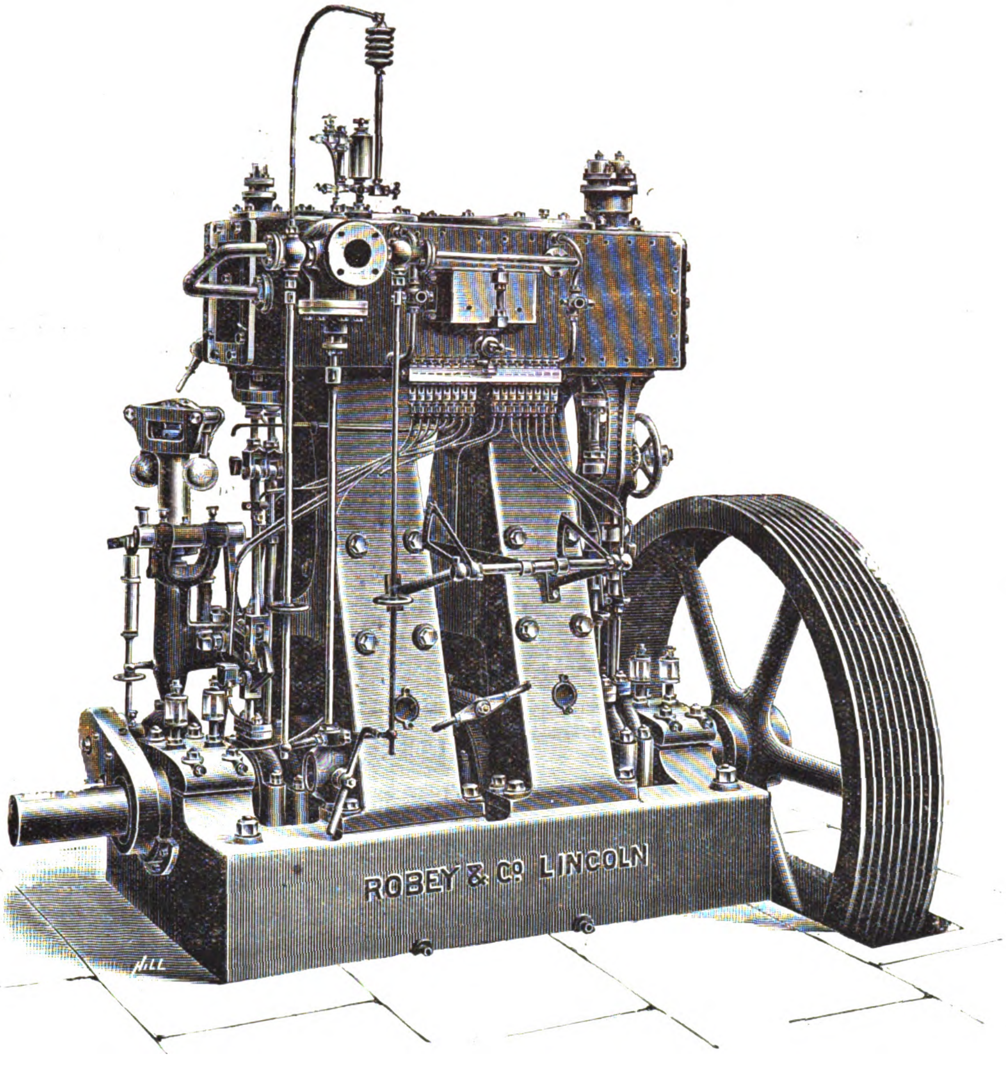
2. Shading of pole by copper screen.
3. Vertical rotation of magnetic field by two currents at angle in different phases.



High-speed Compound Engine.

## ROBEY AND COMPANY'S HIGH-SPEED COMPOUND ENGINE.

The engine shown in the accompanying illustration has been made for the Newcastle-on-Tyne Electric Supply Company, and is used to drive a 37½ unit Mordey Victoria alternator developing 70 to 75 horse-power at 200 revolutions per minute. The high-pressure cylinder is 11in. diameter, and the low pressure is 18in., with a 12in. stroke. The shaft, which is 6in. diameter, is carried in three bearings of ample dimensions, lubricated, together with all other moving parts, by sight feeds supplied from a single oil-box fitted with a gauge. The big ends of the connecting rods are provided with centrifugal oilers, and the main standards prevent oil being flung from the cranks. The frame is very massive, and the balancing of the parts together with proper setting of the valves enable the engine to run without vibration at a high speed. All parts are easily accessible, and the handles of the various valves and levers, including the drain cocks and governor adjustment, are so arranged that they can all be manipulated from one point. The link expansion is automatically governed by a Richardson governor which permits only 2 per cent. variation of speed between full load and light running. This engine is used for the day lighting as well as in conjunction with three other engines of 200 horse-power by the same makers.

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**TUESDAY, January 13th.**

INSTITUTION OF CIVIL ENGINEERS.

*8 p.m.* Paper to be read: "Auxiliary Engines in connection with the Modern Marine Engine," by W. H. ALLEN, A.M.I.C.E. Reception at 9 p.m.

**WEDNESDAY. January 14th.**

SOCIETY OF ARTS.

*8 p.m.* Ordinary Meeting. Paper to be read: "Steam Life-boats," by J. F. GREEN.

**THURSDAY, January 15th.**

INSTITUTION OF ELECTRICAL ENGINEERS.

*8 p.m.* General Meeting. Presidential Address, by WILLIAM CROOKES, F.R.S.

**FRIDAY, January 16th.**

PHYSICAL SOCIETY.

*5.30 p.m.* Papers to be read: "Photo Electricity," by Prof. G. W. MINCHIN, M.A.; "A Lecture Room Method of Determining 'g,' by Prof. BARRETT, B.A.; "On the Change in the Absorption Spectrum of Cobalt Glass produced by Heat," by Sir JOHN CONROY, Bart., M.A.

INSTITUTION OF CIVIL ENGINEERS.

*7.30 p.m.* Students' Meeting. Paper to be read: "On a Survey of the Bed of Sutton Pool, Plymouth," by R. G. HANSFORD WORTH, Stud. Inst. C.E.

# The Electrician.

**Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.**
**Editorial, Publishing, and Printing Offices:**
**SALISBURY COURT, FLEET ST., LONDON, E.C.**
*Telephone No.* 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

*All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher,* "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*" *All other letters to be addressed to the Editor.*

*All letters intended for insertion in* "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

*New Volumes of* "THE ELECTRICIAN" *commence in May and November.*

## SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

| | 3 months. s. d. | 6 months. s. d. | 12 months. s. d. |
|---|---|---|---|
| For the United Kingdom | 5 0 | 10 0 | 19 6 |
| For Foreign Parts and Colonies:— | | | |
| Within Postal Union | 6 6 | 12 6 | 24 0 |
| Aden Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar | 7 6 | 14 6 | 28 0 |

## TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

*Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xvii.) are accepted up to 4 p.m. on Thursday.*

## TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

## "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

*Early in each year is issued* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consisted of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

*The 1891 Edition is now actively preparing, and Subscription and Advertisement Orders, New Names, Corrections, &c., can be received.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

*All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of* "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

## SPECIAL NOTICE.

**With the Next Number of "THE ELECTRICIAN" we shall issue a fine Steel-Plate Portrait of Mr. WILLIAM CROOKES, F.R.S.**

## ALTERNATING CURRENTS AND MATHEMATICS.

That branch of electrical engineering which deals with alternating currents presents some difficulties to every non-mathematical engineer and to many students. To any of the latter who are still engaged in the lecture-room and laboratory, it all comes in the day's work, and while they cannot shirk it like the professional man, who says that he prefers continuous currents, they should realise that they have opportunities for mastering the subject which he never had. In alternating work, Ohm's law fails to be a trusty guide volts and amperes can no longer be simply multiplied together to give the watts, nor can they be measured by some of the well tried instruments. Iron wire resistances do not behave with their old regularity, and are sometimes replaced by noisy choking coils about which no text-book gives information. In alternating current work we meet with various quantities which, though they always exist, are generally negligible, since they only come in play at the make and break, or the change of strength of the current. If we look for some plain rule such as that which connects a simple current with volts and ohms we find but little comfort in the admirable equation which would have formed the last line of page 259 in our issue of January 2nd, had the column been wide enough; and whose beauty is considerably marred by being cut in two portions. This formula starts bravely, but seems to expire with a sigh, and then begins again with a minus sign, and contains the expressions $G_0$ and $H_0$ which have not been referred to before. On turning to the next page, some of the symbols are pleasantly expanded, but the $G_0$ and the $H_0$ about which the careful reader has been wondering, are found to be merely "certain complicated functions of the inductances, resistances, and capacity,"

"and $\theta$ is likewise a function of all these quantities." But why, it may be asked, should this equation be particularly comforting to the engineer who contemplates a journey into this region of ohmic anarchy, and who only dimly recognises $\sqrt{R^2+p^2 L^2}$ as an obscure obstruction called "impedance." Dr. FLEMING's opinion of its value is the answer, "this equation may be looked upon as a kind of glorified Ohm's law," by means of which all troublesome questions, whether treating of unexpected rise of pressure in FERRANTI mains, or retardation of signalling in cables, or difficulties in telephony, or, indeed, the behaviour of any apparatus joined by any kind of conductor, may be duly solved.

This formula is, we understand, the outcome of an enormous amount of work of the most arduous nature, and has entailed an expenditure of labour comparable indeed with the potential value of the result, but which at present will not be readily appreciated by everybody. It not unfrequently happens that the mathematician has not the good fortune to come into contact with practical work. He must therefore leave to others who have to use his figures the finishing touches which they need; and few will welcome more than he the practical realizations of his predictions. One reason why the busy engineer does not properly value such work as this is, that it is not left by the able analyst in a fit state for him to use. An equation containing one or two functions whose values have not been calculated is useless, and he demands a table of the constants, or clear directions for ascertaining them. To a mathematician, the formula is generally a finished piece of work, but to the engineer it is a tool. To make the tool practically useful it must be sharpened. It is the custom among tool-makers to sell their wares unground, and mathematicians not infrequently turn out their formulæ in an equally unfinished state.

Under these circumstances it is not surprising if certain electrical engineers in good practice should stoutly set their faces against this new-fangled system, and though they may not fully appreciate the demolition of Dr. FRANKLAND's complicated theory of sub-sulphates by Dr. GLADSTONE and Mr. HIBBERT, they give their adhesion to continuous currents and storage batteries, and decline to enter into any dealings with the alternating demon, merely because they are alarmed at the bristling equations and horrid formulæ.

There may exist, though we have not yet met him, a rule-of-thumb alternate-current engineer. We know plenty of continuous-current men who manage to get along pretty well although they have a remarkably small acquaintance with any kind of science or mathematics, and who do their work well, and we may say conscientiously, though it may be thought that they have no business to attempt to do work which they cannot properly understand. But is there, indeed, anything that anybody may be said to properly understand? The hope has been expressed that the spread of the alternating-current system will raise the standard of education of the electrical engineer. But some people may feel discouraged, because they know that they have neither inclination nor aptitude for such mathematical work as is to be found, for example, in the recent contributions of Mr. GLAZEBROOK, Mr. SWINBURNE, and Dr. FLEMING, and that, as the teaching of useful geometry is as yet almost unknown in this country, they cannot even appreciate the graphical methods with which Mr. KAPP and Mr. BLAKESLEY have treated the same subject. To these we would offer encouragement by quoting a passage from an essay by J. HINTON, on "The Two Sides of a Thing:" The immense number of new facts which science accumulates year by year, the unanticipated results which it meets at every turn. . . All these seem as if they would merely overwhelm the mind, and leave it utterly lost amid the wages of its own wealth. And they would assuredly have this effect if there were not another process continually going on in science, at the same time, with this multiplication of its materials and extension of its view. This process is the simplification of the ideas, around which these ever-multiplying facts are grouped. . . So constant, and, indeed, inevitable is this process, that it is no exaggeration to say that when a branch of science has attained a certain perfection, the more facts and details it contains, the easier it will be to understand. The multiplied and almost unmeaning series of phenomena receive expression in a law which most probably is self-evident, or at any rate is capable of being easily apprehended."

There are different opinions as to which of two methods is the more easy. Some persons prefer long multiplication to logarithms because they are familiar with the one and have not learned the other. Logarithms, as generally taught, are perfectly useless, and there are hundreds of school-boys who can define what a logarithm is, and can explain characteristics and mantissæ, and could calculate a simple log or two, but who have never seen a table of logarithms, and who are utterly unable to use one quickly enough for ordinary purposes. On the other hand, the majority of engineers who use them in daily work have forgotten, if they ever knew what logarithms really are, and not one in a hundred could explain how Napier arrived at the base $e$, 2·71828, or what he did with it when he got it. The common method of teaching logarithms is enough to make a student think that it is a difficult and clumsy method of multiplication. Similarly with higher mathematics. Their introduction does not really make the problem more difficult, but they make easy that which cannot be done by lower mathematics, except occasionally by lengthy roundabout ways. Algebra is a capital thing when it can be used, and geometry, in our opinion, is still better, but many problems cannot be solved by algebra alone, and geometry, as we have said, is in far too crude a state at present to be of much assistance. But before attempting any of the problems to which we refer, it is first absolutely necessary to have a clear conception of the meaning of the terms employed, and of the quantities which they denote.

We recommend to the student and to the aforesaid engineer the clear explanation of the quantity known as a time-constant in connection with Fig. 3, in Mr. KENNELLY's Paper. The expression, like those of time integral and line integral is one that falls easily from a mathematician, and unlike the use of a reflecting galvanometer for lecture purposes, is more impressive than convincing. To anyone who is not only thoroughly familiar with mathematical language, but accustomed to think of simple phenomena in a mathematical manner, to speak of the time integral of the charging current of an accumulator may be very natural. Such an one would probably condemn the expression ampere-hour as being unscientific, but at the worst it is tautological. If a real knowledge of alternate current phenomena is to spread among practical engineers, and if a number of theorists who alone can master their principles are not to spring up, it is necessary that the explanation of their development should be treated in the simple manner of Mr. KENNELLY's Paper.

In Mr. KENNELLY's present article we would observe that the symbol H, which he suggests for a "henry," too closely resembles **H**, which has been well nigh unanimously adopted as denoting magnetising force, having superseded the $\mathfrak{H}$ which was used by MAXWELL and others, and that the symbol L is always used in this country for inductance, or self-induction as it was called before Mr. HEAVISIDE gave us the shorter

Digitized by Google

and more general name. Some months ago Prof. Ayrton rose at a meeting and held up a coil of wire and asked who could express its self-induction in terms of a length. The idea was then comparatively new, nor have secohms and quadrants since that date been often heard of outside the lecture rooms and mathematical papers. But now that the expression is beginning to come into use under the name "henry," the time has come for it to take its place among ohms and volts. Engineers who have no time for higher mathematics, do not willingly accept expressions of which they cannot grasp the common-sense meaning, and Mr. Kennelly supplies this want by a large number of instances from practice of the value of the inductance in "henrys" of various well-known instruments. To facilitate a more common acquaintance with the "henry," we have extracted these values and have placed them in our Notes column. Mr. Kennelly is inclined to think that because millihenrys are more frequently to be found in practice than whole henrys, the henry should be the thousandth of an earth quadrant; but we are glad to see that in spite of this suggestion, he respects the resolution of the Paris Congress that the practical unit should be a thousandth million centimetres, and the resolution of the American Institute which has adopted that length under the name "henry."

## ELECTRICAL DISTRIBUTION BY TRANSFORMERS FROM CENTRAL AND ECCENTRIC STATIONS.*

BY DR. J. A. FLEMING, M.A.

*(Continued from page 257.)*

### Station Appliances in the Thomson-Houston System.

*Earth Detector.*—Every switch-board is provided with an earth-detector, by means of which an "earth" or "ground" may be detected if it exists on the primary mains. This apparatus is shown in Fig. 19. It consists of a small transformer, mounted on a board with a lamp on its secondary circuit and a two-way switch. One end of the primary wire of this small transformer is permanently connected "to earth," and the other primary terminal can be connected by the switch to one or other of the two primary mains at pleasure. If an earth exists on one side of the main primary circuit then when the testing transformer has its one pole put on to the other main, the lamp in its secondary circuit will light up, because the current finds its way across the earth and flows through the primary coil of the testing transformer. The lighting of the lamp when the switch has one position or the other not only indicates a "ground," but shows which primary main it is on, provided that the fault is of sufficient magnitude to let out primary current enough to operate the lamp on the secondary of the testing transformer.

*Station Transformers.*—On the switchboard is also mounted a transformer which provides current for lamps to light the switchboard, and also by connection with a voltmeter, enables the primary pressure in the station to be measured.

*Lightning Arrestors.*—All overhead primary circuits are provided with lightning arrestors, both at the station end of the line and at the transformers. The principle of these instruments, of which the station lightning arrestor is shown in perspective in Fig. 20, is the same as that of the well-known Thomson-Houston lightning arrestor which has been so long and successfully used in connection with the arc-light system of the Thomson-Houston Company. This arc-circuit lightning arrestor is shown in Fig. 21, and consists of an electro-magnet, the coils of which are in series with arc-light circuit. In part of the poles of this magnet, but well insulated from them, are a pair of curved metallic horns.* One of these horns is in connection with the line and the other in connection with the earth. If a lighting discharge strikes the line, the inductance of the electro-magnet blocks the path of the discharge, and it leaps across the air space between the horns and goes to earth. In doing this, it would start an arc between the horns, were it not for the fact that a strong magnetic field is produced by the electromagnet in this air space, the lines of force of which are perpendicular to the path of the discharge. The arc is, therefore, pushed forward along the curved horns, and finally blown out or extinguished. This highly ingenious apparatus stands guard over the arc-light dynamo; and, by placing one on each end of the arc line, the dynamo and switchboard is effectually protected from discharge of lightning. Quite the same principle is applied in the station and transformer lightning guards shown in Figs. 20 and 22. The connections of the transformer guard are shown in Fig. 22. The two primary wires proceeding to a transformer enter the lightning protector at the terminals *a b*, and are connected with the transformer through the pipe *c*. To each of the terminals *a* and *b* is connected one end of the coil of an electro-magnet *d*, the other

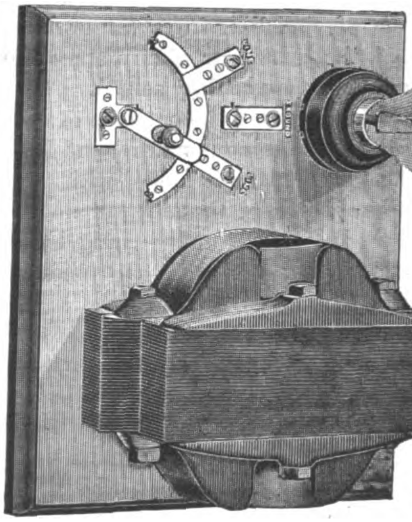

Fig. 19.—Ground Detector.

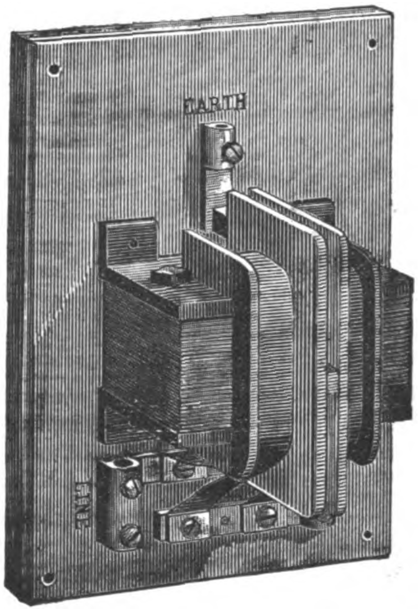

Fig. 20.—Station Lightning Arrester.

* All rights are reserved.

* For the use of this block (Fig. 21) the writer is indebted to Messrs. Laing, Wharton, and Down, and he takes the opportunity at the same time of acknowledging the kindness of Mr. J. W. Kirkland, of the Thomson-Houston Electric Light Company, in the United States, in furnishing, by permission of Prof. Elihu Thomson, sketches and detailed information on the Thomson-Houston system, which has rendered it possible to make the above descriptions much more complete than they would otherwise have been.

Digitized by Google

end of which is attached to a terminal placed near to a metal plate connected to earth. If a lightning discharge strikes the line it could cause an arc to start between the earth plate and each of the terminals of the electro-magnet coils near it. These magnets are, however, so arranged that the magnetic field created by the current then started through them will blow out the arc and stop the discharge. All transformers which are fed from overhead primary lines are protected in this manner.

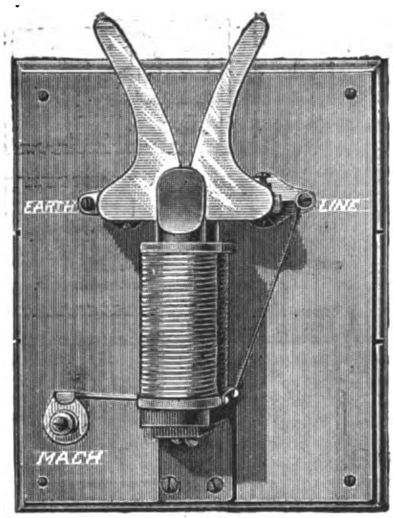

Fig. 21.—Thomson-Houston Arc-Line Lightning Protector.

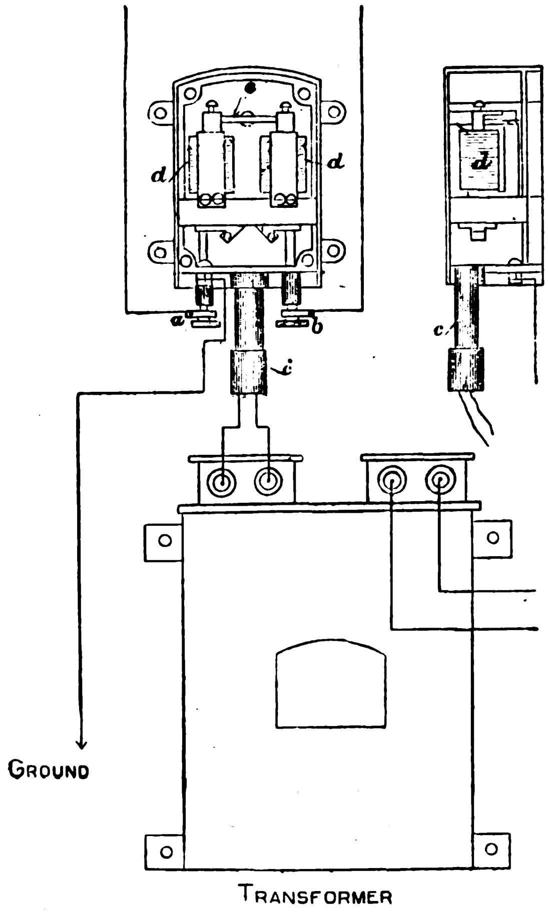

Fig. 22.—Connections of Transformer Lightning Arrestor.

*Distribution System.*—A very large portion of the transformer lighting of the Thomson-Houston Company in the United States is carried on by means of overhead or aerial primary lines. The usual working pressure on the primary circuits is 1,000 volts. In setting out these lines several main primary lines are run to iron feeder boxes (*see* Fig. 23) and from these boxes distribution primary lines are run to groups of transformers. Fuse wires or cut-outs are inserted in the feeder boxes. The transformers are placed in the buildings or are attached to the external walls of buildings, and these transformers are enclosed in cast-iron boxes which have weather, tight lids at both ends covering receptacles in which are placed the primary and secondary fuse wires of the transformers. The secondary fuse wires are generally mounted on a porcelain base and the primary on an ebonite slab. A special switch permits the transformer to be cut out of circuit whilst changing the fuses.

A general plan of an installation of alternating current apparatus is shown in Fig. 24. Starting from the station the wiring is as follows:—

The primary lines, protected by station lightning arrestors, are run from the dynamo to the centres of distribution where feeder boxes containing the necessary safety fuses are interposed, and from which run the mains for the supply of the transformers and lamps.

Before the current for any group of lamps is taken to the transformer, it passes through a junction box, from which the lines lead directly to the primary connections of the transformer. To the secondaries of the transformers, the wires for the direct supply of the lamps are attached. Before the current reaches the lamps it passes a double pole cut-out box provided with safety fuses and the automatic protection device.

In every installation of alternating current apparatus, use is made of transformer lightning arrestors, connected as shown in the diagram. Each feeder box has a sliding glass cover, which

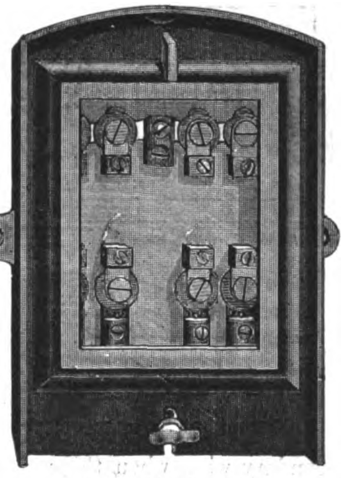

Fig. 23.—Feeder Box.

can be easily removed to replace or change fuses, and permits of a ready examination of the interior. The connections are so arranged that the box may be cut completely out of circuit during such changes.

The Thomson-Houston Electric Company, in all installations of alternating current apparatus for incandescent lighting, employs the Thomson Protective Device (shown in Fig. 25). It is a simple but effective appliance for removing the possibility of accident which might arise from contact with the secondary circuit.

There are three conditions which must be simultaneously satisfied before this possibility can be said to exist.

1. There must be a ground on the primary wires.
2. There must be a contact between the primary and secondary coil in the transformer.
3. The person must be in contact with the secondary and with the earth at the same time.

The fulfilment of the first of the above conditions is of not uncommon occurrence, but the presence of a ground can be easily detected, and means can be at once taken to remedy the trouble.

The second condition is met with seldom, and is only liable to occur when transformers are injured or subjected to rough usage in shipment.

The remoteness of liability to accident is quite apparent when it is remembered that these conditions must be simultaneously satisfied, and even then the extent of the injury

Digitized by Google

depends upon the relative position of the contacts with reference to the two primaries.

As the fulfilment of the above conditions is, of course, not beyond the range of possibility, the device herewith described has been designed to prevent any injury resulting from a contact with the secondary wires when these requirements are fulfilled. It consists of three base terminals, to the central one of which is rigidly attached a flat brass spring pressing against the two outside terminals, but normally held out of contact with them by slips of Thomson paper film. This paper film is very carefully prepared so that it readily withstands the pressure of the spring, but is instantly ruptured when the first and second conditions, mentioned above, are satisfied. To the central terminal is attached, by means of a binding screw, a wire connected with the earth. To the outside terminals the secondaries are led directly from the transformer. The paper film is perfectly insulating for the pressure of the secondary current, but if the difference of potential between the earth, with which the brass spring is in contact, and either one of the terminals, to which the secondaries are attached, should rise beyond the normal pressure, the paper film is at once punctured. This results in short-circuiting the secondary, which causes the primary fuse to blow, thereby cutting out the entire circuit.

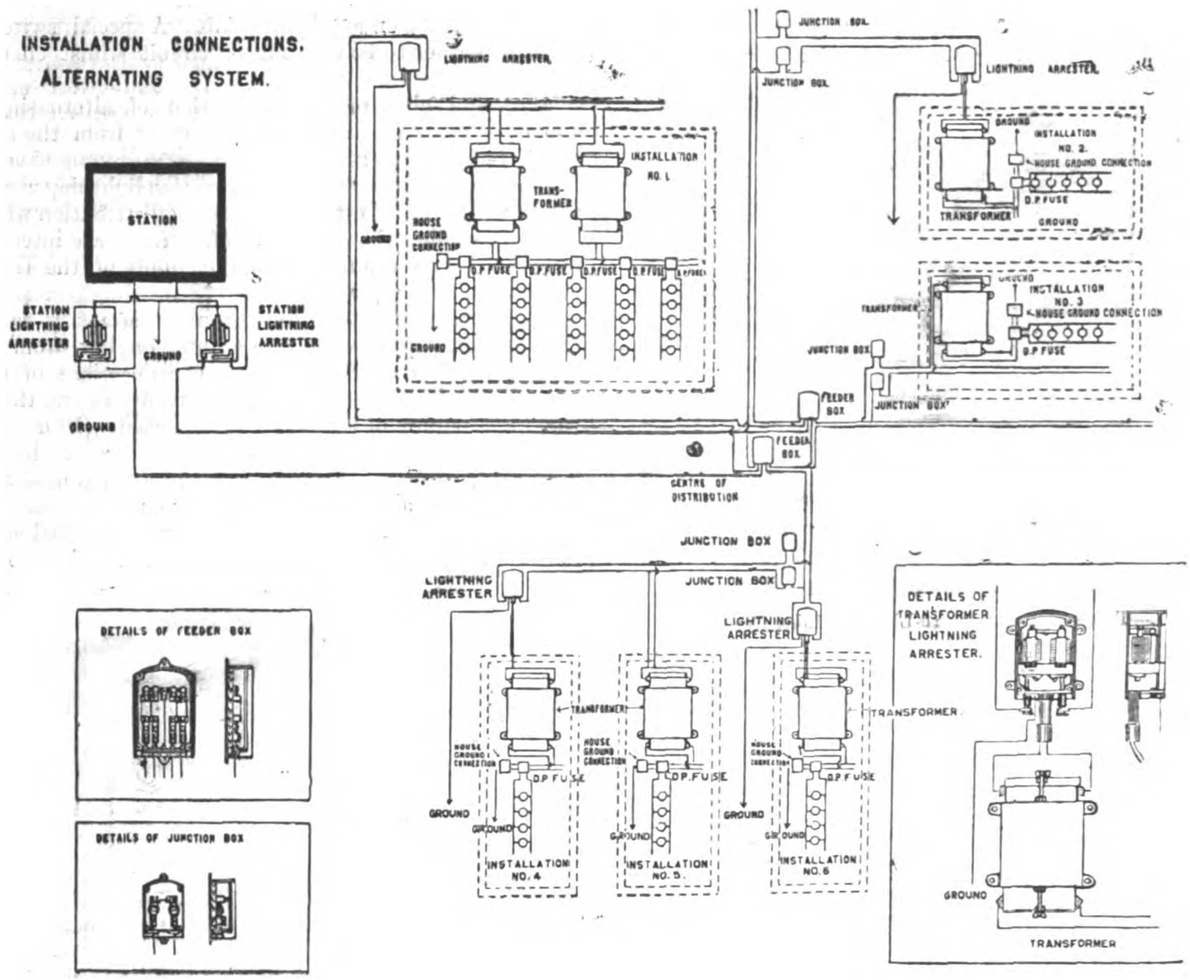

Fig. 24.

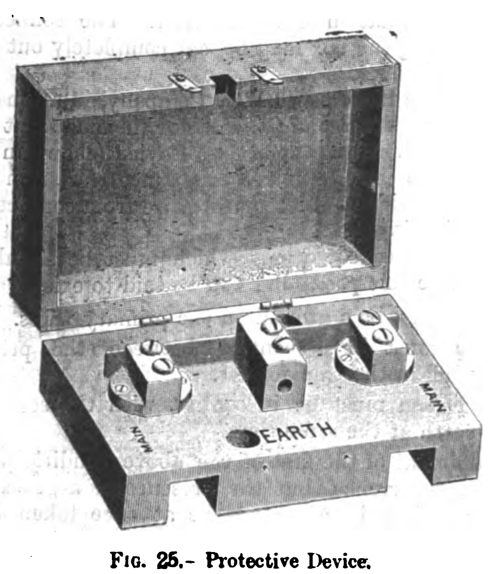

Fig. 25.- Protective Device.

(*To be continued.*)

## ON THE MEASUREMENT OF ELECTRO-MAGNETIC RADIATION.*

BY C. V. BOYS, F.R.S., A. E. BRISCOE, AND W. WATSON, B.SC.

At the time that Mr. Gregory described and exhibited his "Electric Radiation Meter" †, which indicated and measured electro-magnetic radiation by the increase in length of a fine platinum wire stretched in a glass tube in consequence of the heat developed by the induced currents within it, one of us expressed the view that it would be interesting to confirm by some independent method the conclusion that the wire was lengthened by heat, as it was not absolutely certain, though exceedingly probable, that the increase in length might not be apparent only and not real.

The following is an account of experiments made by two independent methods, with the view of finding whether the expansion observed by Mr. Gregory was such as might be expected from the induced currents.

* From the *Phil. Mag.*, communicated by the Physical Society; read June 20, 1890.

† *Phil. Mag.*, January, 1890; *Electrician*, Vol. XXIV., p. 16.

Digitized by Google

FIRST METHOD.

Imagine two straight wires parallel and near together, but not touching one another or any conductor. Let them be placed parallel to and at a convenient distance from a cylindrical rod of the same length as either of the wires. Then, if electrical oscillations are started in this rod by any well-known method, the two wires will act as resonators, and induced oscillations will occur in them, not necessarily in absolutely the opposite phase to the oscillations in the primary, but at any rate in the same phase in the two wires, so that the electricity in each will surge up and down at the same time. If, then, the ordinary theories of electro-dynamic and electrostatic action apply in the present case, which may be true or may not, then the currents going up together and down together will attract one another, while the charges resting chiefly at the two ends, being at one moment + above and − below, and at the next moment reversed, will repel one another. Owing to the harmonic distributions of the current and the charges, the electro-dynamic attraction will be mainly in the middle parts, while the electrostatic repulsion will be mainly at the two ends. Further, both these distributions vary harmonically with the time, and are a quarter-period removed from one another; but the integral effect of each is equivalent to a steady force, and the quarter-period difference of phase has no influence as far as forces are concerned.

In order to realise what these forces are, and what are the relations between them, it will be necessary to consider them separately.

(1) *Electro-dynamic Attraction.*—Let the wires be supposed to be very close together, so that the force felt by any element is almost entirely due to those elements of the other wire which are so close to it that the variation of the current strength in those elements along the wire is inconsiderable. Now, if the distance apart is $d$,

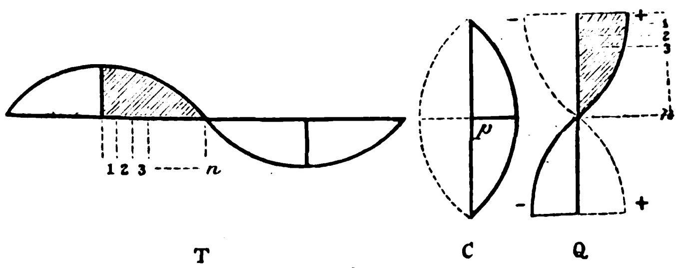

FIG. 1.

if $c$ is the strength of the current at any moment (measured electro dynamically), and if $l$ is the length of the element, the force exerted by the other wire on this element will be $2\frac{c^2 l}{d}$ dynes. But as the current at any point varies harmonically with the time, the average force will be necessarily half the maximum force; therefore the average force on the centre elements will be $\frac{c^2 l}{d}$, if $c$ is the maximum current at the centre.

Since, also, the current varies harmonically along the wire, the average force per unit length over the whole wire will be half that at the centre; so that the attraction between the wires will be $\frac{c^2 L}{2d}$, where L is the whole length of the wire.

(2) *Electrostatic Repulsion.*—In the same way, if $q$ is the quantity of electricity (measured electrostatically) on unit length at any part of the wire, the force of repulsion upon an element at any moment will be $2\frac{q^2 l}{d}$, the average force on this element will be $\frac{q^2 l}{d}$, and the total repulsion between the wires will be $\frac{q^2 L}{2d}$.

Now to find the relation between these it is necessary to remember that the wires are resonators; that is, the oscillations follow the natural period and are not forced. Also that the total quantity of electricity on one half of the wire is the integral of the current that has passed the middle point. Although there is no difficulty in finding the relation between the attraction and repulsion, the following graphic method may be worth giving. In order to simplify matters, the resonator will at first be supposed of such a length that the oscillations occur at the rate of one a second, *i.e.*, it will be supposed to be $\frac{1}{2}$ of $3 \times 10^{10}$ centim. long; also the maximum current at the centre will be supposed unity. Now let the vertical line in C (Fig. 1) represent the wire, and the distance of the harmonic curve from it at any point the strength of the current at that point when it is at a maximum.

In the same way, let the distance of the harmonic curve in Q from the wire at any point represent the charge at that point a quarter-period later, at which time it is at a maximum; then the total quantity on one end, represented by the shaded area, is the integral of the current which has passed the middle point $p$. Now this current varies harmonically with the time, as shown in the time-diagram T. This is divided into four equal parts. Thus the first represents (say) an upward current rising from zero to its maximum; this just neutralises the previously charged wire. Then, in the second period, the continuation of the current produces an equal and opposite charge, which is a maximum when the current has become zero. In the third period, the current in the opposite direction has again neutralised the charges by the time that it is a maximum; and in the fourth period, it charges the upper end negatively and has ceased to flow when the negative charge is a maximum.

Now divide the second period of the time-diagram of current T, into $n$ ($=\frac{1}{4}$ of $3 \times 10^{10}$) elements, and the upper half of the wire in the quantity-diagram, Q, into the same number of equal parts, which will therefore each be one centimetre long. Now, since the total quantity of electricity represented by the shaded part in Q is equal to the time-integral of the current which is represented by the shaded part in diagram T; and since, also, each of these is bounded by a quarter period of a sine curve, and is divided into an equal number of elements, it is clear that each space-element in Q, 1, 2, 3,......$n$, must equal the corresponding time-element in T; or, in words, though the quantity of electricity that has passed the point $p$ in the first element of time is spread over the upper half of the wire in Q, and so on, yetat the $n$th element we may consider that that which passed during the first element of time is stored on the element 1; that which passed during the second element of time is stored on the element 2, and so on. Now, since the current-strength in the first element of time is 1, and since this element of time has been made equal to $1/(\frac{1}{4} \times 10^{10})$ second, the quantity of electricity on the end centimetre of wire is $1/(\frac{1}{4} \times 10^{10})$ electro-dynamic unit, or 1 electrostatic unit. This will be repelled by the wire opposite with the same force as that with which the current in the centre element of one wire will be attracted by that in the other wire, both when each is at a maximum and through all the harmonic variations. In the same way, the next element near the end in Q will correspond to the next element near the middle in C, and so on over the whole length of each; and so, since the electro-dynamic attraction over every element in time and space is equal to the electrostatic repulsion in the corresponding element, removed both in time and space by a quarter-period, the total force due to one is equal to the total force due to the other. If any other length of wire is taken, and of course its corresponding period, since the number or length of the elements in both T and Q must vary together, the same result will follow; and if any other strength of maximum current is taken, the attractions and repulsions will be changed to an equal extent, and therefore, if two straight wires are placed so close together that the distance between them is very small compared to their length, they will, when their natural electrical oscillations are induced in them, on the whole neither attract nor repel one another.

It follows from this that, if the oscillations be forced and made too slow, the accumulation of charge on the ends will be greater for a given maximum current than it would be if the period were natural, and therefore the repulsion should overpower the attraction. In the same way, with too rapid vibrations the attraction should overbalance the repulsion. Also since, if the wires are not close together, the electrostatic repulsion will have fallen away in a higher ratio than the electro-dynamic attraction, it would appear that resonators which balance when close should attract one another when at a distance, or that resonators subject to forced oscillations which repel when near might attract at a distance.

Prof. Fitzgerald, when the above theory of the mutual action of resonators was put to him, at once suggested that if the molecules of a body were subject to electrical oscillations it would be possible to imagine a physical cause for their supposed attraction when far, and repulsion when close.

In order to test the matter experimentally, the wires were made of a cranked form, as shown in Fig. 2, so that the ends were on one side of a vertical axis (dotted), and the middle part on the other side. Then, if one is held close to the other, and if the second one is free to turn about the vertical axis, the attraction of the centre and the repulsion of the ends should conspire to produce rotation in the same direction.*

* It may be worth mentioning that the invention of this method was made in a particularly vivid dream, in which I found myself at the black board in the physical lecture-room, explaining that if the two wires were close together, the currents in each would be going up and down together, and so would attract one another, and that in order to make this attraction evident, the wire should be suspended near the axis of rotation, for the reason that where quartz-fibres can be employed there is a greater gain owing to the reduction of moment of inertia than loss by reduction of statical moment. I did not in the dream see that the charges should repel, or the necessity for the cranked form of wire. I may say that this was after Mr. Gregory had described his instrument, but the idea of looking for mutual attraction between a pair of resonators had not before occurred to me.—C. V. B.

The first experiment was made with a pair of copper wires each one foot long, bent so that the end parts were each 2½in., the middle part 5in., and the horizontal part 1in. This was suspended in a glass jar by a quartz fibre, so that the vertical axis of rotation was halfway between the ends and the middle portion. An ordinary galvanometer mirror was attached to the rigid glass hook from which the wire was suspended, and this could be seen through a plate-glass window in a torsion-box above the jar. The oscillator consisted of two pieces of brass tube half an inch in diameter with hemispherical ends, each 6in. long in all. This was placed in a vertical position two or three feet away from the wires, and in the plane of the suspended wire, so that it should not act directly upon it. The two parts of the oscillator were connected by very fine wires with the terminals of a Voss machine. Then it was found that when the halves of the oscillator were separated too far for a spark to pass, there was no deflection, while when they were gradually made to approach one another, no motion was visible on the scale until sparks passed, and then the motion was evident enough, the light even going in favourable cases off the scale in the right direction.

However, this was only a preliminary experiment made with materials at hand. It was clear that the material which was most suitable was that which had the highest conductivity for its density, namely, aluminium, and that only the outer surface of the wire could be efficacious, since the oscillations were at the rate of about 500,000,000 a second. Accordingly, thick aluminium wire was rolled into thin ribbon, which was then drawn through successive holes in a draw-plate until a perfect tube, cracked down one side of course, was formed.

We used resonators made of this material in the next experiments, which were made with the view of seeing whether the couple observed was due equally to the repulsion of the ends and attraction of the centre, or if one preponderated over the other. The fixed

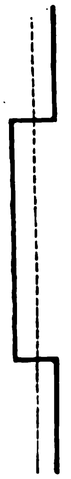

Fig. 2.—One quarter full size.

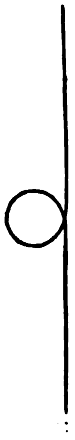

Fig. 3.

cranked resonator was then replaced by a straight one, which was held at first close and opposite to the ends of the suspended cranked resonator, when a strong repulsion was observed, as expected. It was then held in the corresponding position opposite the centre part, when, instead of the expected attraction, feeble repulsion was observed; and finally, on being placed equidistant from the two, the ends were repelled away.

Since this appeared to show that the electrostatic repulsion was much greater than the electro-dynamic attraction, we tried the following experiment, in which the electrostatic action was reduced to practically nothing. A pair of resonators were made of the form shown in Fig. 3, and one was weighted with a non-conductor and suspended so that the straight part was in the axis of rotation. The other was then held with the curl close and parallel to the curl of the other, and so that at first the current in each should go round the same way, and then in opposite ways. No action was observed in either case. When also cranked or straight resonators were entirely immersed in water no effect at all was observed.

We have given a short account of the early experiments because at first they were so completely in accord with the result of the theory put forward, though the action was more powerful than had been expected, that for a time we were deceived as to the real cause, and we wish to guard others from falling into what is after all a very obvious error. The later experiments showed either that the theory was only true as regards electrostatical repulsion, the electro-dynamic attraction of the momentary currents being *nil*, or else that the results already obtained were spurious.

We have stated that the two resonators were suspended in a glass jar, outside which the primary oscillator was placed, and that while no repulsion was observed during the gradual charging of the oscillator-ends to a higher potential than that employed with the sparks, yet the moment the sparks passed when the ends were nearer together, the suspended resonator was observed to move in the expected direction. Now if the glass jar were a conductor, the oscillator-ends might be charged to any extent and no action would be felt inside; if, on the other hand, it were a perfect insulator, then during the charging of the oscillator-ends before the spark the resonators would have induced charges in their ends which would make them repel one another. The glass jar exposed to the moisture of the air was a sufficiently good conductor, on its outer surface at any rate, to be able to screen the statical action of the charges on the oscillator-ends which were by the arrangement only slowly made to vary, and so the repulsion which might have been looked for was not observed; but the moment a spark passed in the primary, the conditions were changed. The fall of potential was instantaneous, but the screening charge on the glass surface, which the previous moment produced within the jar an effect equal and opposite to that of the charges on the oscillator-ends, was unable instantly to disappear owing to the imperfectly conducting surface of the damp glass, and thus at this moment the resonators were in the condition that they would have been in had there been suddenly developed on the oscillator-ends equal and opposite charges, but with no glass jar between. This, then, was the cause of the repulsive impulse which was observed at each spark when they followed one another at intervals. When, however, a torrent of sparks was produced, the glass surface would take up a screening charge equivalent to the mean charge on the oscillator-ends; then, when the oscillator-ends had charges either above or below the mean charge, the statical action on the resonators would be the same as that due to the excess or defect on the oscillator, so that the steady repulsion observed was due to induction alone, and had nothing whatever to do with electrical oscillations proper.

In order to perfectly screen off this induction effect, and yet leave the action of the true electrical oscillations, it was necessary to so increase the conductivity of the surface of the glass jar that it would have time to acquire a screening charge which should follow variations of potential accompanying the sparks at the rate of, say, 10 or 20 a second, and yet leave it so imperfect as to be practically an insulator to oscillations at the rate of 500,000,000 a second, which corresponded to the apparatus in use.

Prof. J. J. Thomson has shown* that the conductivity of liquids may be determined by finding what thickness of a sheet of liquid is just sufficient to prevent oscillations of a known rate from exciting a resonator on the other side, and that the thickness must be proportional to the specific resistance. For instance, he found that a layer of dilute sulphuric acid three or four millimetres thick was just opaque to oscillations at the rate of 100,000,000 a second. It would, therefore, require a greater thickness to be opaque to oscillations of 500,000,000 a second, and a very much greater thickness for water to be opaque to oscillations of this rate. A duster, therefore, soaked in water, though it might reflect some fraction of this radiation, should be practically transparent to it. Nevertheless, a wet duster would be amply sufficient to screen the action of true harmonic variation of potential of the frequency of the sparks, *i.e.*, 10 or 20 a second. As a matter of fact, these variations of potential are not simply harmonic, but since by Fourier's principle the non-harmonic periodic change is equivalent to a series of true harmonic changes at successively higher rates all superposed, the wet duster should completely screen all the lower of these components up to a certain point, and probably far enough. On wrapping up the jar with a wet duster all effect was found to cease, and the spurious character of the deflections was demonstrated. It is possible that these are not the only experiments with electrical oscillations in which a wet duster or its equivalent might be found of service.

The apparatus was then re-made with the view of obtaining very great delicacy. To make the resonators aluminium wire was rolled into ribbon of $\cdot 2 \times \cdot 001$ centim., so that each centimetre in length weighed only half a milligram. Two pieces 30 centim. long were fastened in the cranked form previously described on very light frames made by cementing to almost capillary thin glass tubes cross bars cut from microscope cover-glass, so that the ends of these cross bars held the corners of the cranked pieces of aluminium ribbon. One of these was suspended in the same apparatus by a fine quartz fibre, and all was arranged with the view of obtaining a delicacy comparable with that employed by one of us in the Cavendish experiment. It was now impossible to keep the spot of light at rest, owing mainly to air-currents in the jar set up by differences in temperature of the sides of the jar which could not be avoided in the schools, and also to the perpetual tremor. In the winter, however, the elementary laboratory on the other side of the Exhibition-road was not being used, and so everything was transferred to a small room there, where a fair degree of quiet and uniformity of temperature could be obtained. The Voss machine was replaced by a large induction-coil, which gave a greater torrent of sparks. Then, to get more energy in each spark, the primary oscillator, made of 12 millim. tube, was replaced by a pair of

* *Proc.* Roy. Soc., Vol. XLV., p. 269.

Digitized by Google

spheres 100 millim. in diameter, with small spheres on short sliding rods, between which the sparks passed. The scale was placed at a distance of 281 centim. from the mirror. Then, when the wet duster was placed round the jar and the sparks made to pass, deflections of five to 10 millim. were observed. Fearing, however, that even the wet duster failed to completely screen the induction-effects due to the rise and fall of potential of the primary, or rather some of the higher harmonics already alluded to, we soaked it in dilute sulphuric acid instead of water, so that no doubt should exist as to its sufficient conductivity to quench the sham effect while it still remained unable to stop more than a small proportion of the waves of 500,000,000 a second. With this precaution all definite movement of the spot of light ceased. It was seldom that air-currents did not cause a gentle hovering of the index a few millimetres either way, which, however, had no relation to the starting or stopping of the sparks; on one or two frosty days, however, when the temperature was very uniform, there being no fire, the spot of light was so steady that a movement of even one-tenth millim. on the scale would have been observed, but we have based our calculation on the certainty that the deflection was not one-fifth millim.

In order to make sure that this was a true negative result the duster was removed, when at once the index was driven violently off the scale, and then a Hertz resonator tuned to the oscillations of the primary was placed in the jar and surrounded by the same acid duster when the sparks in the gap were evident, showing that the proper electro-magnetic waves did penetrate into the jar as supposed.

The turning moment corresponding to a deflexion of $\frac{1}{5}$ millim. may be found from the following particulars:—

Period of oscillation of mirror and stem (oscillator removed), ·947 second.

Period of oscillation with wire ring hung on, 4·13 second.

(Wire ring 1·6 centimetre diameter outside, made of wire ·122 centimetres in diameter; mass ·4635 gramme.)

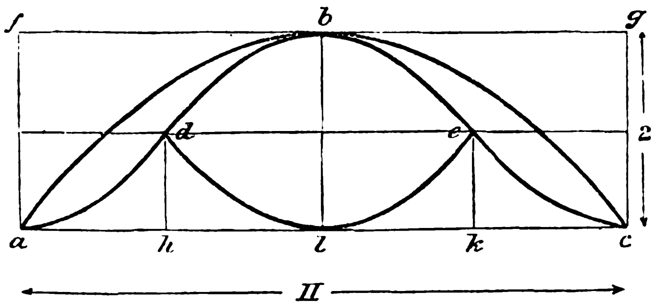

Fig. 4.

Hence couple $= 1{\cdot}1 \times 10^{-5}$ C.-G.-S. units, and average value of couple $= 3{\cdot}7 \times 10^{-7}$ C.-G.-S. units per centimetre of wire of resonator, which corresponds to a force of about $3 \times 10^{-7}$ dynes, since the distance from the axis is $1\frac{1}{4}$ centimetre. This is less than a two-hundred-millionth of the weight of a grain, or a three-thousand-millionth of the weight of a gramme.

Since the wires were only ·2 centimetre apart, this shows that, if the currents in the wires, instead of being oscillating, had been simply ordinary steady currents, those currents could not have reached the value of ·0017 C.-G.-S. electro-magnetic unit or ·0017 ampere.

Now the moment, if the theory advanced is correct, is due partly to the electrostatic repulsion and to electro-dynamic attraction which are equal to one another, but owing to the harmonic distribution of both, both in time and in position, and owing to the fact that the weaker part of each of these forces is tending to counteract the stronger part, the total average resultant force is by no means double or even equal to that due to a steady current alone of a strength equal to the actual maximum.

To find the relation it is necessary to first consider the effect of the harmonic distribution of either, say the current, along the wire. The square of this at any point is a measure of the force at that point, so that the force varies from zero at the ends to its full value in the middle, having passed its half value at the points where the wire crosses the axis of rotation.

Thus, in Fig. 4, the ordinates of the upper curve *a b c*, which is half a sine curve, represent current strength, those of the lower curve *a d b e c*, which is a complete sine curve on half the scale, but shifted vertically by the amount of its own maximum ordinate, since

$$\sin^2 a = \frac{1 - \cos 2a}{2},$$

represent the force due to the current at each point. The rectangular area *f g c a*, equal to $2\pi$, measures the total force due to a uniform current of the maximum value. The areas *a d h* and *c k e* are the forces due to the ends of the wires in the wrong direction, and these together

$$= \frac{\pi}{2} - \int_0^{\pi/2} \sin\theta \, d\theta = \frac{\pi}{2} - 1.$$

The area *h d b e k* is the force due to the middle half of the wire in the right direction, and this

$$= \frac{\pi}{2} + \int_0^{\pi/2} \sin\theta \, d\theta = \frac{\pi}{2} + 1.$$

The difference of these, which is the area *d b e l*, the balance in the right direction, and this = 2. But the force due to a current of the maximum strength over the whole length of the wire is $2\pi$, so the force in the crank conductor due to the harmonically distributed current and the opposite effect of the ends is $\frac{1}{\pi}$ × that due to uniform maximum current over the whole wire. The current is not steady, but varies harmonically with the time, so on this account the value must be halved again, but this halving is exactly balanced by the doubling which results from the fact that the electrostatic exactly equals the electro-dynamic effect.

We have seen that the force was not so great as that due to a steady uniform current of ·0017 ampere; therefore, the maximum current in the centre could not, if the oscillations continued uninterruptedly, have reached the value of $\sqrt{\pi} \times {\cdot}0017$ or ·003 amperes. Since in the most violent torrent of sparks that can be produced the time during which the oscillations last is very small compared to the interval between two sparks, it is quite possible, and even probable, that the actual current during the earlier part of each spark greatly exceeded this, but this is a superior limit to the value of the square root of the mean square of the strength of the current in the particular case.

It should be noted that two errors, each of which is numerically insignificant, have, for convenience, been made. One is the supposition that the forces on the elements near the ends of the resonators are the same as though they were continued together with the stationary wave. As a matter of fact, it is only the last few millimetres for which there is a falling off. The second error is made by supposing that the middle half of the wire is all at one distance from the axis on one side, and the two end quarters at an equal distance from the axis on the other side. As a matter of fact, the wire has to cross over, but as the two forces almost exactly balance on the small part which crosses the axis, it was not worth while to complicate the simple statement of conditions illustrated by Fig. 4 for the sake of an imaginary degree of accuracy which the nature of the observations would not justify.

*(To be continued.)*

## INDUCTANCE AND ITS PROPOSED UNIT THE HENRY.*

BY A. E. KENNELLY.

*(Concluded from page 267.)*

### Submarine Telegraphy.

**The inductance of a mirror-speaking galvanometer of the ordinary type having 2,250 ohms was found to be 3·6 henrys.**

### Telephony.

**The inductances met with in the ordinary long-distance telephone apparatus are as follows:—**

**The call bell 80 ohms and 1·4 henrys.**

**The magneto armature 550 ohms, and from 2·7 henrys with the plane of the coil in the line joining the poles, to 7·3 henrys when the iron core joins the poles, the plane of the coil being then at right angles to the magnetic flux.**

**The induction coil primary 0·28 ohm and 3·5 millihenrys.**

**Secondary 164 ohms, and 734 millihenrys.**

**The mutual induction between the coils 60 millihenrys.**

**The Bell telephone receiver 75 ohms and from 75 to 100 millihenrys. The removal of the diaphragm from an ordinary telephone of this type reduces the inductance about 35 per cent. All these inductances are to currents of a few milliamperes only. As regards the inductance of aerial line wires, it is to be regretted that measurements are not yet forthcoming, and, indeed, the experimental determination is attended with some difficulty, owing to static capacity and imperfect insulation. In the absence of direct measurements, theory indicates that the inductance of overhead copper**

wires depends upon the elevation above the ground as well as upon the diameter. In the case of iron wires as used in telegraphy, the permeability of the iron enters as an additional factor. The following table of inductances for copper wires is based upon a formula first given by Clerk Maxwell.* It is to be hoped that experimental evidence may shortly be collected corroborating these results :—

**Table** *of Inductances of Copper Ærial Line Wire, per Kilometre and Mile, for Different Diameters, and Elevations above the Ground.*:—

| Diameter of wire. | | Elevation above ground 400 cms or 13·1ft. | | Elevation above ground 700 cms or 23ft. | | Elevation above ground 1000 cms or 32·8ft. | | Elevation above ground 1300 cms or 42·7ft. | |

The inductance of iron wires, in the absence of measurements, is almost too doubtful to justify calculation, being perhaps 10 times more than the inductance of copper wires under similar conditions. The difficulty in their case lies in assigning the proper value of permeability.

### Electric Light and Power.

Dynamos and dynamo-electric machinery are, of course, generally characterised by large inductances.

The inductance of the field-magnets of a dynamo may have any value depending on the size and voltage of the machine from one henry up to 900 henrys.

The inductance of an armature may similarly vary from 20 millihenrys up to 50 henrys between brushes. One millihenry is a fair average value of the inductance of one section of an armature. Armature inductances depend not only on the strength of the measuring current, but also upon the strength of the field, and whatever influences the permeability of the core.

The inductance of an alternating transformer varies from a primary of 400 millihenrys, a secondary of one millihenry and mutually 20 millihenrys with a transformation ratio of 20, up to corresponding values, perhaps one hundred times as great.

### Apparatus. The Inductance of Ruhmkorff Coils.

The smallest medical coil in ordinary use has five millihenrys in its primary, 100 millihenrys in its secondary, and 20 millihenrys mutually between them.

A large induction coil, 19in. long and 8in. in diameter, has 0·145 ohms and 13 millihenrys in its primary, 30,600 ohms and 2,000 henrys (by two concordant methods of measurement) in its secondary, and 163 henrys mutually between them.

The inductance of a mirror galvanometer may vary from a few millihenrys up to 10 or more henrys according to its resistance. Two henrys is a fair average for an astatic mirror galvanometer of 5,000 ohms.

An ordinary electric bell of 2·5 ohms resistance was found to have an inductance of 12 millihenrys.

There is one point in connection with the self and mutual inductance of induction coils and transformers that deserves attention, owing to the confusion that occasionally arises concerning it. It may be, perhaps, best represented by a numerical example. Let a closed Faraday ring of iron 100 centimetres in mean circumference and 20 square centimetres in uniform cross section, be closely wound with a primary coil of 2,500 turns in one layer, followed by a secondary coil of 7,500 turns also in one layer. If now two amperes be maintained steadily through the primary, the magnetic force in the iron will be $4\pi/10$ times the ampere-turns per centimetre of the iron circuit or $4\pi/10 \times 2 \times 2{,}500 \div 100$ or 62·85. The permeability of wrought iron at this force being, say 250, the induction developed per square centimetre will be $250 \times 62 \cdot 85$ or 15,713 lines, and the total induction enclosed by the primary coil, neglecting the space occupied by the wire itself will be $20 \times 15{,}713$ or 314,250 lines which traverse every turn of both windings. The linkages with the primary will be 2,500 $\times$ 314,250, or in round numbers 786,000,000 and referred to one ampere, half this number, or an inductance of 393 million centimetres, that is 393 millihenrys. Similarly, the linkages of these lines with the secondary will be 23,580 millions, and per ampere of primary current 11·79 millions of centimetres mutual inductance or 11·79 henrys. Next suppose the primary current interrupted, and a current steadily established in the secondary sufficient to produce the same magnetic force in the iron, thus avoiding the complication of a changing permeability. As the secondary has three times as many turns, the current effecting this will be two-thirds of one ampere. The total induction through the iron will now be the same as before, and therefore the linkages will be equally numerous. The self-inductance of the secondary will be $2{,}358{,}000{,}000 \div 2/30$, or 35,370,000,000 centimetres ; that is, 35·37 henrys. The mutual inductance will similarly be $7{,}860{,}000{,}000 \div 2/30$, or 11·79 henrys as before. It will be found, on carrying the reckoning to the necessary degree of accuracy, that this mutual induction 11·79 is the square root of the product of the two self-inductances, $0 \cdot 393 \times 35 \cdot 37$.

Examination of the steps in this calculation will show that this proposition must hold for all closed magnetic circuits uniformly magnetised to the same degree when the space occupied by the windings is not taken into account. Under the opposite conditions of open and especially of short iron cores, with large winding spaces, the condition usually fails, and the mutual inductance may be greater or less than the square root of the self-inductances multiplied together.

Another reason in favour of selecting 1,000 million centimetres as the value of the practical unit or henry, is the desirability of having the time-constant of an electro-magnet circuit expressed directly in seconds by its practical units as in the case of electrostatic circuits, rather than revert to a unit of inductance that would yield the time constant in milliseconds or other fractional period of time. The time constant of a simple electro-magnetic circuit, a circuit having inductance and resistance but negligibly small electrostatic capacity, is defined as the ratio of its inductance to its resistance, that is of its henrys to its ohms. It is an important function, and its consideration presents some remarkable analogies between inductance and electrostatic capacity that it is interesting to trace.

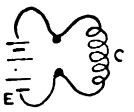

Fig. 2.

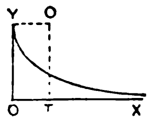

Fig. 3.

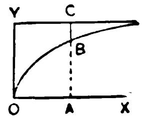

Fig. 4.

Imagine au inductance coil, C, without iron to be supplied with a steady current from an electromotive force, E, of 50 volts. Let the inductance of the coil be three henrys, and its resistance 10 ohms. (Fig. 2.) Ohm's law determines the strength of the current to be five amperes. Now short-circuit the terminals of the coils very suddenly by a wire across its terminals of negligible resistance. The current in the coil C does not stop instantly, but under the name of extra current is maintained in the coil by reason of its inductance. According to theory, the last dregs of the current will never entirely vanish from the coil, although after the first few seconds the remainder is exceedingly small. The very first instant after short-circuiting the current continues at five amperes by its electro-magnetic momentum, but being unsupported its energy is lost thermally in overcoming the coil's resistance, and it immediately falls. In falling, the lines of force linked with the circuit and sustained by the current, are drawn in, cutting the coil as they recede, thus creating a counter E.M.F. tending to prolong the current, and this process of dwindling current with reduction of opposition from the reserve of inductance, descend together. The total quantity of electricity that will flow through the circuit under the conditions specified, may fairly be called the charge or discharge of the coil, and it can be readily proved that this charge is equal to the quantity that would be conveyed by the initial discharging current, acting uniformly during a time equal to the time-constant of the circuit. In this case the discharge commenced at five amperes, and the time-constant is 0·3 second, so that the total discharge will be that due to the flow of this current in 0·3 seconds, that is 1·5 coulombs.

To represent the case graphically, suppose the curve of discharge in time to be plotted as in the figure. Let the axis OX be divided off into seconds, and the axis OY into amperes. (Fig. 3.) The discharge commences at five amperes, subsides rapidly at first, but at last so slowly that an indefinitely long time must elapse before it altogether disappears. The area enclosed between the curve and the axes represents ampere-seconds or coulombs to the amount of the total charge, and the proposition just stated asserts that if the current had continued at five amperes steadily for 0·3 seconds, the area of the dotted rectangle so generated, YDTO, would be equal to the total area enclosed between the curves and the axes prolonged to the ultimate point of union.

Curiously enough, exactly the same law applies to the discharge of a condenser through a circuit of resistance but negligibly small inductance. The time-constant of the circuit in this case, however, being its capacity in farads multiplied by its resistance in ohms.

The curve of discharge is of the same type for inductances or capacities. It is logarithmic, and finds its prototype in the case of the discharge of water in time, from a tank having a faucet at the base, assuming that the rate of escape through the faucet at any moment is directly proportional to the pressure or level of water then remaining in the tank.

The laws which control the outline of this discharge curve are identical for condensers or short-circuited inductances, and are combined in the following enunciation:—

The natural logarithm of the ratio of the $\left\{\frac{\text{full charge}}{\text{initial current}}\right\}$ to the $\left\{\frac{\text{residual charge}}{\text{discharging current}}\right\}$ at any instant is the quotient of the the time during which discharge has been in progress by the time-constant of the circuit.

In this statement two reservations are necessary.

The electrostatic circuit must be free from all appreciable inductance, and the electro-magnetic circuit must contain negligibly small electrostatic capacity. It was first pointed out by Sir William Thomson that the discharge of a condenser through an inductance circuit becomes oscillatory when the inductance exceeds a certain critical value.

When an inductance discharges through a break instead of a closed circuit, the conditions become complicated to a degree that eludes complete practical solution in the present state of knowledge.

At the period of natural discharge equal to the time-constant, an inductance or capacity charge or current will have fallen to 36·8 per cent. of its initial value.

Similar propositions relate to the charging currents and quantities. In the above instance, after the coil has completely discharged, remove the short-circuiting wire. The current will immediately enter the coil, and the curve of its arrival in time is represented in Fig. 4, this curve being only an inversion of the preceding. For this reason it is evident that the area above the curve now represents the charge, and by an extension of meaning, the deficit from full current, such as B C, may be called the charging current, since on discharge and reversal of the diagram, this will be the discharging current at the same lapse of time. In fact, the current A C is doing work in heating the coil, the deficit from ultimate current B C being only active in increasing the electro-magnetic momentum of the circuit, and work is really stored in the coil as though the deficit current did exist. A similar but inverted curve of current in time represents the charge of a condenser. In each case, and under the above restrictions, the following propositions hold:—

The natural logarithm of the ratio of the $\left\{\frac{\text{full charge}}{\text{initial current}}\right\}$ to the $\left\{\frac{\text{deficit from full charge}}{\text{charging current}}\right\}$ at any instant is the quotient of the time during which the charge has been in progress by the time-constant of the circuit.

When the charging interval reaches the time-constant, the charge will have attained 63·2 per cent. of its full value.

Another relation between simple electrostatic or electro-magnetic circuits and their time-constants is in their stores of energy. The energy of the charge in each case is half the energy that would be developed by the initial charging or discharging current against the ohmic resistance of the circuit in the time equal to the time-constant. In the above instance, for example, five amperes being the initial charging or discharging current, and the resistance 10 ohms, the circuit energy of this current per second would be $5 \times 5 \times 10 = 250$ joules, and during half the time-constant the energy thus developed would amount to $0·3 \times 250 \div 2$ or 37·5 joules. This is the electro-magnetic energy stored up in the charge.

These are not the only analogies that exists between inductance and capacity, but there are remarkable points of diversity. The discharge of extra current of a coil is in the same direction as the circuit current, with the condenser it is the reverse. In a great many practical instances, the electro-magnet and the condenser are used to annul each other's influence.

The time-constant of an inductance circuit is generally small, for the reason that a coil of large inductance has generally many turns, and, therefore, high resistance, so that the ultimate ratio of the henrys to the ohms is not large. For example, the time-constant of a Bell telephone, considered in itself or on short circuit, is from the measurement above described, about $0·09 \div 75$ or 0·0012 seconds, and therefore a steady E.M.F. of, say, two volts, impressed directly upon such a telephone would produce in this interval of time 63·2 per cent. of 2/75 amperes, namely, 169 milliamperes. By adding inductance less resistance to the circuit, however, and raising the E.M.F. proportionately, the time-constant would be lessened, and the arrival of current accelerated. Strictly speaking, this reasoning is inaccurate, since the telephone coil surronnds iron, but with the small currents usually employed the iron probably does not greatly influence the arrival curve. In the case of dynamo field-magnets, and large ironclad inductances generally, the divergence of the arrival curve from that of a corresponding simple electro-magnetic circuit is considerable.

There are several methods by which self and mutual inductance can be measured, the selection depending on the magnitude to be determined and its nature. The Ayrton and Perry secohmmeter, or double revolving commutator, is, perhaps, the most generally useful. It may be employed in connection with a standard condenser, a standard inductance, or apparent change of resistance with speed. Being used in the Wheatstone bridge, the currents it can alternate are necessarily limited in strength.

For small inductances,* say less than one-tenth of a millihenry, the method of Prof. Hughes,† or its modification by Lord Rayleigh, is probably best suited, using two coils of mutual inductance and a telephone as the observing instrument.

The inductance coils are usually in the form of two concentric rings, the inner being capable of rotation about the common vertical. The mutual inductance of such a pair of coils is a complex function of the dimensions and the angle between the planes at which the coils may be set. It is usual to calibrate the instrument by separate measurements of the inductance at different angles. A simpler arrangement, however, for mutual inductance is a short solenoid in the bridge circuit superposed coaxially upon a long solenoid in the battery circuit. Adjustment to silence in the telephone for interrupted currents is then made by including in the bridge circuit a greater or less number of turns in the outer solenoid. The mutual inductance is then very nearly proportional to the number of turns so included, and by suitable proportions in construction the accuracy can be carried as far as the telephone for the receiver will permit.

For the measurement of inductance in coils on iron machinery, the ballistic galvanometer is frequently employed, either by the method of discharge for self-inductances, or induced quantity with mutual inductances. Mutual inductances connected by closed iron circuits present no difficulty when great accuracy is not required, since, as already observed, the self-inductances are calculable in these cases when the mutual inductance and the number of turns in the coils are known. It is much more difficult, however, to measure the self-inductance of the field-magnet of a dynamo when the armature is removed, and when currents of the normal exciting strength are used in the measurement. The best attempt has been made, apparently, by observing the discharge effects of gradual small changes of a strong current passing through the coil, in circuit with a specially arranged Wheatstone bridge.‡ If it were of sufficient practical importance, however, to measure such inductances with powerful currents, a recording instrument might be tried, having a very light and swiftly-moving pointer, leaving a trace of its motion on a strip of moving paper like Sir William Thomson's syphon recorder. If such a pointer were arranged to give an amplitude of movement at right angles to the paper strip, in proportion to the current traversing the coil, it would register the curve of discharge when the coil was short-circuited, in the manner described above. On a sufficiently enlarged scale, corrected, perhaps, for residual inertia in the moving parts, this curve would give, not only the total quantity of discharge, but its deviation from the logarithmic line of simple electro-magnetic discharge, would give the means of determining the characteristic of magnetisation in the iron.

Of far lesser importance than the selection of the practical inductance unit, but still well worthy of separate consideration, is the selection of appropriate symbols to represent the unit briefly. It might, perhaps, be advantageous to represent the henry by a capital H, and the millihenry by the plain letter h. This notation would enable such an inductance as 50 henrys to be written as 50 H, and 50 millihenry as 50 h. The microhenry occurs so seldom that it would probably not need a symbol.

All measurements of precision should employ true ohms and not legal ohms in the computations. The best existing value of the true ohm is 1·0028 legal ohms.‖

The correction it practically so small that it can best be carried out by altering the nominal standard temperature of the resistance coils adopted. These temperatures should be increased by 9·4°C. for platinum-silver, 6·5°C. for German-silver, and 13·5°C. for platinoid. Thus, a resistance box with platinum coils standardised for legal ohms (of 106·0 cms.) at 15°C. would give true ohms of 106·3 cms. at 24·4°C. as the best approximation, and this would be the standard temperature of the box for use in precise measurements of inductance.

## LUBRICATING OIL.*

BY A. C. J. CHARLIER.

During the last few years great improvements have been introduced in the manufacture of lubricating oils. Looking back some twenty years, we find that the users of lubricants could not be persuaded to use anything but castor or sperm oils ; but gradually, from the researches and investigations made by specialists in this class of oils, compounds and carefully prepared mineral oils have been introduced which far surpass the old lubricants both in price and quality. In order to be able to determine the utility of the great number of these lubricants now in the market, and in order to determine the proper lubricant to choose for the different classes of work, it is more than ever necessary for users to become acquainted with easy methods of analysis and examination, as well as to know the nature and general qualities of the oils of which the compounds generally consist.

Before dealing with the oils used for lubrication, it is necessary to consider what constitutes an efficient lubricator. A good lubricating oil must have sufficient body to keep the surfaces between which it flows from coming into contact, hence the reason why high gravity oils are now so much used on all classes of machinery; but at the same time everything depends on the class of work on which the oil is to be employed. If for light machinery, a very heavy oil would have a tendency to clog the bearings, thus impeding the speed ; therefore for all ordinary machinery an oil ranging in gravity from ·850 to ·890 should be employed ; whilst for heavy machinery, oils ranging from ·900 and·980 should be chosen.

Another important feature is to obtain oils having the greatest amount of fluidity consistent with body. Many oils are selected because they are apparently of high gravity, but such in reality is not always the case. The commonest paraffin burning oils can now be given an artificial gravity resembling castor oil, and yet immediately they become heated, even to a moderate temperature, they run off the bearings like water. Many of the Russian mineral oils now on the market have a gravity of about ·920, are very highly refined, and of a splendid colour, and yet when heat is applied they instantly lose their gravity, become limpid, and are quite useless for the purpose for which they are required. But still it must be mentioned here *en passant* that these Russian oils are very useful in making up compounds with oils not affected by temperature, as they then supply body to an oil which, although an excellent lubricant, could not be used for heavy machinery on account of its low gravity.

Another point to be considered is to find an oil with a maximum capacity for receiving and distributing heat, together with a freedom from tendency to gum or oxidise, hence none of the drying oils should be used for lubricating purposes, and under this head users of lubricants must be warned against a process which has lately been discovered of adulterating lubricating oils with soap, by which is produced a very fine sparkling oil of gravity higher than castor, but at the same time utterly useless for lubrication. Users of lubricating oils often lay far too much stress on the colour of the oil, but with many methods now known of giving any oils, good or indifferent, any colour, either ruby, golden or black, by the addition of the smallest percentage of the many aniline colours soluble in oils, the colour should no longer be taken as a test of quality, all that is required being that the oil should be bright and free from insoluble matter. It is essential that a lubricating oil should be neutral—that is, it should neither be acid nor alkaline. In the refining of many kinds of oil, mineral acids and alkaline earths are used, and, especially in the cheaper oils sufficient care is seldom exercised in washing them free from all traces of acid ; and then, again, it is well known that manufacturers often leave a large portion of alkali in the oils, as this greatly helps to make up their gravity.

Having now dwelt on what are the requirements of a good lubricant, the next step will be to describe several ready tests by which the utility of the oils can be quickly determined ; not tests and analyses which can only be worked by competent chemists, but ready methods which can be employed by any ordinary user of machinery. With regard to the gravity, this is an essential step, and in order to find this we have gravity bottles, Sprengel's tubes, &c., all of which necessitate the use of a balance. The simplest method is therefore to use an ordinary hydrometer. The oil is placed in a cylindrical glass vessel, and the hydrometer floating in the oil marks immediately the gravity, taking water as 1,000. This method is very useful, because the gravity of the oil can be determined at any temperature ; whilst by the more complicated methods it is very difficult to determine the gravity at any other temperature than that of the ordinary atmosphere ; but with the hydrometer the glass vessel can be heated in a water bath, and the gravity taken by placing the hydrometer in the oil at any moment. By this means it can be seen if the sample retains its original gravity when heated.

* From the *Engineer*.

The "flashing point" of an oil is understood to mean the temperature at which the escaping vapour will momentarily ignite. The standard animal and vegetable lubricating oils, and all mineral oils of good body and high gravity, decompose or vaporise only at temperatures exceeding that of steam in ordinary engines, but nevertheless many of the lubricating oils now in the market are so worthless that it is very essential to know a ready means of ascertaining their flashing point. Many very good forms of testers, such as Abel's, Bernstein's, or Bailey's, are used, and they are more or less on the same plan, namely, consisting of a metal receptacle for containing the oil surrounded by a water-bath with a lamp for heating the bath. The vessel containing the oil is closed, with the exception of a small aperture through which the vapour ascends ; a small gas jet is continually played over this aperture, and instantly the vapour flames the temperature is noted, this constituting the flashing point of the oil. But all these testers require very careful manipulation, and the writer, therefore, suggests a simple apparatus, which can be worked very easily, and at the same time gives very accurate results. A small glass beaker is fitted into a larger one by means of a cork or india-rubber band ; the former is to contain the oil, the latter serves as a water bath. The smaller beaker is closed at the top by means of a cork, through which is inserted a thermometer dipping well into the oil, and a small piece of glass tubing tapering to a point, through which the vapour ascends. The oil should be on an exact level with the water in the outer vessel, so that the same pressure exists in both vessels ; and when an oil to be tested is supposed to have a flashing point above that of boiling water, an oil bath should be used in place of water. Everything being ready, the apparatus is stood on a sand bath, under which is placed a spirit lamp, and gradually heated. A lighted taper is applied continually to the aperture through which the vapour from the oil is ascending, and immediately a small blue flame appears the temperature is noted, and the flashing point of the oil under examination thus determined. Any oil having a flashing point below 300deg. Fah. should be at once discarded as useless.

Another very important test is the viscosity or fluidity of an oil, and here again we have some very elaborate apparatus recommended to us, but an engineer is in want of ready and quick tests, not such as would take him perhaps a day to work out, but one that can be worked in a few minutes, and at the same time give him accurate results. A very simple and general test of fluidity is to dip blotting paper in the oil and hold it up to drain ; symmetrical drops indicate good fluidity, a spreading tendency viscosity. Again, an ordinary glass tube having a diameter of half an inch, tapering to a point at one end, and marked into divisions of 1in., will answer all ordinary purposes for testing the viscosity of an oil. The oil to be tested is placed in this tube up to a given mark, and is then allowed to run out at the tapered end of the tube, and the time taken is noted. This is compared with the time taken by standard oils previously ascertained in the same tube, and thus the viscosity of the oil can be determined. Sometimes it is necessary to take the viscosity at different temperatures, and in this case the glass tube can be fitted into an outer jacket containing water heated up to the required temperature. For all light machinery running at high speed, low gravity oils having a low fluidity should be looked for, whilst for heavy machinery of all kinds high gravity oils, with a moderate fluidity, should be employed.

An oil evaporating more than 5 per cent. in twelve hours, at a temperature of 140deg. Fah., is useless, as the evaporation creates a viscous residue, or leaves the bearings dry. To test for this, a weighed quantity of the oil should be placed in a porcelain dish and heated for the requisite time, then cooled and weighed and subtracted from the original quantity ; the difference in weights constitutes the loss by evaporation.

The best lubricating oil is that which has the greatest adhesion to metallic surfaces, and the least cohesion in its own particles, and bearing this in mind, there is no doubt but that mineral oils come first, sperm oil second, neatsfoot oil third, and lard oil fourth, hence the finest mineral oils are best for light bearings and high velocities, and to give body to mineral oils fine sperm oil is used, or when greater tenacity is required, lard and neatsfoot oils may replace sperm oil, and for the heaviest machinery mineral oils alone cannot be recommended, on account of want of body and higher degree of inflammability.

At the present time, it is not so much a matter of quality which troubles the engineer, but it is the question of cost. Lubricants answering in every way what is required of them can be obtained, but their cost is far too high for the ordinary consumer, and it therefore necessitates producers to search for compounds which will give to cheap oils the same properties as sperm, lard, &c., and be able to sell them at about half the price. Mineral oils are the cheapest lubricants known, and yet they are often discarded for one reason, because they do not possess the same body as many of the vegetable and animal oils, and hence require a larger quantity to be used to do the same work ; but, if double the quantity of mineral oil is required to do the work done by other oils, the price of the former is only one-quarter that of the latter ; hence the mineral oils are still by far the most profitable to be used.

Digitized by Google

Oleate or stearate of alumina is now greatly used for giving a body to light gravity mineral oils. It is a very cheap compound, and can be added at a very small cost. The production of this "metal soap," as it is called, is well worthy of consideration, and can be well classed as a very successful issue to a lot of research work recently done by several chemists in endeavouring to produce cheap lubricants. The high-class animal and vegetable oils in such high favour amongst engineers for their lubricating powers consist principally of olein and stearin, and these two substances, which give to these oils their high lubricating powers, can now be introduced into cheap mineral oils, thereby converting them into the finest lubricants at a cost far below that paid for castor, sperm, and such like oils. The oleic and stearic acid is obtained in the usual way from any of the oils rich in olein and stearin, and is then precipitated with alum in the presence of caustic soda, thus forming oleate and stearate of alumina. A very small percentage of this metal soap dissolved with warming in light gravity mineral oils will increase their gravity some 50 or 60deg., will greatly improve their lubricating properties, and after filtering through fine copper gauze, will give them a brilliancy not surpassed by any of the finest animal oils in the market, and at the same time not increase their cost of production more than 20s. per ton. Some manufacturers use now a process of thickening their oils with ordinary soft soap, but this adulteration can be easily detected by adding glacial acetic acid and warming, when the soap will at once separate out. The writer recently examined a very fine-looking sample of lubricating oil, resembling in appearance castor oil, and found on estimation that as much as 60 per cent. of soap had been introduced into the oil. Any oil found to contain such soap should be at once rejected. Lardine and blown rape oil are now also largely used for giving body to lubricating oils. The former consists principally of cotton oil, which has been heated in the presence of a strong blast of air, somewhat similar to the process employed for thickening linseed oil, whilst the latter consists principally of colza oil treated in a similar manner. The presence of these "thickeners," as they are termed in the trade, cannot be said to visibly deteriorate the lubricating powers of the oil with which they are mixed; but they certainly do not improve it, and unfortunately they quickly become dull and cloudy, and in order to prevent this rosin oil must be used in conjunction with them. A small percentage of, say, 1 per cent. of rosin oil does not deteriorate the lubricating properties of an oil; but one containing above this percentage cannot be recommended for lubricating purposes. The presence of rosin oil can be detected in mineral oils by treating a small portion of the sample with an alcoholic solution of caustic soda, heating on a water-bath and evaporating nearly to dryness, then add a large quantity of distilled water and boil for some time, when a milky liquid will be formed; now add more water and warm, and notice the colour of the oil that separates out, if clear, then mineral oil is only present; a brown colour denoting the presence of rosin oil. As a confirmatory test, draw off the aqueous liquid from beneath and make it acid with sulphuric acid, if no precipitate, the oil was all mineral, as a precipitate collecting on warming in brown viscous drops confirms the presence of rosin oil. But now, if instead of a milky liquid a semi-frosty mass is obtained after having added the distilled water to the evaporated solution, a fatty oil is evidently also present with the mineral and rosin oil, add more water, when the mineral oil will float to the top if present. Now draw off the aqueous liquid, and shake it up with amylic alcohol. If the alcohol separates in a brown layer, rosin oil is present. Again draw off the aqueous liquid, acidulate with hydrochloric acid and warm, when the separation of oleic acid, with its characteristic odour of fat, will show the presence of a fatty oil, either lard, neatsfoot, or cotton oil.

For the lubrication of bearings of the largest size on which, either from the weight of the shaft or fly-wheel, or from the drag of belts or ropes or from the formation of the bearing, very great pressure per square inch has to be resisted, castor oil up to the present appears to have no equal; and, in order to keep such bearings cool, it is very essential that this oil should not be adulterated. The adulterants to be looked for in castor are principally lard oil and colza, and they can be at once recognised by its density. The specific gravity of castor oil is ·960; lard oil, ·916; rape oil, ·912; therefore if the gravity is below ·955, this alone proves the presence of one of these oils. Again, another very characteristic test of castor oil is by the addition of zinc chloride. If pure it becomes yellow; if lard oil be present it becomes milky, and if colza be present a green coloration is obtained. Again, sperm oil is still very largely used by the leading cotton spinners, and the reason for this is that it leaves no stain, and does not thicken by age or friction. Here again, on account of the high price of this oil it is often adulterated, and generally with seal oil, cotton, and mineral oils. These adulterants can also be easily detected with zinc chloride; if pure sperm oil a milky solution is obtained, and when adulterated with any of the above-mentioned oils a brown coloration is obtained.

This article would not be complete without noticing the qualities of tallow as a lubricant, and there is no doubt but that, while in every case hydrocarbon oils are safer, and in the majority of cases are better and cheaper lubricants than tallow, even of the best quality, there are a number of cases in which engineers, although fully alive to the trouble and danger which are inseparably connected with the use of tallow, are constrained to use it, having failed to find any sufficient substitute. The great fault with tallow is that it corrodes metal, and often leaves a kind of deposit; and, again, it almost always contains free acids, as much as 25 per cent. of free fatty acid having been found in a sample of town tallow. Large proportions of free acid are apt to be due to the tallow being adulterated with wool grease acids, or stearic acids from cotton-seed oil. Tallow, again, frequently contains more or less water, infusible matters, and mineral impurities, and has been often purposely adulterated with starch, China clay, whiting, &c. For the detection of these mineral impurities, a small sample of the tallow should be dissolved in petroleum spirit, filtered, the residue washed with a little ether, and dried at a moderate temperature. Boil the residue in water, and add iodine, a blue coloration is obtained, proving the presence of starch; again, any effervescence of the residue on addition of hydrochloric acid proves the presence of whiting.

## THE "MONARCH" MAGNETIC SEPARATOR.*

BY C. M. BALL.

The magnetic concentration of iron-ores has been so often and so widely studied and discussed among the members of the Institute that any remarks concerning its general importance, from an economic standpoint, would be superfluous; but it is thought that a description of the Ball and Norton ore-separator, designed for cobbing and separating magnetic iron-ores, indicating its essential differences from other machines and the advantages claimed for it, together with some account of recent results obtained in its application to the concentration of such ores, will prove of interest.

The accompanying illustration represents a longitudinal vertical section of the perfected Monarch ore-separator, adapted for separating fine ore.

The apparatus consists of a partially-closed chest, having an opening at *f*, from the feed hopper *h*, through which the ore is delivered to the machine from a storage-bin provided with means for regulating the flow of ore, so that, when the machine is in operation, the hopper is kept always full. Other openings are provided for the discharge, at *t*, of tailings; at *m*, of middlings; and at *c*, of concentrates; also at *e*, for allowing free ingress of air to the chest at that point, and at *s*, where a powerful exhaust-fan is connected. The openings at *t* and *m* are kept sealed against ingress of air at those points by means of the hinged and weighted valves, *v*, *v*, which discharge the products from the hoppers *p* and *k* continuously, and in the same proportion as received from above, when a sufficient weight has accumulated upon the inside to cause the contents of the hoppers to leak by the valves. The machine is also provided, as shown, with two drums, Nos. 1 and 2, turning upon the shafts *i* and *j*. These shafts, together with the magnets *a* and *b*, which they also serve to support, stand still while the drums may be rapidly revolved around the magnets and out of contact therewith. The magnet is so constructed as to present a series of poles of alternately opposite polarity near the inner surface of the drum. Any magnetisable matter brought near the outer surface of the drum, within the arc covered by the magnet, will be powerfully attracted and drawn into firm contact with the outer surface of the drum.

These drums are composed of a non-metallic material, such as wood, paper, &c., and they turn in the direction indicated by the arrows. Just below the feed-hopper an apron of neutral metal, No. 3, is arranged, curving downward and forward in the direction of the rotation of the drum, its lower portion describing a short arc concentric to the surface of the drum. This serves as a shoot to direct the stream of ore falling from the feed-hopper within the influence of the first two or three poles of the magnet. A similar but somewhat shorter apron, No. 4, is arranged in like relation to the second drum, and magnet *b*.

Attention is called to the provisions for applying and directing the air-current, which fulfils an important function in the process of separating ore as developed in this apparatus. The air may enter freely at the openings *c* and *e*, and is drawn through and out of the chest by the action of a powerful exhaust-fan connected at *s*. The air which passes through the chest follows the course indicated by the arrows in the space below the drums.

When the machine is put in operation, and the magnets are excited, the drums are revolved in the direction before indicated, and the air-current is established through the machine in a direction opposite to that of the rotation of the drums, ore being supplied through the feed-hopper, which is kept always full. The ore

* Paper read before the American Institute of Mining Engineers, New York, September 30, 1890.

Digitized by Google

passes down the shoot under the first drum, and, as soon as it comes within the influence of the magnet, the magnetisable portions are drawn into contact with the drum, and, through friction upon its surface, take on the forward movement of the drum. At this stage, a curious and important result takes place. The particles simultaneously influenced by the same pole, form tufts standing out from the pole. As they are drawn along, however, by friction against the moving drum, when they get to a point midway between two poles they lie down flat against the surface of the drum, and, as they are drawn still further along, they again stand on end—but this time the other end out. So, in passing through the magnetic field, they are tumbled end over end as many times as there are poles in the field. The result is, that every time they are reversed in position opportunity is afforded for any non-magnetic particles of gangue, which may have been entangled with the ore, to fall away from the tufts of magnetite; and this result is still further facilitated by the centrifugal tendency and by the counter current of air. When the ore reaches the limit of the arc covered by the magnetic field it is no longer attracted, and takes on a tangential movement, which carries it away from the drum. It has now, however, passed the edge of the second apron, and, on leaving the first drum, comes within the influence of the magnet of the second drum, where similar operations are repeated, a portion being finally discharged as concentrate at c.

The separation of the middlings from the mass delivered to the second drum may be effected in two ways: If the drums have the same speed of rotation, a weaker magnetism in the second magnet will allow these less magnetic particles to drop away; or, if the magnets have approximately the same force in the two drums, a higher speed of rotation of the second drum will throw these particles off by reason of the centrifugal force overpowering the centripetal magnetic attraction, the magnet having the smallest influence upon the leaner portions of the mass.

Modifications of this apparatus have been designed, which adapt it for use in conjunction with a stream of water mingled with the ore, so constituting a wet process.

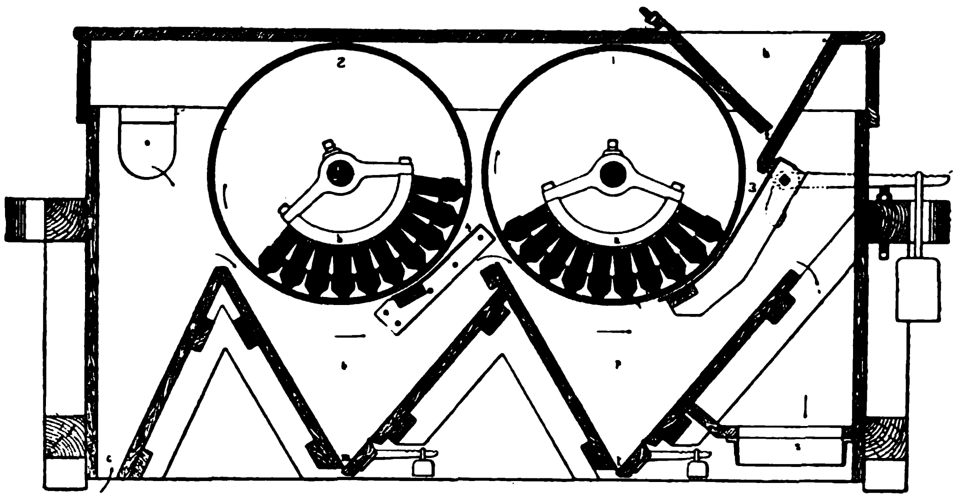
The importance and special efficiency of the means provided for suppressing the movement and discharge, along with the ore, of the finer particles of gangue, and of the means for differentiating the product into several portions graded according to the percentage of iron in each portion, and its magnetic susceptibility should not be overlooked. It is upon the application of these means that the ability depends to perform the critical operation of converting non-Bessemer into Bessemer ores by the elimination of phosphorus, sulphur, and titanium-bearing compounds.

In the concentration of ores by the dry process the treatment of the dust developed in the rapid movement of large quantities of ore is generally difficult. When the ore reaches this machine, the finer portions of the material are as readily and perfectly dealt with and separated as the coarser, the concentrates, however, finely pulverised, being delivered from the machine in an absolutely clean condition, and free from non-magnetic dust, and the dust carried away by the air current being also as wholly free from any magnetic material.

The positive character of the functions above enumerated renders it possible to make an effective separation under the conditions of a very heavy supply of ore to the machine. The easy working capacity of a machine having drums of 24 inches diameter, and 24 inches working-face is from 15 to 20 tons per hour of ore granulated to pass 16 to 20-mesh screens. The power required is from 1 to 1½ horse-power in electricity for each drum, and ½ to ¾ horse-power to drive the machine.

These machines have been applied to the treatment of a considerable number of ores with good results. The most remarkable of these was the conversion of Port Henry Old Bed ore into a Bessemer ore carrying Fe. 71·10, P. 0·037. This concentration was made from the crude ore, carrying Fe. 58·7. $P_2O$ 2·25, the Bessemer concentrate representing about 65 per cent. of the original mass. An earlier type of this machine was in use during nearly the whole of the year 1889, at Benson Mines, St. Lawrence County, N.Y., concentrating the lean magnetite mined there, which in the crude ore carries about 40 per cent. Fe., and is above the Bessemer limit in both phosphorus and sulphur. The concentrated product found a market at Pittsburg, Pa. The new works at the Benson Mine are provided with crushing machinery having sufficient capacity to crush daily 800 to 1,000 tons of ore, sized to 16-mesh, and finer, and the separation of this quantity of ore is to be effected at the outset with three separators, having a working face on the drums of 24 inches.

In the minds of some persons who have been studying the general subject of ore-concentration, and employing the apparatus hitherto available, inability to convert some of the well-known ores high in phosphorus and sulphur, such as Port Henry Old Bed, Little River, Croton, etc., from non-Bessemer into Bessemer ores, has led to the inference that some as yet undiscovered refinement of preparation was essential to their successful treatment. The entirely successful and economical management of these ores with this machine has proved that the essential matter in the problem was to provide a separator that would separate ore that had been properly prepared.



Section of the Ball Magnetic Ore Separator.

## THE INTERNATIONAL ELECTRICAL EXHIBITION AT FRANKFORT-ON-MAIN.

The exhibits at this year's Electrical Exhibition at Frankfort will be divided into 11 sections. In the section devoted to railway appliances the Prussian and Bavarian State Railway Departments will both send exhibits of signalling and lighting apparatus. In this section will also be found four electric railways, illustrating the overhead and underground conductor systems, and also accumulator working. In the telephone and telegraph sections, the German Government will show a historical collection of apparatus. The Bavarian, and probably the English Governments, as well as a large number of private firms, will send examples of the latest forms of apparatus. Messrs. Siemens and Halske's exchange instrument, which works a number of type-writers from a central station, will be shown, and also Messrs. Mix and Genest's telephone automaton. Special rooms will be provided containing telephones connected with concert-halls in Frankfort, Wiesbaden, and Münich. The electro-chemical section will contain exhibits from 14 firms. Amongst other processes one for obtaining pure copper from its ores will be shown. The Aluminium Company of Neuhausen will have a good show of specimens of aluminium and its alloys. Amongst the exhibits in the medical section will be the arrangement adopted by Hertz in his researches on the nature of electricity, and numerous specimens of laboratory apparatus, sent both by scientific institutions and by private firms. Messrs. Hartmann and Braun and Messrs. Siemens and Halske in particular are sending interesting collections.

In the boiler-house and machine-room 60 exhibitors are represented. Boilers on 20 different systems, with a total heating surface of 2,400 square metres, will be at work, while 56 steam and other motors from ½ to 600 horse-power, the total being 3,900 horse-

Digitized by Google

power, will be put down. These will include, besides compound, tandem and triple expansion engines, several locomotive engines up to 100 horse-power, as well as many small engines, worked with steam, petroleum, coal gas and Dowson gas.

Twenty-two firms are sending dynamos. Some 600 horse-power dynamos (the largest hitherto built in Germany) are to be included. A large number of alternators will be shown and methods of transmitting power by the alternating current will be illustrated. About 500 horse-power are to be transmitted to the exhibition by electricity. Of this total 100 horse-power are to be brought from the Palmengarten, 100 horse-power from Offenbach, and 300 horse-power from Lauffen-on-Neckar, 100 miles away. At a conference recently held at Münich, between the Allgemeine Elektricitäts Gesellschaft, the Maschinenfabrik Oerlikon, and the Lauffen Cement Works satisfactory arrangements were concluded with regard to the division of the cost of this transmission. The carrying out of the scheme only depends now upon the action of the German Postal authorities, who have been asked by the joint committee of the three firms to lend the necessary telegraph posts and fittings. There will also be six batteries of accumulators capable of furnishing 400 horse-power.

In the distribution room a large collection of apparatus will be in use. Messrs. Siemens Brothers are laying down a cable to carry a current at a pressure of 20,000 volts. In this room the current will be supplied to the lighting and the power mains. Electric motors will drive 5 pumps, taking in all 250 horse-power, to supply water from the river Main to the Exhibition. Power from the same source will also be used to work a fire engine, a glow lamp factory, a mill, and mining machinery. In the installation apparatus room 75 firms are represented.

A committee composed of representatives from the various States will carry out tests on the apparatus exhibited, and the results will be subsequently published.

## SOME OBSERVATIONS ON THE EXISTENCE OF RESIDUAL MAGNETISM IN TELEPHONES.*

BY S. KALISCHER.

In December last the author observed that a Siemens telephone, the two ends of the winding of which were insulated from each other, gave out a sound if an induction apparatus in proximity to it was at work. The axis of the telephone was horizontal and at right angles to that of the coils of the apparatus. If the telephone was turned on its axis, or the coils on it short-circuited by a short wire, the sound diminished, and even became inaudible. If the axis of the telephone was parallel to the axis of the coils, no difference was noticeable in the intensity of the sound, whether the telephone circuit was open or closed.

In order to study this interesting phenomenon, some thick wire was coiled in a single layer round a bundle of iron wires as a core. Two Tudor accumulators supplied the current, and a Wagner key placed outside the laboratory served to interrupt the current. Results similar in kind to those above recorded, though varying in intensity, were again observed. When the axis of the telephone was placed at right angles to that of the inducing coil, minima appeared when the limbs of the magnet were one above the other; maxima when they were side by side. When the telephone circuit was open, the sound was always louder than when it was closed.

The telephone circuit being open, the sounds could not be due to any current induced in its coils, so that the phenomenon is not electrical, but magnetic in its nature. This can also be proved directly by the employment of a telephone without coils, when a sound of the same character as before may be heard.

The reason why a telephone with its circuit closed gives out a less loud sound than one in which it is open is not clear, and the difference does not appear in telephones of some forms. Several considerations, however, concur to prove that the iron membrane is the cause of the sound. To test this the magnet was removed from the telephone, leaving the membrane still free to work. The same sound was still observed, and was even increased in intensity. If the membrane was turned about a vertical diameter the loudness of the sound was changed, and in general it was easy to distinguish two positions of minima, the angle between them being 180 deg., and two of maxima, 90 deg. from each position of minimum. Maxima occurred when that diameter of the membrane which was parallel to the line joining the poles of the magnet was parallel to the axis of the induction coils, and minima when these two lines were at right angles to one another. It may, therefore, be concluded that the phenomenon is due to residual magnetism in the membrane. In order to prove this, membranes of tinned sheet iron were used which had never been in contact with a magnet. These gave no sound, but as soon as they had been magnetised the effect described could be observed. Apparently, this gives a very sensitive method of detecting traces of residual magnetism in such plates.

It seems that the above phenomenon is quite independent of the direction in which the current flows through the inducing coil.

* Wiedemann's *Annalen*. Vol. XLI., Part 11.

## BOROUGH OF NOTTINGHAM ELECTRIC LIGHTING.

**The following are the particulars issued to contractors who are tendering for the public lighting of the borough of Nottingham:—**

The Corporation of Nottingham have appointed an Electric Lighting Committee to carry out a Provisional Order, granted to the Corporation on August 4, 1890, for supplying the borough of Nottingham with electricity.

By Clause 59 of the Order, the Corporation are empowered to transfer their powers, duties, and liabilities to any company or person with the approval of the Board of Trade, and the Committee are desirous of adopting this method of working the Order.

By Clause 17 of the Order, the undertakers are compelled, within two years from August 4, 1890, to lay down proper mains for the purposes of general supply throughout the streets shown in the plan and thereon marked with a red line. Subsequently the undertakers have to supply such other parts of the borough (edged with pink colour on the same plan) as they may be required to do in pursuance of the usual requisitions of owners or occupiers, and on proper guarantees being given by them. The undertakers may appeal to the Board of Trade if they consider that any such requisitions are unreasonable.

Companies or persons prepared to contract and find the necessary capital for working the Order and relieving the Corporation of all responsibilities thereunder are requested to submit tenders to the Committee stating fully:—

(1) The terms and conditions on which they would work the Order under such transfer, and particularly—

(*a*) What advantages would be offered to the Corporation for the transfer?

In case a share of the profits be proposed, what percentage of profits above a certain limit would be given to the Corporation, and what would be such limit?

(*b*) What concessions would be made in favour of the Corporation in mitigation of the provisions of Section 2 of the Electric Lighting Act, 1888, in the event of the Corporation desiring to re-purchase the undertaking?

(*c*) For what period would the transfer be taken?

(*d*) Would the extra expenses thrown upon the Corporation staff, or otherwise, be borne by the transferees?

The transferees must pay the cost of the Electric Inspector to be appointed under the Order.

Would they indemnify the Corporation from all consequences whilst working the Order?

(2) The security to be given for working the Order properly, or in the case of a company, particulars of capital paid up, and uncalled and the amount available and proposed to be spent for the carrying out of the Order.

(3) The system of supply to be adopted (which has to be approved by the Board of Trade).

(4) The provisions to be made for ensuring the safety of the public from contact with wires, &c. No overhead wires will be allowed.

(5) Nature of the works which would be executed. The Corporation are prepared to negotiate for the sale or lease of a centrally situated property which they think would be suitable for a central station. If the company would provide their own site its proposed position and area must be stated.

(6) The price proposed to be charged for energy per Board of Trade unit per quarter; the maximum charge allowed by the Order is for any amount up to 20 units 13s. 4d., and for each unit over 20 units 8d.

(7) References to places where previous work of the contractors in electrical installation on the system proposed to be adopted in Nottingham can be inspected by the Committee.

(8) The Corporation will reserve all powers given by the Order to the undertakers of breaking up or interfering with any streets, and will execute such necessary works in connection therewith as may be properly required by the transferees, and charge the costs thereof to the transferees, who must in the first instance make a sufficient deposit to secure such costs.

(9) The transfer will be made subject to the provisions of Clause 59 of the Order.

Copies of the Provisional Order may be obtained from Messrs. Sharpe, Parker, and Co., 12, New-court, Carey-street, London.

Sealed tenders must be sent to the undersigned, marked "Electric Lighting Tender," on or before February 1, 1891. The Committee are not bound to accept the lowest or any tender.

## AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December* 26, 1890.

**The Baxter Traction Motor.**—A new electric railway company is about to enter the field with a complete system of its own. It is the Baxter Company of Baltimore, which is one of the old established stationary motor companies. Until the present time it has done nothing in the way of railway work, but it is just now getting ready to exploit a railway motor vigorously. To-morrow the Company holds a test at its factory, at which the new machinery will be exhibited to a large number of prominent electricians. It is understood that the special feature of the Baxter system is a slow speed motor.

**Edison Mining Plant.**—The Edison Company has been doing no small amount of business among the Western mines within the past few months. Mining operators are rapidly coming to realise the advantages of electric lighting and power for their particular branch of engineering, and it is believed that a wide field has been opened for applied electricity. Mine equipments include tramways, electric hoists, electric pumps, electric drills, general lighting, and transmission of power. The Company is making especial efforts to devise a thoroughly practical and successful electric drill, and claims that such a one will be put on the market at an early date. It is for long-distance transmission of power, as in deep and extensive mines, where it is difficult to have steam-power within a reasonable distance of the point where drills must be used, that electricity offers peculiar advantages, both from its convenience and from its economy, and therefore the advent of a thoroughly practical electric drill is much to be desired.

**The New York Electric Club.**—An interesting lecture was recently delivered at the New York Electric Club by Prof. F. B. Crocker, on the subject of "Electrical Units of the Present and Future." It was a clear and popular account of the origin, derivation, and meaning of the principal electrical units in use and to be desired, and has attracted a great deal of attention from electricians in this city. A large audience was present, and the lecture was most enthusiastically greeted. The Electric Club is doing excellent work in bringing a large body of active electricians into daily contact with each other, and establishing pleasant and harmonious relations between them. At its rooms are given, during the winter, a considerable number of lectures by well-known scientific men; besides these, there are less technical gatherings, receptions, dinners, and the like.

**The American Bell Telephone Company.**—Rumours have been started that the Bell Telephone Company on the expiration of its fundamental patents intends to push the telegraph companies in very vigorous style. To this end it is rapidly extending its long-distance lines, and it is apparent to every one that, in spite of the expiration of the patents, the Company will continue its extraordinary prosperity. It is even hinted that at some future day, when its network of lines become more extensive, it may also assume the functions of a telegraph Company. A long-distance telephone wire equipped with Wheatstone transmitters would be a considerable factor in the telegraphic intercourse between two large cities, and whether the Bell Company intends to do such work or not it will be in a position to undertake it if it is desirable.

## TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS WANTED.—The Barnsley Town Council invite tenders for the erection of buildings for a general electric light station in Midland-street and Queen's-road. Particulars are to be obtained after the 9th inst., on personal application, to Mr. J. H. Taylor, the architect, St. Mary's-place, Barnsley, to whom tenders are to be delivered by 3 p.m. on the 16th inst.

VACANT APPOINTMENT.—The India Office requires an assistant engineer for the Ishapore Gunpowder Factory. The selected candidate must have an efficient knowledge of electrical engineering, &c. Some details will be found in our advertisement columns, and full particulars will be given to applicants at the Offices of the Director-General of Stores, India Office, Whitehall, S.W.

SALE BY AUCTION.—Wheatley Kirk, Price, and Goulty announce the sale by auction, on Friday, January 23rd (commencing at 10 for 11 o'clock prompt), at Atlantic Works, City-road, Manchester, of a large quantity of valuable and nearly new high-class engineering tools and machinery by eminent makers. The whole may be viewed on Wednesday and Thursday, January 21st and 22nd, and on the morning of sale. Catalogues can be had at the works, and from the auctioneers' offices in Manchester and London. Further particulars are given in our advertisement columns, and all information will be supplied by the auctioneers.

ELECTRICAL ENGINEERING CORPORATION (LIMITED).—An announcement appears in our advertisement pages of a destructive fire having taken place at the Corporation's Works at West Drayton. It will be seen, however, that the fire will not interfere with the progress of business, the Corporation being able to provide for all contingencies from its own resources.

TRANSFER OF BUSINESS.—The well-known electrical instrument business carried on for so many years by Mr. Richard Theiler, at 86, Canonbury-road, N., under the style of Theiler and Sons, has recently been transferred to Mr. Elphinstone, late assistant to Mr. S. Z. de Ferranti, and the business will be carried on in future by him under its old style and title. We regret to say that the cause of Mr. Theiler's retirement is failing health. It is Mr. Elphinstone's intention to continue to manufacture goods of the best quality, and generally to conduct the business on the lines which have been so successful under Mr. Theiler's proprietorship.

THE FOWLER-WARING CABLES COMPANY.—This Company have removed their general offices from 85, Queen-street, London, E.C., to No. 4, Victoria Mansions, Victoria-street, Westminster, S.W.

PERSONAL.—Mr. W. A. Perry, late manager for Messrs. H. H. Vivian and Co. (Limited), Birmingham, has been appointed the manager of the Phosphor Bronze Company's rolling and wire drawing mills at Aston-road and Bagot-street, Birmingham.

NEW TELEPHONE COMPANY (IN LIQUIDATION).—Notice is given by Mr. W. S. Ogle, the liquidator, whose address is 90, Cannon-street, E.C., that a dividend of two shillings in the pound has been declared in this liquidation, and the same will be paid at the above address any day between 10 a.m. and 2 p.m.

STANDARD ELECTRIC LIGHT AND POWER COMPANY (LIMITED) (IN LIQUIDATION).—A meeting of the shareholders is to be held at Mr. H. Brown's, 13, Victoria-street, London, S.W., on February 12th, at 2 p.m., to receive an account of this liquidation.

THE ELECTRICAL ACCESSORIES COMPANY.—This Company have sent us their illustrated price list, in which their sunk switches appear to be a very useful speciality. The illustration represents

one of these, or rather all that is to be seen of the switch when fixed. It is a common complaint that switches are a serious disfigurement to a well decorated house, and the ornamentation often applied to china switch covers in no wise improves them. The switch itself is sunk in a box suitably constructed to prevent the penetration of moisture, and if it be found that this desirable end is attained in practice, this form of switch should meet with great success.

THE GENERAL ELECTRIC POWER AND TRACTION COMPANY.—About the middle of this year the business of Messrs. M. Immisch and Co. was amalgamated with that of the Electric Traction Company, and the two firms now trade under the title of the General Electric Power and Traction Company (Limited). Work in the Company's mining department has been exceptionally brisk, and installations have been erected in England, Wales, Scotland, the Continent, Asia, Africa, and Australia. The aggregate horse-power supplied during 1890 in dynamos and motors for this purpose is very nearly 1,000 horse-power. In tram-car work, although no new lines have been laid down this year by the Company, they have made considerable progress in the general details of accumulator

Digitized by Google

work, and have successfully run their cars on the North Metropolitan Tramway Company's lines at Barking during the whole of the year. In the electric launch department during the past summer the Company had launches both on the Thames and on the Union Canal at Edinburgh during the late Exhibition. The total number of passengers carried at Edinburgh was 100,000, and the result commercially was thoroughly satisfactory. On the Thames some 12 launches were kept for hire, and although the season was a bad one, yet they were patronised by the public to a large extent. The general work of the Company during the past year was far in excess of that of the previous year, and shows a large increase in the demand for motors suitable for central stations, and motors for special machine tools have been in fair demand. A large number of dynamos for electric lighting have also been supplied by the Company, and several important installations have been carried out, amongst others may be mentioned Tatton Hall, Knutsford, the residence of Lord Egerton of Tatton. The prospect for 1891 is decidedly good, and the Company starts the new year with a large number of contracts in hand. Several important mining plants are now in course of erection, and others are in negotiation.

Messrs. Sharp and Kent.—This firm report a greatly increased business for the past year and good prospects for 1891. Amongst the principal orders the firm have executed may be mentioned the installation at the Houses of Parliament, the plant consisting of 160 horse-power boilers, engines, dynamos, pumps, and feed-water heaters, and 8 underground mains of 61/10, each containing a ton of copper. The whole of the plant was supplied, put down, erected, and started within three weeks, and ran successfully through the entire Session Messrs. Sharp and Kent have also supplied and erected for the Westminster Electric Supply Corporation at their St. John's Wharf station, Westminster, boilers of 600 horse-power, and engines and dynamos of 640 horse-power; and for the Windsor Hotel, Westminster, 160 horse-power engines and dynamos. A feature of the past year's work is the wiring for upwards of 15,000 lights. The firm have in hand engines and dynamos of 600 horse-power, pumps, tanks, &c., for the Corporation of Brighton, as well as the electrical apparatus in connection with measuring and testing instruments, switch-boards, resistances, &c., required under this contract.

Woodhouse and Rawson United.—This firm reports that in the beginning of the year they removed their head office from 11, Queen Victoria-street to extensive premises having frontages to 30, Cannon-street and 88, Queen Victoria-street respectively. Notwithstanding the size of these new premises, the Company have been obliged by business requirements to take the whole of an adjoining block of buildings. The new show rooms will be at 34, Cannon-street, and the secretary's office at 88, Queen Victoria-street. Among the developments may be mentioned the purchase and working of the engineering works at Kidsgrove, near Stoke-on-Trent, lately carried on by Messrs. Renshaw, King and Co. The important and growing business of electrical and steam launch building has been added to the other resources of the Company by the purchase of the business of Mr. W. S. Sargeant, of Chiswick. Branch offices have been opened in distant parts of the world, viz., Sydney, Melbourne, and Johannesburg, while other depôts such as Alexandria, Amsterdam, Barcelona, Bath, Bombay, Buenos Ayres, Cadiz, Cork, Dunedin, Hamburg, and Yokohama have been opened. At their Cadby Hall Works the Company have erected a huge new building to accommodate their increasing business in the manufacture of lamps and switches. In the contract department satisfactory progress has been made. In the Yorkshire districts forty installations have been carried out by the Bradford branch. In the Lancaster district, among the larger installations carried out by the Manchester branch, may be mentioned a 700-light plant for Messrs. Dobson and Barlow, Engineers, of Bolton. The central station lighting work at Barcelona has been planned out by the Company's engineers. In the supply department the turnover has increased 100 per cent. in the last twelve months. In the manufacturing department the Company holds a number of large contracts. Amongst the heavy electrical engineering work carried out at Kidsgrove may be mentioned complete electrical and mechanical plant for small central station at Palace-chambers, Westminster, and complete mechanical and electrical plant for the Woking central station. A considerable number of electrical launches have been built at the Company's yards at Chiswick, amongst them being the "Volt," and various launches from 28 to 31ft. long. For the English Government a very important departure has been made in building an electric pinnace capable of carrying 40 soldiers, another pinnace of this class having been already built for a steam yacht. As steel launch building requires special appliances, a special yard has been recently laid out for building steam launches of every description. The Company, after writing £7,000 off patents account, paid a dividend for the year of 15 per cent., put £25,000 to reserve fund, and carried forward over £16,000.

Telegraph Manufacturing Company (Limited).—The works have been extremely busy during the past twelve months. The gutta-percha wire made by this Company has been in such demand, that although the plant has been doubled, the supply has scarcely been able to keep pace with orders. It has been found necessary to erect new buildings for the battery and insulator departments and for the instrument department. The Helsby Works will be solely devoted to the electric light, telephone, and telegraph wires and cables.

Messrs. Poole and White.—This firm notify us that business is extremely active, necessitating in the near future increased manufacturing premises. They have, during the past year, added to their list of manufactures a number of articles in great demand. Their well - arranged catalogue contains exhaustive tables relating to electric wires and cables, and illustrated particulars of White's patent ceiling rose, the "Poolite," "Diamond,' and other switches, switch-boards (in which department Messrs. Poole and White have large orders on hand), safety junctions, cut-out blocks, White's patent "Simplex" wall socket, back blocks, lamp holders, shades, globes, and reflectors. The catalogue consists in all of thirty-two large quarto pages.

Messrs. O. Berend and Co.—This firm furnish the electrical trade with a variety of supplies, and report that during 1890 the demand for their special goods has been fairly active both for home and export trade. In the artistic fittings in bronze and wrought iron work, a growing demand is experienced, and for the electrical instruments, volt and ammeters, manufactured by Messrs. Hartmann and Braun, business is brisk. Messrs Berend have lately introduced a soldering lamp and automatic blowpipe for electric linemen, as well as a tool for easily and quickly trimming the ends of wires and removing the insulation without damage to the wire. Messrs. Berend report that the demand for German carbons, dynamos, and other supplies has largely increased during the year.

Mr. Carl Oppermann.—We are in receipt of the illustrated price list and particulars of the dynamos, &c., manufactured by Mr. Oppermann. The list is accompanied by a number of testimonials from users of the machine. Mr. Oppermann has recently completed an installation of the electric light at the works of the Fitch Typewriter-Company, in Clerkenwell-road, E.C., consisting of 80 incandescent 16 candle-power 110 volt lamps, distributed over the six-floor building. The lamps are fed by an upright-type self-regulating Oppermann dynamo, driven by a Griffin gas engine. Mr. Oppermann has also fitted up a plating department, wherein the parts of the type-writers manufactured by the Fitch Company are nickel-plated. The current for the plating machine is supplied by an Oppermann slow-speed plating dynamo.

Calendars, &c.—We have received a very useful and handsome memorandum tablet of china, with a movable weekly calendar, from Messrs. Appleton, Burbey, and Williamson, of 91, Queen Victoria-street, E.C.

——— Messrs. Crompton and Co. send us a blotting pad with calendar. A useful set of tables of weights and measures are arranged on the flap covering the calendar. Each year the calendars issued by this firm increase in usefulness.

# PATENT RECORD.

## APPLICATIONS FOR PATENTS.

**Note.**—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

December 13, 1890.

20,360. S. L. Tomkins, of the Electric Meter Company, Limited. London. Improvements in electric meters.

20,372. C. H. Cathcart. London. Improvements in electrical switches.

20,379. J. P. Bayly. London. Improved underground electric conduit (C. E. Loth, United States).

20,401. E. Andreoli. London. Improvements in the electrolysis of chloride and other solutions.

## COMPANIES' MEETINGS & REPORTS.

### The Eastern Telegraph Company (Limited).

The following is the report and accounts of the Directors of the Company for the half-year ended September 30, 1890, to be presented to the thirty-seventh half-yearly ordinary general meeting, to be held at Winchester House, Old Broad-street, E C., on Thursday, the 15th inst., at one o'clock:—

The revenue for the period amounted to £352,873. 11s. 1d., from which are deducted £91,723. 11s. 7d. for the ordinary expenses and £31,477. 17s. 9d. for expenditure relating to repairs and renewals of cables, &c., during the half-year. After providing £5,212. 8s. 2d. for income-tax, there remains a balance of £224,459. 13s. 7d., to which is added £2,484. 9s. 7d. brought from the preceding half-year, making a total available balance of £226,944. 3s. 2d.

From this balance there have been paid:—

| | £ | s. | d. |
|---|---|---|---|
| Interest on Debentures and Debenture Stock ... | 28,274 | 13 | 0 |
| Dividend on Preference shares........................ | 20,474 | 3 | 9 |
| Two interim dividends of 2s. 6d. per share each on ordinary shares ................................ | 100,000 | 0 | 0 |
| | £148,748 | 16 | 9 |

leaving a balance of £78,195. 6s. 5d., which is carried forward to the next account.

The revenue includes £33,455. 17s. 8d. dividends for the half-year upon the Company's shares in the Eastern and South African, the Black Sea, the Direct Spanish, and the African Direct Telegraph Companies.

The Directors learn that the negotiations referred to at the last general meeting with certain of the Australasian Colonies for effecting a reduction in the tariff will be speedily concluded, and the new rates will be brought into operation at an early date.

The Directors have decided, in view of a largely increased traffic with Australasia, to lay a triplicate line from Aden to Bombay, and have entered into a contract with the Telegraph Construction and Maintenance Company for the manufacture and laying of the cable early in the present year.

The new Red Sea cable connecting Suez, Perim, and Aden, referred to in the last report, was successfully laid by the contractors in November last. Arrangements have been made to take the direct Suez-Aden 1876 cable into Suakim, thus duplicating the Suakim-Suez section, and adding to the security of submarine telegraph communication with that port.

In accordance with the Articles of Association, two of the Directors, Sir John Pender, K.C.M.G., and the Marquis of Tweeddale, retire by rotation at this meeting, and, being eligible, offer themselves for re-election. The auditors, Mr. Henry Dever and Messrs. Welton, Jones, and Co. retire, and offer themselves for re-election.

### Woodhouse and Rawson United (Limited).

An extraordinary general meeting of this Company will be held at Winchester House, Old Broad-street, E.C., this day (the 9th inst.), at 12 o'clock noon, for the purpose of considering, and, if thought fit, passing the subjoined extraordinary resolutions:

1. *That the Directors be authorised to enter into such arrangement as they shall think advisable with the Liquidators of Woodhouse and Rawson (Limited), for the immediate or early repayment to such Liquidators of the sum of* £75,000, *or any part thereof, deposited with the Company on the terms that it should be retained till the* 1st *of July,* 1892, *as a Dividend Guarantee Fund.*

2. *That the capital of the Company be increased to* £550,000 *by the creation of* 40,000 *new shares of* £5 *each, of which* 20,000 *shares shall be Preference Shares, which shall be entitled to the same preferential dividend and rights, other than the benefit of the dividend guarantee fund, and shall be subject to the same conditions as and rank for all purposes* pari passu *with the existing issue of* 30,000 *Preference Shares of* £5 *each of the Company, the remaining* 20,000 *shares shall be ordinary shares, and shall be entitled to the same dividends and rights, other than the benefit of the dividend guarantee fund, and shall be subject to the same conditions as, and rank for all purposes* pari passu *with the existing* 40,000 *ordinary shares of the Company.*

Should the second of the above extraordinary resolutions be passed by the required majority, it will be submitted for confirmation as a special resolution to a second extraordinary meeting, which will be subsequently convened.

## NEW COMPANIES REGISTERED.

**Birmingham Telegraph Factory (Limited).**—This Company was registered on the 31st ult., with a capital of £50,000, in £10 shares, to carry on business as telegraph and telephone engineers and contractors, and manufacturers of appliances and apparatus. The subscribers are:—Harold Mason, M.R.C.S., Leamington; *E. W. Lancaster, Edgbaston, Birmingham, electrical engineer; P. C. Bytheway, Wednesbury; *J. Slater Lewis, Yardley, near Birmingham, telegraph engineer; Arthur Mason, Leamington; Wm. Fowler, 69, Temple-row, Birmingham, land agent; *G. V. Fowler, Longbridge, Warwick, electrical engineer. The number of Directors is not to be less than 2, nor more than 4; qualification, 50 shares; the

**NEW COMPANIES REGISTERED DURING DECEMBER.**—Among the new Companies registered at Somerset House during December, 1890, were the following:—

| | Capital. |
|---|---|
| Albert Hoster (Limited), £20 shares | 2,000 |
| Ateliers Hoster de St. Nicolas, £20 shares | 2,000 |
| Avon India-rubber Company, £5 shares | 50,000 |
| Birmingham Telegraph Factory Company (Limited), £10 shares... | 50,000 |
| Electric Stores (Limited), £1 shares | 15,000 |
| Foreign Electric Date and Time Stamp Company, £1 shares | 100,000 |
| London Metallurgical Company, £10 shares | 15,000 |
| New Zealand Electrical Syndicate (Limited), £10 shares | 30,000 |
| Practical Electro-plating and Enamelling Company, £5 shares | 2,000 |

**SOUTHERN RAILWAY OF PERU (LIMITED).**—Registered by Smiles, Ollard, and Yates, 15, Bedford row, W.C., with a capital of £2,600,000, in £1 shares. Object, to acquire, construct, repair, complete, equip, maintain, and work railways, tramways, telegraph and telephone lines in the Republics of Peru and Bolivia, and to acquire and exercise any rights in relation to the navigation of any lakes or rivers in those Republics, and for such purposes to acquire all or any of the rights of the Peruvian Corporation (Limited), or any other company or of any firm or person relating to any such means of communication, appliance, or rights, and to apply to the Peruvian or Bolivian or any other Government for any concessions or contracts; to carry into effect an agreement made December 29, 1890, between Charles Watson of the first part, John Larkin Thorndike of the second part, the Peruvian Corporation (Limited) of the third part, Thomas E. Webb (as trustee on behalf of this Company) of the fourth part, and Michael Paul Grace of the fifth part.

## CITY NOTES, &c.

**AUSTRIAN ELECTRICAL COMPANIES.**—The Anglo-Austrian Bank of Vienna and the firm of Siemens and Halske, of Berlin, have just formed three new electrical companies, with headquarters in the former city. The first is the Austrian General Electricity Company, constituted, with a capital of £312,000, for the purpose of constructing and working central electric light stations. The second is the Electric Tramway Company, with a capital of £312,000, for the making and working of electric tramways; and the Company have already acquired the Buda-Pesth electric tramway. The third is the International Compressed Air and Electricity Company, with the same amount of capital, and formed to work a concession obtained from the Vienna municipality for lighting the city by electricity.

**ALBERT HOSTER (LIMITED).**—This Company was registered on the 30th ult., with a capital of £2,000 in £20 shares, to take over the business of mechanical and electrical manufacturing engineer, carried on by Albert Hoster, at 51, Cannon-street. The subscribers are the same as in the Ateliers Hoster de St. Nicolas (Limited).

**ATELIERS HOSTER DE ST. NICOLAS (LIMITED).**—This Company was registered on the 30th ult., with a capital of £2,000 in £20 shares, to acquire, work, and develop the business of mechanical and electrical engineer carried on by Albert Hoster, of 51, Cannon-street, at St. Nicolas d'Aliermont, Department of Seine-Inférieure, France.

**BRAZILIAN SUBMARINE TELEGRAPH COMPANY.**—The receipts of this Company for the week ending January 2nd amounted to £4,668.

**CHANGE OF ADDRESS.**—The Empire Telephone Company has changed its offices from 60 to 171, Queen Victoria-street.

**CITY AND SOUTH LONDON RAILWAY.**—The receipts of this Company for the 14 days ended January 3rd amounted to £1,947.

**CUBA SUBMARINE TELEGRAPH COMPANY.**—The estimated traffic receipts of this Company for the month of December were £3,000, as compared with £2,995 in the corresponding month of last year.

**DIRECT SPANISH TELEGRAPH COMPANY.**—The traffic receipts of this Company for the month of December show a decrease of £57, compared with the corresponding period in 1889.

**DIRECT UNITED STATES CABLE COMPANY (LIMITED).**—The Board of Directors of this Company announce the payment of an interim dividend of 3s. 6d. per share, free of income-tax, being at the rate of 3½ per cent. per annum for the quarter ending December 31, 1890. The dividend is payable on and after the 21th instant.

**EASTERN TELEGRAPH COMPANY (LIMITED).**—The traffic receipts of this Company for the month of December, 1890, amounted to £58,058 as against £56,862 for the corresponding period of 1889, or an increase of £1,196.

**EASTERN EXTENSION TELEGRAPH COMPANY.**—The receipts of this Company for December amounted to £43,482, as against £40,362 in the corresponding period of last year, showing an increase of £3,120.

**ELMORE'S FRENCH PATENT COPPER DEPOSITING COMPANY (LIMITED).**—The share certificates are ready to be exchanged for allotment letters and all bankers' receipts.

**EXCELSIOR COPPER COMPANY (LIMITED)**—An extraordinary general meeting of this Company, held on Monday, confirmed the resolutions passed at a previous meeting winding-up the Company with a view to its reconstruction.

**GREAT NORTHERN TELEGRAPH COMPANY.**—The traffic returns of this Company are as follows:—Receipts in December, 1890, £23,600; 1st January to 31st December, 1890, £280,000; corresponding months, 1889, £274,800; corresponding months, 1888, £272,200.

**INTERNATIONAL OKONITE COMPANY (LIMITED).**—The Directors of this company have decided to pay on and after Thursday next an interim dividend of 8 per cent. on the paid up capital. This dividend is declared out of the profits of the company earned since the date of the company's registration (June 24, 1890). The notice issued by the Directors states that the profits, which were purchased by the company as from January 1st until the date of registration (£20,113), have been certified by Messrs. Price, Waterhouse, and Co. to be in excess of the sum estimated in the prospectus as likely to accrue, but the Directors are advised that this sum is not available for the purpose of the payment of dividend, which must be paid out of the actual earnings of a company The dividend now payable, after payment of interest upon debentures, is for the six months ended December 31st, and is at the rate of 8 per cent. per annum upon the preference shares and 10 per cent. per annum upon the ordinary shares of the company. The transfer books of the company will be closed from the 10th to 13th inst. inclusive. The Directors announce that the new factory at Newton Heath, Manchester, is progressing rapidly towards completion, and the machinery is nearly all ready for delivery. When this addition to the existing works comes to be fully developed, the Directors anticipate a large increase in the English business.

**PORTSMOUTH AND SOUTH HANTS ELECTRICITY SUPPLY COMPANY (LIMITED).**—At a meeting of this Company, held on December 30th, resolutions passed at a previous meeting, that the Company be voluntarily wound up, were confirmed. Mr. W. Edmonds, C.A., Portsea, was appointed liquidator.

**WEST COAST OF AMERICA TELEGRAPH COMPANY.**—The traffic receipts of this Company for the month ending December 31, 1890, amounted to £5,375.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY.**—The traffic receipts of this Company for the week ending January 2, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,747.

**WEST INDIA AND PANAMA TELEGRAPH COMPANY.**—The estimated traffic receipts for the half-month ended Dec. 31st show a decrease of £102, as compared with the corresponding period of 1889.

# THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

**VULCANISED FIBRE,**
PATENTED.

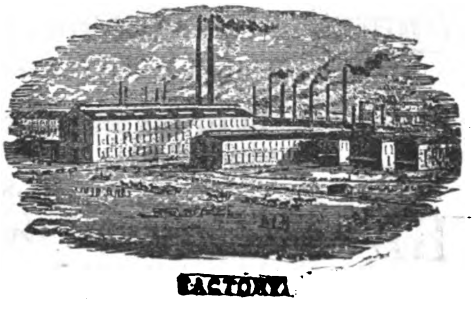
**This new material is supplied in two qualities, Flexible and Hard.**

**The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.**

**It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.**

**The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.**

**Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.**



FACTORY.

**FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.**

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 661.—Vol. XXVI. FRIDAY, JANUARY 16, 1891. Price Sixpence.

## NOTES.

One feature in Prof. Crookes' presidential address is its characteristic modesty. He does not waste a single breath in reminding his audience of some of his most important claims to scientific recognition. He passes by the spectroscopic discovery of the metal thallium—one of his own most brilliant researches—as though it were the discovery of any ordinary chemist. He ignores his own improvements of the Sprengel pump, which he described to the Physical Society in 1874; and the invention of the radiometer, which lay in the direct track to his discovery of radiant matter, is not once hinted at in this narrative of his researches.

The meeting of the Institution of Civil Engineers on Tuesday last, at which a Paper on "Auxiliary Engines in connection with the Modern Marine Engine," by W. H. Allen, was read, was followed by the first of a series of receptions. The rooms in No. 25, Great George-street, which adjoin the principal building, were thrown open, and a considerable number of very interesting exhibits were displayed, including dynamos and armatures illustrating the Paper which had just been read, a number of lighthouse-burners for gas, models of bridges, photographs, microscopes, &c. One should not look a gift horse in the mouth, and it is rarely, if ever, that those kindred societies and institutions who enjoy the privilege of using the rooms of the Institution have any cause for complaint. But the re-arrangement of the benches on a level instead of on a gentle slope seems to be a great mistake. It is not only more difficult to hear, but it is practically impossible for anyone but those on the first two rows to see any objects exhibited on the table, or any experiments carried out upon it. The Institution of Civil Engineers do not have so many experiments at their meetings as the Institution of Electrical Engineers, though objects of interest are not infrequently shown. From both the point of view of the audience and of the speakers, especially of those who take part in the discussion, the change must be very unsatisfactory; and we are sure that the case has only to be properly brought before the Council to ensure a speedy return to the old arrangement, which left little or nothing to be desired.

The Board of Trade have not been caught napping, as has been suggested, with respect to the twopenny fares of the City and South London Railway. Indeed, the only person who has made any mistake about the matter appears to be the correspondent to a financial contemporary, who discovered that "all railways shall run passenger trains at the Parliamentary fare of one penny per mile." As a matter of fact, the question was thoroughly discussed by the Parliamentary Committee, and it was decided that the novel method of uniform charges and abolition of classes were "sufficiently democratic" to warrant an exception being made to the above rule. With regard to the letter which will be found in our correspondence columns, the only point of difference between our esteemed correspondent and ourselves is as to what discount must be made in respect to the traffic returns of this line for the factor of "novelty." Our correspondent is inclined to make an allowance of some 40 per cent.; we are not. What the normal traffic will be cannot, however, be seen until the line has been in regular operation with a three-minute service for at least six months. The Company are well advised in not attempting to commence this quick service just at present; though it is obvious to anyone who has seen the generating plant that there need be but little difficulty on this score.

That the acquisition of the telegraphs by the United States Government is still within the range of practical politics may be seen from the number of opponents who think it necessary to keep on writing against every such scheme. The latest champion of the companies is Mr. Wiman, whose ideas on the subject were copied into the *Electrical World* of New York a week or two ago from Frank Leslie's *Illustrated Newspaper*. Mr. Wiman has gone into the subject pretty thoroughly, and we are not in a position to challenge his assertion that the Departmental Officials of the United States Government are inferior in capacity to the leading men who at present administer the telegraph companies' service. We have always admitted that a political system which requires every public servant to retire with his party after a four years' term of office is decidedly inimical to Governmental management of the telegraph, or of any other business whatsoever. But that is the affair of American citizens. When, however, Mr. Wiman supports his arguments by examples from this country, about which he evidently knows nothing, we have simply to remind him that the difference between the two countries in this relation is not so much one of population or of area, but of political life. The business affairs of the British nation are carried on quite independently of party, and would get along just the same if the Government changed hands every four hours, or never changed at all. It

Digitized by Google

is, perhaps, no use telling Mr. WIMAN that the telegraph service of this country is the swiftest, as well as the cheapest, in the world, or that whatever invention of value America has had to offer us we have long ago turned to the best account, or that the Americans on their part have been slow to adopt some of our most perfect appliances. He may be unable to believe all this; but he can hardly deny that the telegraph is an instrument of commerce, whereas the buying and selling of petroleum is commerce itself. Mr. WIMAN argues that if the Government buys up the telegraphs it might with just as much reason buy up all the oil wells. He might as well contend that because Governments do the letter carrying business, they ought to manufacture all the letter paper, or turn their hands to the making of paraffin lamps.

A CURIOUS commentary upon Mr. WIMAN'S disparaging remarks about the English Government telegraphs comes to us in our New York correspondent's letter this week. It appears that some recent fogs in the Middle and Western States almost completely crippled the telegraph lines; and on this our correspondent observes that "these phenomena may be more frequent with you in England, but they are almost unique here." The phenomena of fog and rain are indeed of frequent occurrence here; but interruptions on account of either would be almost unique.

THE two meters which are described in the present issue may be regarded as the latest achievements in the two classes of motor meters and pendulum meters. Those of the former class were perfectly useless until the method of compound winding was employed, by which a shunt coil gives just sufficient torque to overcome the friction while moving. If the friction of repose be only slightly higher than this, the meter will begin to register when a very small current passes through the main coils. Nor could they be considered to be in a practical form until the speed of the moving part had been considerably reduced. The pendulum meter, on the other hand, has been open to the disadvantage of requiring winding up, and to the difficulty so keenly felt by CHARLES V. of making the pendulums keep in synchronism. The adoption of the torsion principle not only diminishes the trouble of winding, but largely prevents any transmission of small impulses from one pendulum to the other, and does away with the necessity for careful levelling. This class of meter has a great advantage in the wide range within which it will work. It is a comparatively easy matter to invent meters which will record the current taken by one lamp up to ten or twelve, and there are a good many which will work from one to twenty, but beyond this few will go; and among those few will be found the meters of the future.

IN the December number of Wied. *Annalen* appears an interesting study of the phenomena of electric oscillations by Mr. LECHER, who has succeeded in introducing some improvements in one of Prof. HERTZ' experiments. The discs, which are opposed to the capacity plates of the primary oscillator, are connected with two long parallel wires. Across these a vacuum tube is placed as a delicate detector of the oscillations. The wires are also bridged across by one or more metal bars, whose position is adjusted till the vacuum tube indicates the greatest effect. The exact interpretation of some of Prof. HERTZ' experiments is still very obscure, but Mr. LECHER has followed the most satisfactory course, under the circumstances, by relying almost entirely on experiments for his guide. Starting with the assumption that the oscillations of electricity in a long wire are analogous to the sonorous oscillations of air in a tube, he has by numerous measurements with different lengths of wire and connecting bars arrived at consistent values for the wave length of the oscillations, and the velocity with which they travel. The result indicates that the velocity with which electric disturbances are propagated is very approximately the same as the velocity of light, not only in air, as HERTZ has previously shown, but also in metallic conductors. The method employed is remarkable for its freedom from extraneous disturbances, such as those caused by the presence of sparks: and the use of the vacuum tube, although not altogether novel, seems a very satisfactory feature of it.

**Ipswich.**—The Town Council has decided, by 13 votes to 7, to support the Provisional Order of Messrs. Laurence, Scott & Co.

**Transmitting Electric Signals to Montreal.**—The Greenwich authorities have found that the exact period of transmitting an electric signal to Montreal, Canada, is about $\frac{3}{4}$ of a second.

**Electric Light Mains in London.**—We shall publish in our issue of January 30th a map showing all the streets in the metropolis in which electric light mains have been laid.

**L'Elettricita.**—With the commencement of the year, our Milan contemporary, *L'Elettricità*, has become the official organ for the publications of the proceedings of the Italian Electrical Society.

**Royal Society.**—At the last meeting of this Society the following paper by Prof. J. J. Thomson was down for reading: "On the Rate of Propagation of the Luminous Discharge of Electricity through a Rarefied Gas."

**The Ferranti Effect.**—Mr. Swinburne is discussing the "Ferranti Effect" in a series of articles in *Industries*. When the series is completed we hope to have something to say on Mr. Swinburne's theory of the phenomenon.

**The Electric Lighting of the City.**—At the last meeting of Commissioners of Sewers it was moved that the question of the appointment of a permanent electrical engineer should be considered by the Streets Committee. This was agreed to.

**Hexham.**—A letter from the Northern Counties Electric Light and Power Supply Company, asking for permission to rent the water-power of the old water reservoir at Hexham as an auxiliary power, has been received by the Hexham Local Board.

**Hove.**—At their last meeting, the Hove Commissioners confirmed the proceedings of the Electric Lighting Committee, and the electric lighting of Hove will therefore be handed over to a company; Mr. R. E. Crompton acting as consulting electrical engineer to the Commissioners.

**The Brush Double Carbon Arc Lamp Patent.**—In the suit of the Brush Electric Company against the Fort Wayne Electric Company an injunction has just been granted restraining the defendants from manufacturing or selling the Wood clock-work double carbon lamp.

**The Post Office Magazine.**—This month's number is, we think, the best that has yet appeared, the articles and stories being varied in character and all of them interesting. The ghost story at the beginning is one of the cleverest we have ever read.

Digitized by Google

**The Paris Municipal Station.**—According to M. Paul Brousse, Chairman of the Electric Lighting Committee of the Paris Municipality, the expenses of the municipal central station at the Halles will amount in 1891 to £14,454, the receipts for the same period being estimated at £18,420.

**Underground Work in Chicago.**—According to Mr. F. E. Degenhardt, there is at present in successful daily operation in Chicago the following amount of underground wires:—Electric light cables, 404 miles; telephone cables, containing 6,080 miles of conductors; and telegraph wires, 650 miles.

**Institution of Civil Engineers.**—At the meeting of this Institution on Tuesday evening last, M. Carnot, the President of the French Republic, was elected by acclamation an honorary member. As a result of the ballot subsequently taken Lord Rayleigh became an honorary member, while 4 members, 31 associate members, and 2 associates were declared to have been duly elected.

**Types of Electric Meters used in London.**—According to the figures recently given by Mr. Frank Bailey, 1,573 electric meters are in use in London; of these 546 are Westinghouse meters, 508 Aron, 174 Ferranti-Wright, 136 Ferranti (mercury), 90 Hookham, 71 Lowrie-Hall, 34 Aubert, 14 Frager. Westinghouse meters thus comprise nearly 35 per cent. and Aron meters over 32 per cent. of the total.

**Mutual Telephone Company.**—It is announced by the *Manchester Guardian* that this Company will early next month open for traffic the first section of their Manchester Telephone Exchange, and that they hope to get to work in Liverpool very soon afterwards. Orders for between 1,600 and 1,700 instruments have been already obtained in Manchester, and a considerable number of orders have also been booked in Liverpool. Complete metallic circuits will be provided.

**Electric Transmission of Power in Spain.**—A few days ago an important plant for the transmission of energy by electricity was inaugurated at San Juan las Fonts, in the Province of Gerona, at the paper mill of Sres. Sucesores de Torras Hermanos, which receives 50 horse-power from a distance of about 2½ kilometers. The current is conveyed by copper wires of 8 millimeters diameter, suspended on porcelain insulators and posts. The turbines and electrical plant have been constructed by Sres. Planas, Flaquer, and Co., of Gerona.

**Honours for French Telegraph Officials.**—The Emperor of Russia has conferred the Grand Cordon of the First Class of the Order of St. Stanislas on M. de Selves, Director-General of the French Post and Telegraph Department. M. Baron, Director of Works, has received the Order of Grand Officer of the First Class of St. Stanislas; M. Ungerer, head of the telegraphic branch, has been given the Cross of Commander of the First Class of the Order of St. Stanislas, and M. Bordelongue has been made a Chevalier of the Order.

**Telegraphists' School of Science.**—On Wednesday afternoon Mr. W. H. Preece distributed at the General Post Office the medals, prizes, and certificates gained by the students of the Telegraphists' School of Science. The report showed that at the examination in technical telegraphy, held by the London Technical Institute, sixty-seven certificates were granted to the numerous schools throughout the kingdom, and of this number twenty-seven (or 40 per cent.) were awarded to the students of this school. Sixty-three per cent. of these certificates were first-class.

**Electric Cars and Snowstorms.**—The late unusually heavy snowstorms have, says the *Electrical Engineer* of New York, been very trying to the street car lines, but on the whole the electric cars have come through the ordeal very well, especially where the management of the road had been wise enough to include snow ploughs and sweepers in the equipment. Another point brought out by the visitation has been that the single-trolley roads have stood up much better than the double. It is reported that in Cincinnati the short-circuiting on the double-trolley road played havoc with the motors.

**Electric Street Railway Poles.**—At Passaic (N.J.) the objections of owners of property have led to the construction of the largest poles ever used for street railway work. The dimensions of the poles are as follows: Height, 35ft; length of arm, 32ft. 8½in.; height of arm above the ground, 20ft. 1½in. The poles are designed to carry 500lb. on the end of arm. The total weight of each pole is 2,000lb. The poles, although subjected to heavy strain, have remained, it is stated, perfectly erect. The track is on one side of the street, and owing to the above-mentioned objections the railway company was compelled to set the poles on the opposite side of the street, and throw an arm nearly 33ft. long right across.

**Woodhouse and Rawson United.**—A dinner was given to the staff of the head offices of this Company, at the Guildhall Tavern, on Tuesday evening last, Sir Rawson W. Rawson occupying the chair. More than 100 employés of the firm were present. In reply to the toast of his health, Mr. F. L. Rawson referred to the Pension Fund which had recently been established by the Board, and made reference to a profit-sharing scheme which the Board had in contemplation for the benefit of the employés. Mr. G. North, the general manager, announced that it was proposed to establish a library and reading-room at their new premises, 34, Cannon-street, E.C., and also that there would be given, on Friday evenings during the winter months, a series of free lectures on electrical subjects.

**West Metropolitan Tramways Company.** — The West Metropolitan Tramways Company, who were authorised in 1889 to construct additional tramways in Hammersmith, Chiswick, Acton, and Ealing, have deposited a Bill asking Parliament to extend, until August, 1893, the time originally granted for the construction of these lines. The Company there state that they are desirous of reconstructing their existing system in such a manner that all the tramways may be worked by electrical power, but that, owing to many unavoidable difficulties, the local authorities have not yet agreed to allow electrical power to be adopted. Owing to this delay on the part of the authorities in settling the terms upon which electricity may be used, the Company ascribe their failure to raise the required additional capital for these extensions.

**Platinum Residues.**—In the face of the present high price of platinum, says the *Chemical Trade Journal*, residues and "washes" of this metal are well worth working up. The old developing-baths for platinotype paper, odd bits of the paper itself, spoilt prints, &c., all may be reworked. Old developers may be treated with saturated solution of sulphate of iron—one part of the saturated solution to four parts of the developer will be about right. The mixture should be heated to boiling in a porcelain dish, and the precipitated metal collected on a filter. Bad prints, clippings, &c., of the paper should be placed on a tin or iron plate and burnt, the ashes collected and digested for some hours at 50-70° C. with *aqua regia*, and then the solution diluted with an equal volume of water, and the platinum precipitated with iron as above, or with ammonium, or formate of soda, or any other reducing agent.

**Arc and Incandescent Street Lighting in Paris.**—At a recent meeting of the Paris Municipal Council, M. Paul Brousse, in presenting the Electric Lighting Budget for the current year, stated that the police authorities had reported very favourably with regard to the arc lighting of the portion of the Avenue de Clichy, near the fortifications. According to the police, the arc lamps "have driven away the suspicious individuals who formerly stationed themselves at this part of the avenue, and since the adoption of this mode of lighting no nocturnal assaults nor serious accidents have been recorded." As to the incandescent lighting in the Rue Auber and the Rue des Halles, M. Paul Brousse is of opinion that it is too expensive, and suggests that it should cease, at any rate so far as the Rue Auber is concerned.

**The Duration of Telegraphic Currents.**—In a recent issue the *Zeitschrift für Elektrotechnik* remarks that a few figures with regard to the duration of currents used in telegraphy may be of interest. In ordinary Morse working the average duration of the signalling current may be taken at ·125 second; with the Hughes apparatus currents lasting only from ·04 to ·05 second are emitted, while with the Meyer multiplex apparatus currents having a duration of as little as ·007 second, and

with the Delany multiplex of ·002 second are sent to line. The lowest figure is, however, reached by the Wheatstone automatic, which, when transmitting at the rate of 600 words a minute, sends out 33,600 currents per minute, or 560 per second, each having, therefore, a duration of ·0018 second.

**Electricity in Mines.**—"We are officially advised," says the *Engineering and Mining Journal*, of New York, "that the contract for what will be the largest electric mine haulage plant has recently been given to the Edison General Electric Company by the Loyal Hanna Coal and Coke Company, of Philadelphia, Pa. This plant will consist of one locomotive, capable of delivering hourly 129 cars to the bottom of the shaft, each car containing 2½ tons of coal. This would make the output 300 tons of coal per hour, and a total work of 375 ton miles per hour; the gross weight of the trains to be hauled will be 120 tons. About 3,000 feet of gangway will be equipped with conductors at the start, but as the lengths of the gangways increase this will have to be increased to 10,000 feet, and the Company is then expected to put in a second locomotive of equal capacity to the one mentioned above."

**Festivities at Porthcurno.**—At Porthcurno, the cable station and Training College of the Eastern Telegraph Company, the usual Christmas festivities were indulged in by the members of the staff. On Boxing Night Mrs. Ash gave a general invitation to a dancing party, which was attended by almost the entire *personnel* of the staff, some few away on leave, and others necessarily on duty, being excepted. On the first day of the new year the members of the staff gave an "At Home," invitations being extended to a large number of friends in the neighbourhood. During the early part of the evening the auditorium of the Lecture Hall was tastefully arranged, and a series of amusements were provided by the "exiles" for their visitors. After supper, the "exiles" and their guests, numbering from sixty to seventy, returned to the hall, which had been cleared for dancing, and where the strains of the Penzance Town Band carried a very enjoyable time into the early hours of the morning.

**Benjamin Franklin's Will.**—The bequest by which Benjamin Franklin left to each of the cities of Boston and Philadelphia, in 1790, the sum of £1,000 sterling to be loaned out at 5 per cent. to deserving young married artificers is being disputed in the courts by his descendants. In Boston the fund has reached $400,000 and in Philadelphia $100,000. The contest is based upon several grounds, the most important of which is what is known as the rule of perpetuities in common law. The law does not provide for the vesting of a legacy beyond the period of 21 years after the lifetime of the legatee, except funds devoted to charity. It is distinctly alleged that Franklin's plan did not contemplate charity from the fact that interest was charged on the loans. The claim is also raised that the purpose of the testator has not been fulfilled, owing to the apathy and negligence of the trustees, both in Philadelphia and Boston.

**The Comparative Efficiencies of Dynamos and Thermopiles**—Two easily-remembered figures permit us, says the *Bulletin de l'Electricité*, to form a clear idea of the relative value of a thermopile and a dynamo driven by a gas engine as an apparatus for the transformation of the thermic energy of combustion of coal gas into electrical energy. In all tests of thermopiles heated by gas the consumption has up to the present exceeded 3,000 litres per kilowatt per hour (105 cub. ft. per kilowatt-hour). A good gas engine consumes from 600 to 700 litres (21 to 23·5 cub. ft.) per B.H.P., and for this consumption we may obtain 600 available watts from a dynamo heaving 85 per cent. efficiency, and this is equivalent to 1 litre (·035 cub. ft.) per watt-hour, or 1 cubic metre (35·3 cub. ft.) per kilowatt-hour. Hence for a given amount of electrical energy a good thermopile requires three times as much gas as a dynamo driven by a gas engine. We may add that no commercial thermopile exists of more than 10 or 12 watts, while 100 horse-power gas engines are now constructed.

**The Telephone at Plymouth.**—The subject of telephonic signalling from ships to the shore has come in several forms, and on frequent occasions, before the Plymouth Chamber of Commerce and its committees. Permission has been obtained for the signalmen of the Breakwater Fort to telephone to the agents of the various lines of mail steamers the arrival of such steamers in the Sound when, owing to the thick weather, they are not observable from the shore; and, as we have already announced, it has been arranged for all Government offices in the Port, including the office of the Queen's Harbourmaster, and also the Chamber of Commerce, to be connected with the Exchange. The permission obtained for the Telephone Exchange to be connected with the Coastguard signal station at Rame Head, with a view to merchant ships and ships of the Navy being reported, and signals exchanged with them, from that commanding position, will be made use of as soon as the necessary quarters have been provided for the extra signalmen. The capabilities of the telephone in this direction have, it will thus be seen, been fully taken advantage of at Plymouth.

**Railway Signalling.**—Under the auspices of the Inventors' Institute, a lecture was delivered on Wednesday night, at Lonsdale Chambers, Chancery-lane, on "The Electric Locking and Block System in use on the City and South London Electric Railway," by Mr. C. E. Spagnoletti. The lecturer at the outset gave a brief account of the construction of the railway in question. At the present time, he remarked, the trains were run every six minutes, but the traffic was so enormous—thousands of passengers having to be turned away at certain hours of the day—that the Company were going to run the trains every three minutes. Having described the electrical block system in use on several of the most important railways—the Great Western amongst others—he proceeded to explain, by use of diagrams, the mode of signalling on the City and South London Electrical Railway. Various instruments with plungers were manipulated, showing the method by which signalmen checked each other. The most ingenious feature, however, of the system appeared to be a treadle which was worked automatically by the engine, and so locked the levers that, until the train had passed a certain spot, the signals could not be dropped.

**The Schiseophone.**—Under the auspices of the South-Eastern Railway Company, a demonstration of the capabilities of the schiséophone (see *The Electrician*, Vol. XXV., p. 386) was given on Wednesday last by Captain de Place, at the Charing Cross Hotel, in the presence of several members of the Ordnance Committee and other Government officials. Among those present were Sir Frederick Bramwell, Sir Benjamin Baker, General Hay, Colonel Watkin, R.A., Colonel Bainbridge, R.A., Colonel the Hon. Reginald Talbot, Captain Domvile, R.A., Colonel Surtees, Captain Bridge, R.N., Dr. William Anderson, Sir Edward Watkin, Sir Myles Fenton, Captain H. F. Gye, R.N., Mr. Stirling, C.E., Mr. Brady, and Mr. Wainwright. Mr. Stirling, the Company's locomotive superintendent, had previously has several samples of steel, wrought iron, and cast iron prepared with hidden flaws known only to himself. The first sample tested by Captain de Place he pronounced to be bad metal throughout, which Mr. Stirling stated he knew it to be. Other samples were tested, and the flaws localised by means of the apparatus. On breaking some of the bars of wrought and cast iron, the internal flaws—the localities of which were known to Mr. Stirling by his private mark—were found to have been correctly localised by Captain de Place. On the other hand, it has to be stated that some bars were broken at points where the apparatus indicated a flaw, but where the metal proved to be perfectly sound.

**The Magnetisation of Iron by the Leyden Jar Discharge.**—The magnetising power of a Leyden jar discharge, although a somewhat complex quantity, depends for one thing on its duration. Thus, if a Leyden jar is successively given two equal charges, and in one case discharged very suddenly and in the other comparatively slowly, the magnetising effect of the latter discharge will probably be greater than that of the former. This is due to the fact that the more rapid discharge produces more powerful superficial eddy currents which effectually shield the interior portions of the bar to be magnetised. The following experiment of M. A. Marianini, which was described in a recent number of the *Nuovo Cimento*, bears on this point. In the discharge circuit of a condenser M. Marianini placed an air gap and a magnetising helix. The iron to be magnetised consisted of a glass tube filled with iron filings. He observed the devia-

Digitized by Google

tions of a magnetometer needle, due to the presence of the iron filing cylinder, after the iron had been subjected to various discharges. The air gap was at first ½mm., and after passing ten discharges the needle only deviated by 4deg. With a sparking distance of 3mm., four successive discharges resulted in a magnetisation strong enough to cause the needle to deviate 32° 30′. With a 7mm. gap, and after only one discharge, there was a deviation of 53° 30′. The same air gap was then used, but the resistance of the circuit was this time increased by introducing a tube containing water; deviations of 77° 30′ and 79° were then attained.

**New Target Board at the Chicago Telephone Exchange.**—For some time past the operators at the Chicago Telephone Exchange have been so pressed with business that it has been found impossible for them to answer in their proper order. With a view of relieving the regular operators of the duty of watching for "ring offs" a "target" board, says the *Western Electrician*, was designed. A call first comes to the regular operator on the main multiple switch-board. This operator, it will be assumed, finds the line wanted busy. She then records the number wanted on slate, and telephones it to a ticket maker at the target board. This ticket maker is given the operator's number, the number wanted, and the number of the line calling. The ticket maker records the call on a small strip of cardboard, placing the numbers in the above order. This ticket is passed from the ticket maker to an operator whose duty it is to watch for lines to become disengaged. The last-named operator has in front of her terminals of tap wires from every line running into the exchange. There are also in front of her several rows of annunciators or targets. These targets appear black when the busy line is cut out of service by the main switch-board operator. The targets are white when the line is in service. When the target-board operator receives a ticket she first places it in a little brass pocket, and then takes the plug corresponding with that particular pocket and inserts it into the socket belonging to the tap wire of the line wanted, say "1,446." When "1,446" becomes disengaged on the main board, the target shows black. The target-board operator then plugs in on a special talking wire, and tells the operator that the line wanted, "1,446," is not "busy." The main switch-board operator then takes "1,446," and the target again shows white. So long as this is so, the line is left undisturbed. When black shows again, a new ticket is taken up. This operation is continued until all tickets waiting for "1,446" are disposed of. The arrangement of circuits is such that when the line is connected with the target-board, a test-current is thrown on this line, so that operators on the main switch-board will not take it during the interval of time consumed in making the change.

**Arc Lighting in the States.**—Although it is pretty generally known that arc lighting, especially for street lighting, has a far greater vogue in the United States than with us, we think the scale on which it is actually carried out is not fully realised. The following figures from the *Electrical World* of New York, relating to the arc-light stations of the Municipal Electric Lighting and Power Company of St. Louis and of the Chicago Municipality, give a good idea of the manner in which arc lights are made use of in the States. In December, 1888, tenders were advertised for the public lighting of St. Louis, and on March 9, 1889, the contract for 2,310 2,000 candle-power arcs was awarded. In nine months from then everything was ready. The plant comprises 19 Rohan boilers of a total capacity of 6,500 horses, six 600 horse-power Hamilton-Corliss engines, and 53 60-light Wood dynamos. The boilers are in a separate house, 110ft. by 60ft. The station house is a four-floored building, 110ft. by 100ft. and 65ft. high. On the ground floor are the engines, while on the second floor is the counter-shafting, and on the third floor the dynamo plant. At present there are 88 circuits, having a total length of nearly 900 miles. One circuit is 19½ miles long, and contains 62 lights. The wires are all run overhead on white cedar poles, 10,000 of which are used. In August, 1890, the St. Louis Municipal Company acquired the St. Louis Illuminating Company, which had a capacity of 1,500 arc lights; also the Heisler incandescent lighting plant, with its 5,000 30 candle-power lamps. Since that date some of the plants have been transferred to the new station and the old stations closed, and as soon as a sufficient number of Wood dynamos are received to carry the increased load all the other stations will be abandoned, thus concentrating all the arc lighting under one roof. At the present moment more than 3,500 arc lights are controlled from this one station. Since August 600 additional lights have been ordered by the municipal authorities. On Christmas Eve the fourth electric light station of the city of Chicago was put into service. The initial capacity is 500 lights, while the building and machinery have been so designed that current can be supplied for a total of 900 lights. The four station of the city now have the machinery required to supply 4,000 lamps, 3,000 being in nightly service.

**Non-Conductors for Steam Pipes.**—The following table is taken from a report by Prof. John M. Ordway, then of the Massachusetts Institute of Technology, to the Boston Manufacturers' Mutual Fire Insurance Company. The materials which may be considered wholly free from the danger of being carbonised or ignited by slow contact with pipes or boilers are denoted by a (†). Those which are more or less liable to be carbonised are denoted by a (*). Careful experiments were made with various non-conductors, each used in a mass 1in. thick placed on a flat surface of iron kept heated by steam to 310deg. F. The following table gives the amount of heat, reckoned in pounds of water heated 10deg. F., transmitted per hour through each kind of non-conductor 1in. thick, the unit of area being one square foot of covering. The substances numbered in Roman figures were actually tried as coverings for 2in. steam pipe :—

| | Substance 1in. thick. Heat applied 310°F. | Pounds of water heated 10°F. per hour through 1 sq. foot. |
|---|---|---|
| *1. | Loose wool | 8·1 |
| *2. | Live geese feathers | 9·6 |
| *3. | Carded cotton | 10·4 |
| *4. | Hair felt | 10·3 |
| *5. | Loose lampblack | 9·8 |
| *6. | Compressed lampblack | 10·6 |
| *7. | Cork charcoal | 11·9 |
| *8. | White pine charcoal | 13·9 |
| *9. | Anthracite coal powder | 35·7 |
| †10. | Loose calcined magnesia | 12·4 |
| †11. | Compressed calcined magnesia | 42·6 |
| †12. | Light carbonate of magnesia | 13·7 |
| †13. | Compressed carbonate of magnesia | 15·4 |
| †14. | Loose fossil meal | 14·5 |
| †15. | Crowded fossil meal | 15·7 |
| †16. | Ground chalk (Paris white) | 20·6 |
| †17. | Dry plaster of Paris | 30·9 |
| †18. | Fine asbestos | 49·0 |
| †19. | Air alone | 48·0 |
| †20. | Sand | 62·1 |
| †XXI. | Best slag wool | 13·0 |
| *XXII. | Paper | 14·0 |
| *XXIII. | Blotting paper wound tight | 21·0 |
| *XXIV. | Asbestos paper wound tight | 21·7 |
| *XXV. | Cork strips bound on | 14·6 |
| *XXVI. | Straw rope wound spirally | 18·0 |
| *XXVII. | Loose rice chaff | 18·7 |
| †XXVIII. | Paste of fossil meal with hair | 16·7 |
| †XXIX. | Paste of fossil meal with asbestos | 22·0 |
| †XXX. | Loose bituminous coal ashes | 21·0 |
| †XXXI. | Loose anthracite coal ashes | 27·0 |
| †XXXII. | Paste of clay and vegetable fibre | 30·9 |
| XXXIII. | Magnesia covering (Sample I.) | 15·0 |
| XXXIV. | ,, ,, (Sample II.) | 20·0 |

"Magnesia covering," it may be mentioned, consists of carbonate of magnesia with a small percentage of good asbestos fibre. There are some mixtures of two materials which may be quite safe, although consisting in part of substances which may be carbonised. It must also be considered that a covering for a steam pipe or boiler should have some strength or elasticity, so that when even put on loosely, and holding a great deal of entrapped air, it may not be converted into a solid condition by the constant jar of the building, and then becoming rather a quick conductor. This warning may be applied especially to what is called "slag wool." Any suitable substance which is used to prevent the escape of steam heat should not be less than an inch thick.

## WILLIAM CROOKES, F.R.S.

Among contemporary men of science, few, if any, can present a more distinguished and varied career of research and discovery than the newly elected President of the Institution of Electrical Engineers, William Crookes. Though belonging by parentage, like Faraday, to Yorkshire, he was born in London in 1832, just in time, as he says, to escape having his mind ossified by examinations. His tendency to experimental science led him, when a boy, to the then comparatively virgin field of photography. In 1848 he entered the Royal College of Chemistry, as a pupil of the illustrious Dr. Hofmann. Here, at the early age of seventeen, he gained the Ashburton Scholarship. After two years' study he became first the junior and then the senior assistant to Dr. Hofmann. In 1854 he was appointed to superintend the Meteorological Department of the Radcliffe Observatory at Oxford. In the following year he became Teacher of Chemistry at the Science College, Chester. In 1859 he founded the *Chemical News*, of which he is still the proprietor, and which remains the organ of chemical science in this country. In 1864 he became editor also of the *Quarterly Journal of Science*, which he conducted down to 1880.

Prof. Crookes entered upon original research whilst still at the Royal College of Chemistry, his first results being a Paper on the Seleno-cyanides, which he communicated to the Chemical Society in 1851, and which appeared in the Journal of the Society in the same year. From this Paper, the greater part of the author's subsequent researches, multiform as they may seem, follow in legitimate filiation. His investigations on the compounds of selenium led him, in 1861, to examine certain residues from the sulphuric acid works of Tilkerode, where he met with a then unknown substance which, on thorough scrutiny, proved to be the new metallic element thallium. In June, 1862, and in February, 1863, he submitted to the Royal Society an elaborate account of the newly discovered element, its sources, distribution, the methods for its extraction and purification, as well as of its characteristics, physical and chemical. He showed its occurrence in various kinds of iron and copper pyrites, in crude sulphur as well as in flue dusts. His election as a Fellow of the Royal Society followed the same year. In 1864 he presented to the Chemical Society, of which he had been a Fellow since 1850, an exhaustive account of thallium embodying both his own researches and those of others, and including tables of the qualitative and quantitative reactions of this metal. This research necessitated delicate spectroscopic investigations, and thus led Prof. Crookes to the study of the so-called "rare earths," which has already proved so fruitful in his hands.

In 1865 he invented an improved process for the extraction of gold and silver from their ores, based on the use of sodium amalgam in place of pure mercury. We may mention that he has recently devised a further improvement in the treatment of refractory gold ores by submitting them to the action of an alternating electric current whilst in contact with mercury cyanide or other mercurial salts. In the year following he was appointed by the Government to experiment and report on the use of disinfectants for arresting the spread of the cattle-plague (rinderpest), which was at that time ravaging many parts of England and Scotland, and occasioning widespread alarm. In 1871 he was appointed a member of the English expedition to Oran, with the object of conducting a spectroscopic examination of the phenomena manifested during a total eclipse of the sun. In the following year he presented to the Royal Society a full account of his experiments for determining the atomic weight of thallium. Amongst other precautions adopted to insure accuracy, we may mention that he executed the necessary weighings by means of a balance which admitted of being manipulated in a vacuum.

In the same year he began his investigations on "Repulsion Resulting from Radiation." To this question his attention had been drawn in consequence of observations made when weighing heavy pieces of glass apparatus in his vacuum balance whilst determining the atomic weight of thallium. He communicated a memoir on this subject to the Royal Society in December, 1873, and between that time and 1880 he produced eight other Papers on collateral questions. These phenomena are manifested by means of the radiometer, otherwise known as the "light-mill." This instrument is capable of serving to measure the intensity of solar radiations, though not, it must be remembered, of light alone.

In 1875 Prof. Crookes received from the Royal Society a Royal Medal in recognition of his chemical and physical researches. In 1876 he was elected a Vice-President of the Chemical Society, and in the following year he became a member of the Council of the Royal Society. In 1877 he was remarkably active. He devised the Otheoscope, a modified form of the radiometer, and continued the study of repulsion derived from radiation, presenting his results to the Royal Society. He had succeeded in obtaining a vacuum so nearly approaching perfection that the pressure in it is only 0·4 millionth of an atmosphere. This result was effected by means of an improved Sprengel pump. The study of these high vacua led to a two-fold result: on the one hand it was found that at such extreme states of rarefaction gases lose their ordinary properties and pass into a fourth or ultra-gaseous state which Prof. Crookes has designated as that of "Radiant Matter." On the other hand, they rendered the electrical glow lamp a practical possibility. Prof. Crookes's house in Kensington-park Gardens, electrically lighted in 1881, was, we believe, the first house in London fitted up with the electric light. It may be interesting to state that the wires were chiefly laid with his own hands. To meet the difficulty of obtaining carbon filaments for the glow lamps not possessing the structure of the material from which they were made, Prof. Crookes dissolved cellulose in a strong solution of ammonium-copper sulphate, dried up the solution into sheets, dissolved out the copper, and used the horn-like material remaining for filaments. The lamps in the inventor's house fitted with such filaments remain still in good working condition. In 1881 he acted as a juror at the International Exhibition of Electricity in Paris. His system of lamps was, of course, debarred *ex officio* from competing, but his fellow-jurors remarked in their award on the four systems of lamps before them, that:—"None of them could have succeeded had it not been for those extreme vacua which Prof. Crookes has taught us to manage." The "Crookes' incandescent lamp" has, for a variety of reasons, not come into general use. The Company which undertook their manufacture had not sufficient capital to produce them on the large scale. Another company took the invention up, but further operations were stopped by the judicial decision in the Edison-Swan *v.* Brush case. We are not yet sufficiently removed from the days when a judge could rule that "*in a liberal construction, copper is tin.*"

In 1880 the French Academy of Sciences conferred upon Prof. Crookes an extraordinary prize of 3,000fr. and a gold medal in appreciation of his researches in Molecular Physics and on Radiant Matter.

On three successive occasions, namely, in 1877, 1878, and 1883, Prof. Crookes was selected by the Royal Society to deliver the Bakerian Lecture. On the first occasion he discussed the "Illumination of Lines of Molecular Pressure and the Trajectory of Molecules," his discourse being generally regarded as a model of deep thought and extreme experimental skill. His second Bakerian Lecture summarised his experiments and observations of "Radiant Matter." His third Bakerian Lecture, delivered on May 24, 1883, was devoted to "Radiant Matter Spectroscopy: A New Method of Spectrum-Analysis." This naturally leads to his researches on the rare earths, with which he has been engaged for several years, and which promise to lead to most important results. On attacking yttria by the process of "fractionation," he finds that it is resolved into at least five elements, possibly more, and there is no certainty that this analysis has reached completion. The new elements, or as Prof. Crookes calls them provisionally, "meta-elements," differ more in their physical than in their chemical properties. It is especially remarkable that substances which have been

Digitized by Google

found capable of decomposition may still possess a definite atomic weight. On studying closely the phenomena of these rare earths, Prof. Crookes has been led to the conclusion that the bodies which have generally been accepted as elements are not primordially distinct or independent, but have been formed by a process of evolution remotely analogous to that which we now recognise as having been at work in the formation of organic species. These views, a forecast of the "Chemistry of the Future," were given to the world in the presidential address which Prof. Crookes delivered before the Chemical Section of the British Association at the Birmingham meeting, under the title "The Genesis of the Elements." He further developed the same subject in his Presidential addresses to the Chemical Society in 1888 and 1889, and it constitutes without doubt his grand contribution to the philosophy of the science. In the experiments which pointed to these conclusions electricity has constantly been appealed to for the diagnosis of the new bodies encountered. In 1885, the Society of Arts awarded him a gold medal "for his improvements in apparatus for the production of high vacua, and for his invention of the radiometer." In 1888, he was awarded by the Royal Society the Davy Medal, for "his investigations on the behaviour of substances under the influence of the electric discharge in a high vacuum.

The contributions of Prof. Crookes to the literature of science have been both numerous and important. We are indebted to him for the "Third Report of the Cattle Plague Commission;" for a book on "The Manufacture of Beetroot Sugar in England" (1870), "A Handbook of Dyeing and Calico Printing" (1874), "Select Methods in Chemical Analysis" (1873; 2nd edition 1886). A manual of "Dyeing and Tissue Printing," being one of the technological handbooks prepared for the examinations of the City and Guilds of London Institute (1882). In conjunction with Prof. Odling and Dr. Tidy, he issues reports on the composition and quality of the water supplied to London (1881—1890). He has also written a "Solution of the Sewage Question," and "The Profitable Disposal of Sewage." He has edited the English version of Kerl's "Treatise on Metallurgy," and the three last editions of Mitchell's "Manual of Practical Assaying. He has translated into English and edited Reimann's "Aniline and its Derivatives;" Wagner's great work on "Chemical Technology" (a second edition of which is in course of preparation); Auerbach's "Anthracene and its Derivatives;" and Ville's "Artificial Manures," the second edition of which appeared in 1882. A list of the memoirs which he has contributed to the journals of the Royal and the Chemical Societies would far exceed our imits.

In all public questions in which science is concerned he has taken a prominent and a useful part. He is recognised as an authority on sanitary reforms, especially as regards the purification of sewage and the improvement of the condition of rivers. He has continually, and so far successfully, opposed the adoption of the arbitrary "proposals" of the Rivers Pollution Commissioners, and he sees no ground for the discontinuance of the present water supply of London. In leaders and reviews he has steadily condemned the system of examinations prevalent in England as calculated to destroy original thought. He is one of the signatories of Mr. Auberon Herbert's "Protest against the Sacrifice of Education to Examination." Wherever the claims of science or the rights of scientific men are neglected, Prof. Crookes is always ready to speak out. His career conveys an important lesson for the student. It is not merely the exceptionally suggestive character of his mind and his promptitude in appreciating every phenomenon presenting itself which have enabled Prof. Crookes to carry out such a quantity of important work. He possesses that "infinite capacity for taking pains" and that methodical spirit, without which genius and learning are thrown to waste. Every research in progress and in particular every result is duly recorded in a special note book. References to any work by other scientists bearing on the same or collateral subjects are registered, and every book in his extensive library, and every document in the pigeon-holes of his work-table is carefully indexed for reference. Without the economy of time and energy thus effected not half of his work could have been accomplished.

## INSTITUTION OF ELECTRICAL ENGINEERS.

PRESIDENTIAL ADDRESS OF PROF. WILLIAM CROOKES, F.R.S.

### Electricity in Transitu: from Plenum to Vacuum.

*Introduction.*

Whilst steadily bearing in mind that I have the honour to address a Society, not only of physicists, but of Electrical Engineers, I shall not, I hope, be out of order in venturing to call your attention to a purely abstract phase of electrical science. Numberless instances show that pure research is the abundant source from which spring endless streams of practical applications. We all know how speculative inquiry into the influence of electricity on the nervous systems of animals led to knowledge of current electricity, and ultimately to the priceless possession of the telegraph and the telephone. The abstract study of certain microscopic forms of parasitic vegetable life has enabled us to give to fermented solutions of sugar the exact flavour and aroma of the most highly prized wines, and probably, ere long, will put us in a position to increase at will the fertility of the soil. In a different direction the same class of abstract researches applied to medical science has brought us within measurable distance of the final conquest over a large class of diseases hitherto incurable; and without egotism I may, perhaps, be allowed to say that my own researches into high vacua to some extent have contributed to the present degree of perfection of the incandescence lamp. Surely, therefore, whilst eagerly reaping and storing the harvest of practical benefits, we must not neglect to scatter more seed for future results, perchance not less wonderful and valuable.

In another respect I deviate to some extent from the course taken by many of my predecessors. I am about to treat electricity, not so much as an end in itself, but rather as a tool, by whose judicious use we may gain some addition to our scanty knowledge of the atoms and molecules of matter, and of the forms of energy which by their mutual reactions constitute the universe as it is manifest to our five senses.

I will endeavour to explain what I mean by characterising electricity as a tool. When working as a chemist in the laboratory, I find the induction spark often of great service in discriminating one element from another, also in indicating the presence of hitherto unknown elements in other bodies in quantity far too minute to be recognisable by any other means. In this way chemists have discovered thallium, gallium, germanium, and numerous other elements. On the other hand, when examining electrical reactions in high vacua, various rare chemical elements become in turn tests for recognising the intensity and character of electric energy. Electricity, positive and negative, effect respectively different movements and luminosities. Hence the behaviour of the substances upon which electricity acts may indicate with which of these two kinds we have to deal. In other physical researches both electricity and chemistry come into play simply as means of exploration.

In submitting to you certain researches in which electricity is used as a tool, or as a means of bringing within scope of our senses phenomena that otherwise would be unrevealed, I must for a moment recall to your minds the now generally accepted theory of the constitution of matter.

*Kinetic Theory of Gases.*

Matter, at its ultimate degree of extension, is conjectured to be not continuous, but granular. Maxwell illustrates this view as follows:—To a railway contractor driving a tunnel through a gravel hill, the gravel may be viewed as a continuous substance. To a worm, wriggling through gravel, it makes all the difference whether the creature pushes against a piece of gravel or directs its course between the interstices. To the worm, therefore, gravel seems by no means homogeneous and continuous.

With speculations as to the constitution of liquid and solid matter I need not trouble you, but will proceed at once to the third or gaseous state of matter.

The kinetic theory of gases teaches that the constituent molecules dart in every possible direction with great but continually varying velocities, coming almost ceaselessly in mutual

Digitized by Google

collision with each other*. The distance each molecule traverses without hitting another molecule is known as its *free path*; the average distance traversed without collision by the whole number of molecules of a gas at any given pressure and temperature is called the *mean free path*. The molecules exert pressure in all directions, and are only restrained by gravitation from dissipating themselves into space. In ordinary gases, the length of the mean free path of the molecules is exceedingly small compared with the dimensions of the vessel, and the properties we then observe are such as constitute the ordinary gaseous state of matter, which depend upon constant collisions. But if we greatly reduce the number of molecules in a given extent of space the free path of the molecules under electric impulse is so long that the number of their mutual collisions in any given time in comparison with the number of times they fail to collide may be disregarded. Hence, the average molecule can carry out its own motions without interference. When the mean free path becomes comparable to the dimensions of the containing vessel, the attributes which constitute gaseity shrink to a minimum, the matter attains the ultra-gaseous or "radiant" state, and we arrive at a condition where molecular motions under electrical impulse can easily be studied.

The mean free path of the molecules of a gas increases so rapidly with progressive exhaustion, that whilst that of the molecules of air at the ordinary pressure is only 1-10,000th of a millimetre, at an exhaustion of a hundred-millionth of an atmosphere—a point (which with present appliances, is easy to attain) corresponding to the rarefaction of the air 90 miles above the earth's surface—the mean free path will be about 30ft.; whilst at 200 miles above the earth it will be 10,000,000 miles, and millions of miles out in the depths of space it will become practically infinite. I could go on speculating in spite of Aristotle, who said:—"Beyond the universe there are neither space, nor vacuum, nor time."

In discussing the motions of molecules we have to distinguish the *free* path from the *mean free path*. Nothing is yet known of the *absolute* length of the free path nor of the *absolute* velocity of a molecule. For anything we can prove to the contrary, these values may vary almost from zero to infinity. We can deal only with the *mean* free path and the *mean* velocity.

### *The Vacuum Pump.*

As most of the experiments I put before you to-night are connected with high vacua, it is not out of place to refer to the pump by means of which these tubes are exhausted. Much has been said lately in recommendation of the Geissler pump and its many improvements, but I am still strongly in favour of the Sprengel, as with it I have obtained greater exhaustion than with any other. I should like to point out that the action does not stop when we cease to see air specks passing down the tubes, but continues long after this point has been passed. Neither is the non-conducting vacuum, so easily obtained by the Sprengel pump, due in any way to the presence of mercury vapour, since non-conduction can be obtained just as rapidly when special precautions have been taken to keep mercury vapour out of the tubes.

One of the great advantages of the Sprengel pump over all others lies in the fact that its internal capacity need not exceed a few cubic centimetres, and there is, therefore, much less wall surface for gases to condense upon. I have brought the very latest modification of this form of pump here to-night, and you will have an opportunity of seeing it in action and of measuring with the McLeod gauge the rarefaction it produces.*

### *The Passage of Electricity Through Rarefied Gas.*

The various phenomena presented when an induction spark is made to pass through a gas at different degrees of exhaustion point to a modified condition of the matter at the highest exhaustions. Here are three exactly similar bulbs, the electrodes being aluminium balls, and the internal pressures being respectively 75 mm., 2 mm., and 0·1 mm. If I pass the induction current in succession through the bulbs, you will perceive in each case very different luminous phenomena. Here is a slightly exhausted tube (Fig. 1), like the first in the series just exhibited (75 mm.), the induction spark passes from one end to the other, A, B, and the luminous discharge is seen as a line of light, acting as a flexible conductor. Under the tube I have an electro-magnet, C, and on making contact the line of light dips in the centre down to the poles of the magnet, and then rising again proceeds in a straight line. On reversing the current the line of light curves upwards. Notice that the action of the magnet in this case is only local.

In a highly exhausted tube the action is quite otherwise. Such a tube is before you (Fig 2), and in it I have carried the exhaustion to a high point (0·1 mm). I pass the induction current, and you perceive the electrified molecules, like the line of light in the first tube, also move in straight lines, and make their path apparent by impinging on a phosphorescent screen, D E. If, however, I submit them to the action of a magnet, C, their behaviour is different. The line dips down to F, but does *not* recover itself. It seems that in the tube first shown we have to do with the average behaviour of the molecules of gas in its totality. In the second case, where the gas has been greatly attenuated, we are merely concerned with the behaviour of the individual molecules of which it was originally composed.

### *The Stratified Discharge.*

When the gas is rarer than is necessary to give the flexible line of light, as shown in the first experiment, the luminosity is plainly discontinuous or, as it is termed, stratified.

A very good illustration of this fact may be taken from the moving crowd in any such frequented street—say Fleet-street. If at some time when the stream of traffic runs almost equally in both directions, we take our stand at a window from which we can overlook the passing crowd, we shall notice that the throng on the foot-way is not uniformly distributed, but is made up of knots—we might almost say blocks—interrupted by spaces which are comparatively open. We may easily con-

* I speak of "collisions," as these are the generally accepted *substrata* of the kinetic theory. But Prof. Silvanus P. Thompson reminds me that Boltzmann some years ago proposed a modification of the kinetic theory which to me seems a vast improvement on the somewhat bald notion of molecular collisions. According to Boltzmann's view, in a so-called "collision" the molecules do not actually bounce against one another, but merely fly round in two interlocking hyperbolic paths. The effect, for all external purposes, will be the same as if they collided, because of the extreme minuteness of the curved part of the paths. The gain in thus regarding the matter is that such hyperbolic paths are quite consistent with obedience to the ordinary laws of gravitational attraction; whereas the collision theory needs for its explanation that when molecules come very near together they should exhibit a repulsion varying inversely as the fifth power of the distance between them.

* My measurements of high vacua have all been taken with the beautiful little gauge devised by Prof. McLeod. Unmerited discredit has recently been cast on this gauge, the principal fault alleged being its inability to distinguish between the tension of the permanent gas and that of the mercury vapour present. Now it is evident that, under ordinary circumstances, the tension of mercury vapour may be disregarded, as it will be the same on both sides of the gauge: and it will be only in cases where no mercury is present on one side of the gauge that a slight error is introduced. It is, however, very difficult to devise and successfully experiment with apparatus in which a trace of mercury vapour shall not enter, and it is not likely that an experimentalist who would be working with such mercury-free apparatus would attempt to use the gauge without remembering that in this special case the indications would be incorrect. To use the McLeod gauge requires much patience and some amount of experience, but I have always found it trustworthy to register exhaustions far beyond the millionth of an atmosphere. I can adduce circumstantial evidence of the accuracy of its readings at these high vacua. In the year 1881 I read a Paper before the Royal Society on "The Viscosity of Gases at High Exhaustions" (*Phil. Trans.*, 1881, p. 387), and illustrated my results in three large diagrams, on which I plotted the experimental results obtained at rarefactions up to the 0·02 millionth of an atmosphere, giving curves comparing the decrease in viscosity with that of the repulsion resulting from radiation, at the different pressures. Now these curves, in the case of air, for instance, are perfectly regular and uniform in their falling off, and it is evident that this could not have been the case unless the abscissæ representing viscosity and the ordinates representing pressure were equally accurate. I am satisfied that, within narrow limits, the abscissæ of viscosity are correct to the highest point, and the conformity of experiment to theory in the shape of these curves is a conclusive proof that, at as high an exhaustion as 0·02 M., the McLeod gauge is to be trusted to give accurate results within 2 per cent. of the truth. To give some idea what these high exhaustions mean, I may mention that the highest measured exhaustion—0·02 M.—bears the same proportion to the ordinary pressure of the atmosphere that a millimetre does to 30 miles, or, in point of time, that one second bears to 20 months.

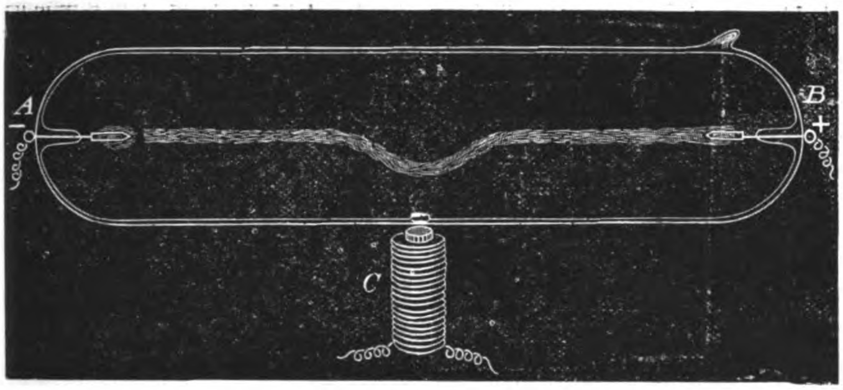

FIG. 1.—Pressure = 75 mm.

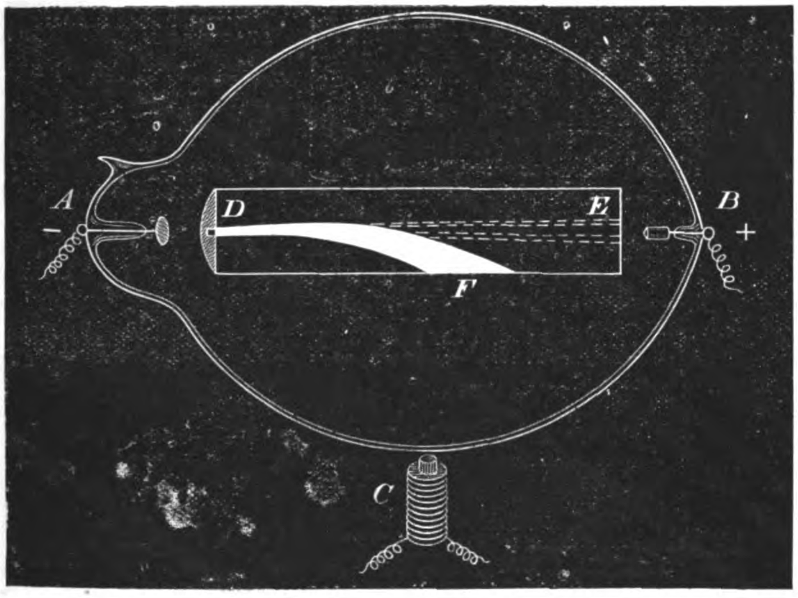

FIG. 2.—Pressure = ·1 mm. = 131·5 M.

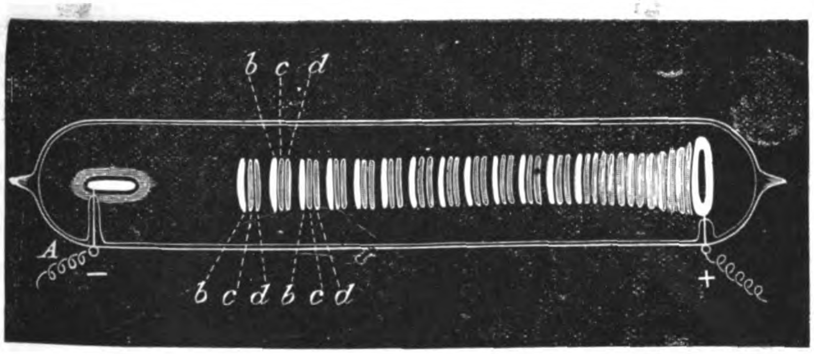

FIG. 3.—Pressure = 2 mm. = 2,630 M.

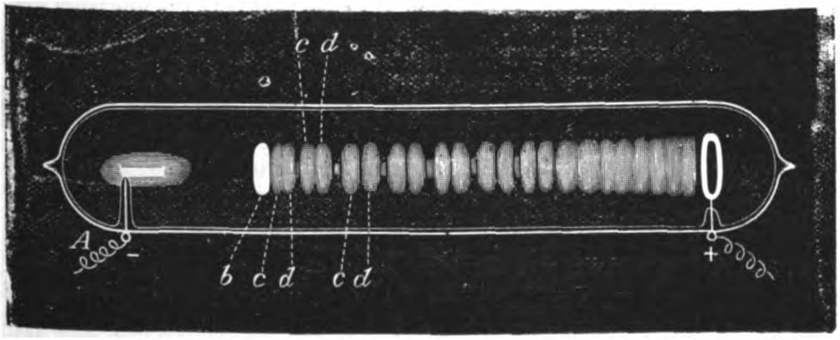

FIG. 4.—Pressure = 2mm. = 2630 M.

ceive in what manner these knots or groups are formed. Some few persons walking rather more slowly than the average rate slightly retard the movements of others whether travelling in the same or in an opposite direction. Thus a temporary obstruction is created. The passengers behind catch up to the block and increase it, and those in front, passing on unchecked at their former rate, leave a comparatively vacant space. If a crowd is moving all in the same direction the formation of these groups becomes more distinct. With vehicles in crowded streets, the result, as everyone may have remarked, will be the same.

Hence mere differences in speed suffice to resolve a multitude of passengers into alternating gaps and knots.

Instead of observing moving men and women, suppose we experiment on little particles of some substance, such as sand, approximately equal in size. If we mix the particles with water in a horizontal tube and set them in rhythmical agitation, we shall see very similar results, the powder sorting itself with regularity into alternate heaps and blank spaces.

If we pass to yet more minute substances we observe the behaviour of the molecules of a rarefied gas when submitted to an induction current. The molecules here are free, of course, from any caprice and simply follow the law I seek to illustrate, and though originally in a state of rampant disorder, yet under the influence of the electric rhythm they arrange themselves into well-defined groups or stratifications; the luminosities show where arrested motion with concomitant friction occurs, and the dark intervals indicate where the molecules travel with comparatively few collisions.

### *Party-coloured Stratifications.*

As another illustration of stratifications in a moderately-exhausted tube (P. = 2 mm.), I will take the case of hydrogen prepared from zinc and sulphuric acid after being passed through various purifying agents, dried in the usual manner, and exhausted with a mercury pump (Fig. 3). I pass the induction current, and we see that the stratifications are tricoloured, blue, pink, and grey. Next the negative pole A is a luminous layer, then comes a dark interval or Faraday's dark space (see below), and after this are the stratifications, the front component (*b*) of each group blue, the next (*c*) pink, and the third (*d*) grey. The blue discs are somewhat erratic. At a certain stage of exhaustion all the blue components of the stratifications suddenly migrate to the front, forming one bright blue disc, and leaving the pink and grey components by themselves. The tube before you (Fig. 4) is at this particular stage of exhaustion, and on passing the current you observe the blue disc only (*b*) is in front. When the tube contains a compound gaseous residue of this kind, the form of stratifications can be very considerably altered by varying the potential of the discharge. This alteration in the forms of stratification was first pointed out by Gassiot (1865, "B.A. Abstracts," p. 15), who gave very full descriptions and drawings of the alterations produced by putting in resistances of various lengths of distilled water. That the alteration depends simply upon the difference of potential the following experiment pretty clearly shows:—Here is a tube giving on my coil the coloured stratification usually attributed to

Digitized by Google

the presence of residual hydrogen, but which I find is due to a mixture of hydrogen, mercury, and hydro-carbon vapours. Now, by altering the brake so as to produce frequent discharges of lower potential, you see the stratifications gradually change in shape and become all pink; again altering the brake so as to send less rapid discharges at a much higher potential, once more we get the coloured stratifications. When in this state, if we introduce a water resistance into the circuit so as to damp down the potential, exactly the same thing happens. The blue disc is caused by mercury; its

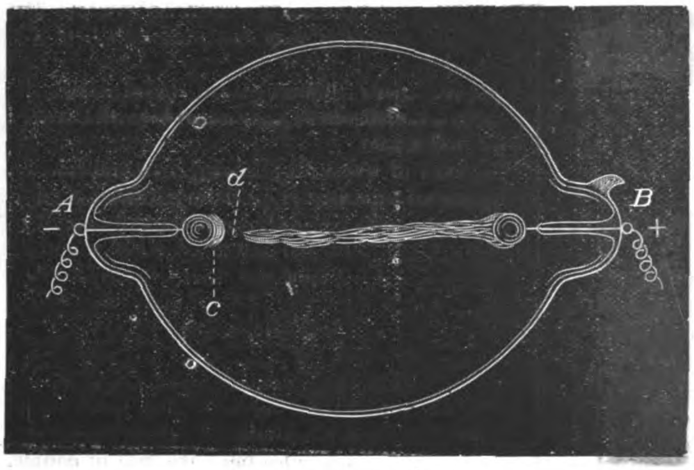

Fig. 5. - Pressure = 6mm.

spectrum is that of mercury only, without even a trace of the bright red line of hydrogen. Experiments not yet finished make it very probable that the pink discs are due to hydrogen, and that the grey discs indicate carbon. The tube you have just seen contains nothing but hydrogen, mercury, and a minute trace of carbon; but with all the resources at my command I have not been able to get hydrogen quite free from impurity. Indeed, I do not think absolutely pure hydrogen has ever yet been obtained in a vacuum tube. I have so far succeeded as to completely eliminate the mercury, and almost completely to remove the trace of carbon. On the table is such a tube giving uniformly pink stratifications, and showing no blue or grey discs with any potential of current.

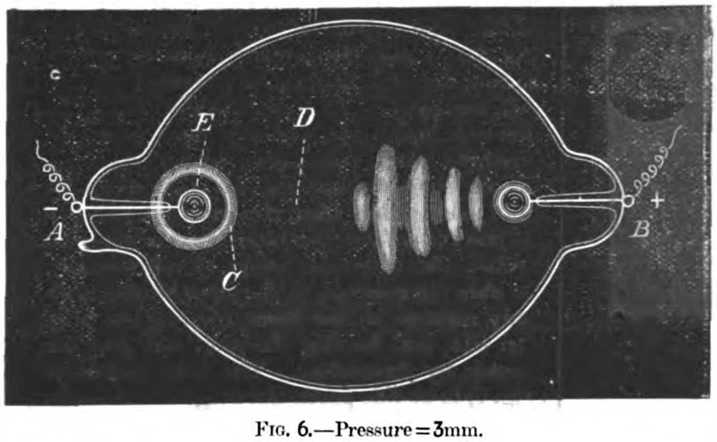

Fig. 6.—Pressure = 3mm.

*The Dark Space.*

After the stratification stage is passed, we come to a very curious phenomenon, the so-called "Dark Space." Studying electrical phenomena in gases, in the year 1838, Faraday* pointed out a break in the continuity of the luminous discharge separating the glow of the positive electrode from that of the negative. This he called "the dark space." It is seen in tubes containing gas only slightly rarefied, as in this tube (Fig. 5, P. = 6mm.), where you will observe that the positive glow, extending as a pink streak from the positive electrode, B, ends about 10 millimetres before the spot of blue light, C, representing the negative glow. This gap, or non-luminous hiatus, D, is Faraday's "dark space." Separating the negative glow from its electrode is another space. In this tube it is so small that the glow appears to be in actual contact with the electrode, but on exhausting a little further it rapidly separates; and in the next tube (Fig. 6), containing air at a little less pressure (P = 3 mm.), this dark space, E, has extended so as to remove the negative glow about four millimetres from the electrode A. It is with this second dark space that I particularly wish to deal to-night. Therefore I shall refer to it as the "dark space," meaning always that in a negative glow.

* "Experimental Researches in Electricity," 1838, par. 1,544.

In the experiment just shown with hydrogen stratifications the contents of the tube under the electric discharge still obey the laws following from the average properties of an immense number of molecules moving in every direction with velocities of all conceivable magnitudes. But if I continue exhausting, the dark space, E, round the negative pole, A, becomes visible, grows larger and larger, and at last fills up the entire tube. The molecules at this stage are in a condition different from those in a less highly exhausted tube. At low exhaustions they behave as gas in the ordinary sense of the term, but at these high exhaustions, under electric stress, they have become exalted to an *ultra-gaseous* state, in which very decided properties, hitherto masked, come into play.

The radius of the dark space varies with the degree of exhaustion, with the kind of gas in which it has been produced, with the temperature of the negative pole, and to a less extent with the intensity of the spark.

It has been erroneously assumed that I ever said the thickness of the "dark space" represents the mean free path of the molecules in their ordinary condition, and it has been pointed

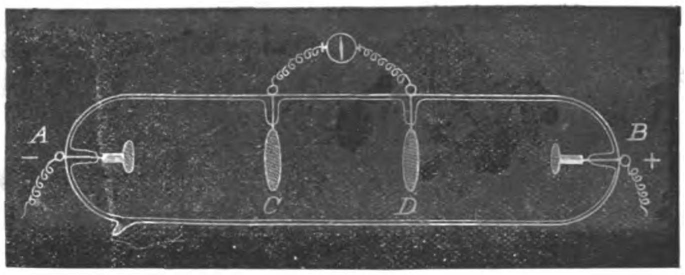

Fig. 7

out that the radius of the dark space is decidedly greater than the calculated mean free path of the molecules. I have taken accurate measurements of the radius of the dark space at different pressures, and compared it with the calculated mean free path of the gaseous molecules at corresponding pressures when not under the influence of electrical energy, and I find that they do not bear a constant relation one to the other. The length of the dark space is not twenty times the mean free path, as some have estimated, but a gradually increasing multiple must be taken as the exhaustion becomes greater.

*Exploration with Idle Poles.*

Wishing to learn something of the electrical condition of the matter within and without the dark space, I made a tube (Fig. 7), having besides the positive and negative terminals, A B, two extra intermediate poles, C and D; the tube showed that when the exhaustion was such that both the idle poles were outside the dark space, on passing the current through the tube there was a considerable difference of potential between them when measured on the galvanometer. If the exhaustion was carried so high that one of the extra poles was just on the border of the dark space, then no current passed between them. When the exhaustion was still further increased so as to enclose one of the extra poles fully in the dark space, again there was a great difference of potential between them, but the direction was reversed, the pole at highest potential now being the one formerly at lowest potential.

When the dark space has been further explored by means of a movable negative pole, I found that the effects did not depend esentially on the exhaustion, and were really due to

Digitized by Google

the position occupied by the extra poles with regard to the dark space.

These phenomena are difficult to understand from mere description, and the experiments themselves are not easy to carry out so as to be visible to many at a time. I have here, however, a working model of an apparatus which will make these puzzling indications clear to all.

A cylindrical tube (Fig. 8, *a*, *b*, and *c*, P = 0·25 mm.), furnished with the usual poles, A B at the ends, has two extra or idle poles near together at C and D. The pole A is movable along the axis of the tube, so that when exhausted the dark space can be brought to any desired position with respect to the idle poles C and D. The shading and + and − marks roughly show the distribution of positive and negative electricity inside the tube. I start with the negative pole A as far as possible from either idle pole (Fig. 8, *a*). Turning on the coil you see the dark space surrounding the pole A, and the idle poles quite outside.

The shading shows that each idle pole is in the positive area, and on testing with a gold leaf electroscope it will be seen that each is charged with positive electricity. But the shading also shows more positive at C than at D, and on connecting C and D with a galvanometer the needle indicates a rush of current from C to D, D being negative to C.

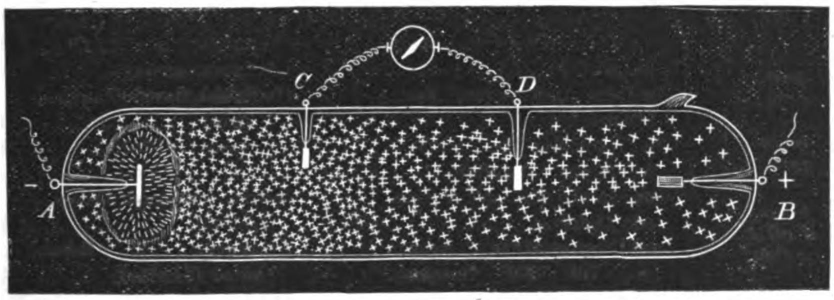

FIG. 8*a*.—·25mm. = 330 M.

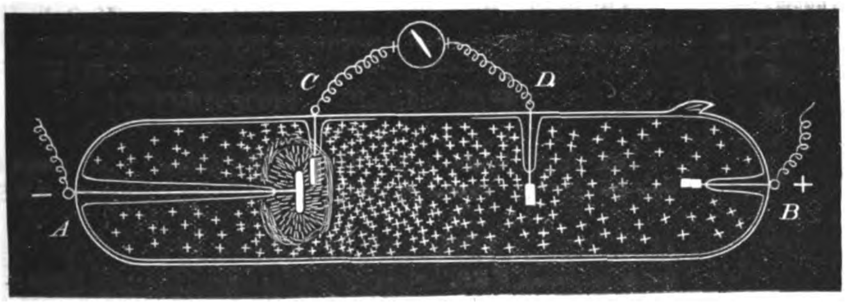

FIG. 8*b*.—·25 mm. = 330 M.

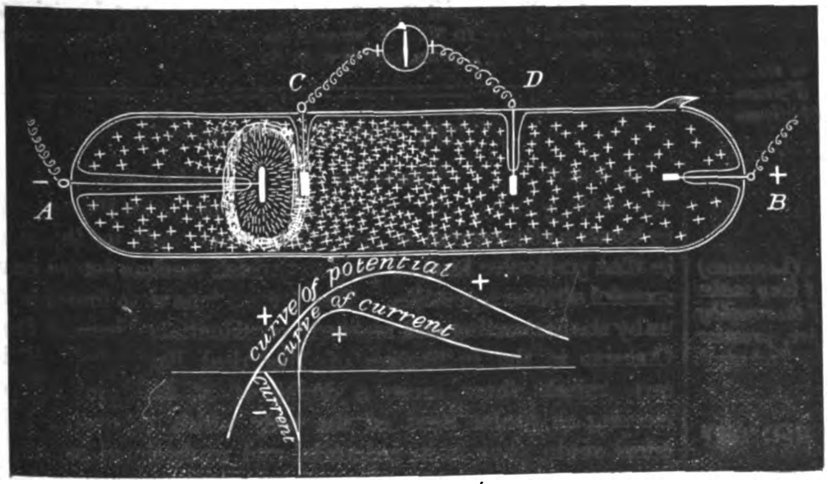

FIG. 8*c*.—P. = ·25 mm. = 330 M.

The dark space is next brought to such a position that the pole C is well within it (Fig. 8, *b*). A change has now come over the indications. The galvanometer shows a reverse current to that which was seen on the former occasion. C is now negative and D positive, but the gold leaves still tell us both poles are positively electrified.

At a certain position of the dark space, when its edge is on the pole C (Fig. 8, *c*), a neutral state is found at which the gold leaves still show strongly positive electrifications, and no current is seen on the galvanometer. The curves below (Fig. 8, *c*), roughly show the rise and fall of negative and positive current at different parts of the tube, whilst the potential curve keeps positive.

When a substance that will phosphoresce under electrical excitement is introduced into the tube, the position of greatest luminosity is found to be at the border of the dark space, just where the two opposing armies of negative and positive atoms meet in battle array and re-combine. Later on I shall refer to this phenomenon in connection with the phosphorescence of yttria.

*(To be continued.)*

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**FRIDAY, January 16th.**

PHYSICAL SOCIETY.

*5.30 p.m.* Papers to be read: "Photo Electricity," by Prof. G. W. MINCHIN, M.A.; "A Lecture Room Method of Determining 'g,'" by Prof. BARRETT, B.A.; "On the Change in the Absorption Spectrum of Cobalt Glass produced by Heat," by Sir JOHN CONROY, Bart., M.A.

INSTITUTION OF CIVIL ENGINEERS.

*7.30 p.m.* Students' Meeting. Paper to be read: "On a Survey of the Bed of Sutton Pool, Plymouth," by R. G. HANSFORD WORTH, Stud. Inst. C.E.

**TUESDAY, January 20th.**

THE INSTITUTION OF CIVIL ENGINEERS.

*8 p.m.* Ordinary Meeting. Paper to be discussed: "Auxiliary Engines in connection with the Modern Marine-Engine," by W. H. ALLEN, A.M.I.C.E.

**WEDNESDAY, January 21st.**

ROYAL METEOROLOGICAL SOCIETY.

*7 p.m.* Ordinary Meeting. Papers to be read: "Note on a peculiar development of Cirrus Cloud observed in Southern Switzerland," by ROBERT H. SCOTT, M.A., F.R.S.; "Some Remarks on Dew," by Col. W. F. BADGLEY, F.R.Met.Soc. To be followed by the Annual General Meeting of the Society at 8.15 p.m., when the Report of the Council will be read, and the Election of Officers and Council for the ensuing year will take place.

SOCIETY OF ARTS.

*8 p.m.* Ordinary Meeting. Paper to be read: "Photography in Aniline Colours," by A. G. GREEN, C. F. CROSS, and E. J. BEVAN.

ROYAL MICROSCOPICAL SOCIETY.

*8 p.m.* Annual Meeting. President's Address. Election of Council and Officers.

**THURSDAY, January 22nd.**

INSTITUTION OF ELECTRICAL ENGINEERS.

*8 p.m.* Ordinary General Meeting. Paper to be read: "The Distribution of Electricity, with especial reference to the Chelsea system," by Major-Gen. C. E. Webber, R.E.

**FRIDAY, January 23rd.**

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse: "Some Applications of Photography," by Lord RAYLEIGH, F.R.S.

Digitized by Google

# The Electrician.

**Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny**
**Editorial, Publishing, and Printing Offices:**
**SALISBURY COURT, FLEET ST., LONDON, E.C.**
*Telephone No. 2714. Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

*All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher,* "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co." *All other letters to be addressed to the Editor.*

*All letters intended for insertion in* "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

*New Volumes of* "THE ELECTRICIAN" *commence in May and November.*

## SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

| | 3 months. s. d. | 6 months. s. d. | 12 months. s. d. |
|---|---|---|---|
| For the United Kingdom | 5 0 | 10 0 | 19 6 |
| For Foreign Parts and Colonies:— Within Postal Union | 6 6 | 12 6 | 24 0 |
| Aden Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar | 7 6 | 14 6 | 28 0 |

## TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

*Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xvii.) are accepted up to 4 p.m. on Thursday.*

## TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

## "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

*Early in each year is issued* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883; and the 1890 Edition consisted of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

*The 1891 Edition is now actively preparing, and Subscription and Advertisement Orders, New Names, Corrections, &c., can be received.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

*All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of* "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

## SPECIAL NOTICE.

**With this Number of "THE ELECTRICIAN" is issued a fine Steel-Plate Portrait of Prof. WILLIAM CROOKES, F.R.S.**

### STEEL-PLATE PORTRAITS

*Of W. H. Preece, F.R.S.; Michael Faraday; Sir John Pender, K.C.M.G.; Sir William Thomson, F.R.S. (Past-President of the Institution of Electrical Engineers); C. H. B. Patey, C.B. (Late Secretary of Telegraphs, G.P.O.); Dr. John Hopkinson, F.R.S. (Past-President of the Institution of Electrical Engineers); and Dr. Oliver J. Lodge, F.R.S., have been issued as Supplements to* "THE ELECTRICIAN." *A few Copies of these admirably-executed Steel Engravings can be supplied, price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, post free, 4s. 6d.*

## IN THE VAN OF PROGRESS.

Decidedly England leads the way. If our American cousins are more pushing in business, and surpass us in the capacity to boom a commercial novelty, they must yield us the palm in that particular kind of progress which renders future commercial advances possible. These reflections were forced upon us by the interesting and masterly presidential address of Prof. CROOKES to the Institution of Electrical Engineers. If in any minds there arose a doubt as to the propriety of electing as titular head of the body which represents electrical engineering in its industrial and professional aspects a chemist of world-wide distinction, it can only have been because the reputation of Prof. CROOKES as an electrician has been outshone by his fame as a chemist. But the presidential address which, by the courtesy of the President and officials of the Institution, we are able to present to our readers, affords ample justification of the choice made by the Council of that body in their selection for the current year. Not that the new President stood in need of any such justification; for his important works of earlier date can never be forgotten by the electrical fraternity. The improvements which from 1872 to 1876 he effected in the Sprengel vacuum-pump, when studying the repulsion due to radiation in exhausted tubes, not only led him to the invention of that fascinating toy, the radiometer, but enabled him to attain much higher degrees of exhaustion than had previously been

considered practicable, and, in this way, beyond all question paved the path of progress for the production five years later of the commercially successful glow-lamp. It is hardly too much to say that but for the researches of Prof. Crookes on high vacua at the date named very little would have been heard of the subsequent inventions of Swan, Edison, Lane-Fox, and others. Again, in continuation of these researches on high vacua, Prof. Crookes became the discoverer of that peculiar state which a highly attenuated gas assumes when subjected to an electric discharge, to which its discoverer has given the name of the "radiant matter" state; when, instead of pressing equally in all directions as ordinary gases do, it acts with greatly increased pressures, directed normally to the surface of the negative electrode. It was in pursuance of this line of discovery that Prof. Crookes was led to observe the strange phosphorescent lights with which certain substances, notably the rare earthy oxide yttria, the commoner oxide alumina, its rare crystalline variety the ruby, sundry other gems, and certain kinds of glass, exhibit when subjected to the discharge of the electrified molecules in a stream of radiant matter. In submitting the rays of these strange luminosities to the analysis of the spectroscope, Prof. Crookes was led on to institute a research into the group of curiously-allied metals of the earths alumina, glucina, yttria, erbia, samaria, and their congeners; with the result that to account for the singular properties so revealed, he was compelled to frame a hypothesis that the atoms of these elements or meta-elements are not all alike, but differ slightly *inter se*. According to this view the qualities hitherto attributed to any one of these metals are only a sort of average of the qualities possessed by its atoms; a view which, if substantiated, will contravene the *obiter dictum* of Maxwell, that the atoms of each distinct element were all similar, like well-manufactured articles. Considerations respecting the cause of these minute differences between the individual atoms of which any mass of an element is composed led Prof. Crookes on into an intricate speculation as to the possible genesis of the elements out of some simpler primordial stuff, which, under the influence of periodically recurring forces of an electric nature, took upon itself many complex groupings, of which some being unstable were but temporary, whilst others were of permanent type. In this way he sought to explain those remarkable recurrences of natural properties which are found to exist when the elements are considered in the order of their various atomic weights. The discovery of this "periodic" law, first by the English chemist Newlands, and later by the Russian Mendeljeff, was a great advance in theoretical chemistry; but it was reserved to Prof. Crookes to find in it a stepping-stone to still more advanced speculations upon the origin of the elements.

To the topics of extremely attenuated vacua, radiant matter, electric phosphorescence, and the genesis of elements and meta-elements thus closely connected in the development of Prof. Crookes's past researches, he has now returned in his presidential discourse. With a master's hand he has shown how the electric spark may become to the chemist a tool of the most precious and refined capabilities in unravelling phenomena of a degree of complexity and delicacy that would deter many a less-gifted experimenter and utterly baffle one possessing only the old chemical reagents and instruments of research. He has afresh examined the relations between the nature of the luminous discharge and the pressures of the residual gases in his highly exhausted bulbs and tubes, has triumphantly swept away sundry fictions, and has unravelled several of the problems which had hitherto escaped solution.

The vexed question of the origin of the parti-coloured stratifications, seen in a vacuum tube at a certain stage of exhaustion, has now entered on a new phase. And though it will doubtless be unsatisfactory to the ordinary chemist to learn that so simple a substance as hydrogen gas has never been obtained in a state of purity, it is some compensation to know what are the causes of the ever-present impurities. Again, when so notable a discovery as that of the radiant-matter state has been called in question by a skilled German experimenter, it is most gratifying to find that Prof. Crookes has been able to dispose of the points alleged in controversy by such a cogent and convincing series of experimental demonstrations as those which he has put forth. He seems, indeed, to have revelled in piling proof upon proof to establish his original proposition as to the nature of the molecular discharge set up by the electrical forces in his phosphorescent tubes.

The audience which cheered Prof. Crookes's brilliant succession of experiments, aroused as it was to no common pitch of enthusiasm, did not spend its cheers simply upon the glowing rubies and gleams of golden phosphorescence, nor yet upon the ingenious mechanical and experimental devices adopted in the investigations. Its applause was elicited by his successful quest into depths of the unknown. That, to adopt the President's own words, seed was being scattered for future discoveries and inventions, which must in due time bear its appropriate fruit. True, the mysteries of the electric discharge and of the electrical relations of vacuous space have not all been solved; they have indeed been added to by the discovery of new and puzzling facts. Why the presence of an outer tube of silver, or other good conductor, should act as an obstruction to the passage of an electric spark in the vacuous space within it, is a puzzle only equalled by the converse phenomenon that the presence of phosphorescent substances, all of which are non-conducting in themselves, should facilitate the passage of the discharge.

One thing we should like to see done. It is impossible to read Prof. Crookes's address without observing that he couches the description of his results in the ancient language of the two-fluid theory, and speaks of "positive electricity" and "negative electricity" as though they were two different things rather than two converse manifestations of one and the same entity. We are not saying that Prof. Crookes is wrong; it is very largely a question of language, and doubtless he has chosen those terms which best conveyed what he had in his mind. Nevertheless, we cannot but think that there would be some advantage if the same facts could be simply re-stated in more modern language. The older mode of speech is admittedly the simpler for describing a few of the phenomena of electricity, particularly those of electrolysis. But Prof. Crookes has himself shown us that the analogy between the gaseous conveyance of electricity and its conduction through an electrolytic liquid is less close than had previously been supposed. There is, therefore, all the less reason for following the language applied to electrolytic phenomena.

Prof. Crookes's presidential address, though it announces no new invention and propounds no new or startling theory, will, nevertheless, stand out in striking relief as a remarkable contribution to science; it will stamp the year 1891, even at this early date, as a year of progress in pure research. He has pushed investigation into the borderland between the known and the unknown one stage further, and this in a department of science where progress is only possible to one possessing the peculiar double qualification of electrician and chemist.

Digitized by Google

It is an honour to the Institution that such an address should emanate from its President, and we venture to predict that it will prove to be as fertile in stimulating research and invention as any of the presidential addresses of previous years have proved; for, in the eloquent words of the address, "pure research is the abundant source from which spring endless streams of practical application."

## ELECTRO-MAGNETIC THEORY.—II.

BY OLIVER HEAVISIDE.

(*Continued from p. 258.*)

§ 8. There are men of a certain type of mind who are never wearied with gibing at mathematics, at mathematicians, and at mathematical methods of inquiry. It goes almost without saying that these men have themselves little mathematical bent. I believe this to be a general fact; but, as a fact, it does not explain very well their attitude towards mathematicians. The reason seems to lie deeper. How does it come about, for instance, that whilst they are themselves so transparently ignorant of the real nature, meaning, and effects of mathematical investigation, they yet lay down the law in the most confident and self-satisfied manner, telling the mathematician what the nature of his work is (or rather is not), and of its erroneousness and inutility, and so forth? It is quite as if they knew all about it.

It reminds one of the professional paradoxers, the men who want to make you believe that the ratio of the circumference to the diameter of a circle is 3, or 3·125, or some other nice easy number (any but the right one); or that the earth is flat, or that the sun is a lump of ice; or that the distance of the moon is exactly 6 miles 500 yards, or that the speed of the current varies as the square of the length of the line. They, too, write as if they knew all about it! Plainly, then, the anti-mathematician must belong to the same class as the paradoxer, whose characteristic is to be wise in his ignorance, whereas the really wise man is ignorant in his wisdom. But this matter may be left for students of mind to settle. What is of greater importance is that the anti mathematicians sometimes do a deal of mischief. For there are many of a neutral frame of mind, little acquainted themselves with mathematical methods, who are sufficiently impressible to be easily taken in by the gibers and to be prejudiced thereby; and, should they possess some mathematical bent, they may be hindered by their prejudice from giving it fair development. We cannot all be Newtons or Laplaces, but that there is an immense amount of moderate mathematical talent lying latent in the average man I regard as a fact; and even the moderate development implied in a working knowledge of simple algebraical equations can, with common sense to assist, be not only the means of valuable mental discipline, but even be of commercial importance (which goes a long way with some people), should one's occupation be a branch of engineering for example.

§ 9. "Mathematics is gibberish." Little need be said about this statement. It is only worthy of the utterly illiterate.

"What is the use of it? It is all waste of time. Better be doing something useful. Why, you might be inventing a new dynamo in the time you waste over all that stuff." Now, similar remarks to these I have often heard from fairly intelligent and educated people. *They* don't see the use of it, that is plain. That is nothing; what is to the point is that they conclude that it is of no use. For it may be easily observed that the parrot-cry "What's the use of it?" does not emanate in a humble spirit of inquiry, but on the contrary, quite the reverse. You can see the nose turn up.

But what is the use of it, then? Well, it is quite certain that if a person has no mathematical talent whatever he had really better be doing something "useful," that is to say, something else than mathematics, (inventing a dynamo, for instance,) and not be wasting his time in (so to speak) trying to force a crop of wheat on the sands of the sea-shore. This is quite a personal question. Every mind should receive fair development (in good directions) for what it is capable of doing fairly well. People who do not cultivate their minds have no conception of what they lose. They become mere eating and drinking and money-grabbing machines. And yet they seem happy! There is some merciful dispensation at work, no doubt.

"Mathematics is a mere machine. You can't get anything out of it that you don't put in first. You put it in, and then just grind it out again. You can't discover anything by mathematics, or invent anything. You can't get more than a pint out of a pint pot." And so forth.

It is scarcely credible to the initiated that such statements could be made by any person who could be said to have an intellect. But I have heard similar remarks from really talented men, who might have fair mathematical aptitude themselves, though quite undeveloped. The fact is, the statements contain at once a profound truth, and a mischievous fallacy. That the fallacy is not self evident affords an excuse for its not being perceived even by those who may (perhaps imperfectly) recognise the element of truth. But as regards the truth mentioned, I doubt whether the caviller has generally any distinct idea of it either, or he would not express it so contemptuously along with the fallacy.

§ 10. By any process of reasoning whatever (not fancy) you cannot get any results that are not implicitly contained in the material with which you work, the fundamental data and their connections, which form the basis of your inquiry. You may make mistakes, and so arrive at erroneous results from the most correct data. Or the data may be faulty, and lead to erroneous conclusions by the most correct reasoning. And in general, if the data be imperfect, or be only true within certain limits hardly definable, the results can have but a limited application. Now all this obtains exactly in mathematical reasoning. It is in no way exempt from the perils of reasoning in general. But why the mathematical reasoning should be singled out for condemnation as mere machine work, dependent upon what the machine is made to do, with a given supply of material, is not very evident. The cause lies deep in the nature of the anti-mathematician; he has not recognised that all reasoning must be, in a sense, mechanical, else it is not sound reasoning at all, but vitiated by fancy.

Mathematical reasoning, is fundamentally, not different from reasoning in general. And as by the exercise of the reason discoveries can be made, why not by mathematical reasoning? Whatever were Newton and the long array of mathematical materialists who followed him doing all the time? Making discoveries, of course, largely assisted by their mathematics. I say nothing of the pure mathematicians. Their discoveries are extensions of the field of mathematics itself—a perfectly limitless field. I refer only to students of Nature on its material side, who have employed mathematics expressly for the purpose of making discoveries. Some of the unmathematical believe that the mathematician is merely engaged in counting or in doing long sums; this probably arises from reminiscences of their schooldays, when they were flogged over fractions. Now this is only a part of his work, a sometimes necessary and very disagreeable part, which he would willingly hand over to a properly trained computator. This part of the work only concerns the size of the effects, but it is the effects themselves to which I refer when I speak of discoveries.

§ 11. Mathematics is reasoning about quantities. Even if qualities are in question, it is their quantities that are subjected to the mathematics. If there be something which cannot be reduced to a quantity, or more generally to a definite function, no matter how complex and involved, of any number of other quantities which can be measured (either actually, or in imagination), then that something cannot be accurately reasoned about, because it is in part unknown. Not unknown in the sense in which a quantity is said to be unknown in algebra, when it is virtually known because virtually expressible in terms of known quantities, but literally unknown by the absence of sufficient quantitative connection with the known. Thus only the known can be accurately reasoned about. But this includes, it will be observed, everything that can be deduced from the known, without appeal to the unknown. The unknown is not necessarily unknowable; fresh knowns may make the former unknowns become also known. The distinction is

Digitized by Google

a very important one. The limits of human knowledge are ever shifting. But there must be an ultimate limit, because we are a part of Nature, and cannot go beyond it. Beyond this limit, the Unknown becomes the Unknowable, which it is of little service to discuss, though it will always be a favourite subject of speculation. But whatever is in this Universe can be (or might be) found out, and therefore does not belong to the unknowable. Thus the constitution of the middle of the sun, or of the ether, or the ultimate nature of magnetisation, or of universal gravitation, or of life, are not unknowable, and this statement is true, even though they should never be discovered. There are no inscrutables in Nature. By Faith only can we go beyond—as far and where we please.

Human nature, or say a man, is a highly complex quantity. We are compelled to take him in parts, and consider this or that quality, and imagine it measured and brought into proper connection with other qualities and external influences. Yet a man, if we only knew him intimately enough, could be formularised, and have his whole life-history developed. Even the universe itself, if every law in action were thoroughly known, could have its history, past, present, and to come, formularised down to the minutest particulars, provided no discontinuity or special act of creation occur. But even the special act of creation could be formularised, and its effects deduced, if we knew in what it consisted. And special acts of creation might be going on continuously, involving continuous changes in the laws of nature, and could be formularised, if the acts of creation were known, or the—so to speak—law of the discontinuities. The case is somewhat analogous to that of impressed forces acting upon a dynamical system. The behaviour of the system is perfectly definite and formularisable so long as no impressed forces act, and ceases to be definite if unknown impressed forces act. But if the forces be also known, then the course of events is again definitely formularisable. The assumption of a special act of creation, either now or at any time, is merely a confession of ignorance. We have no evidence of any such discontinuities. We cannot prove that there have never been any; nor can we prove that the sun will not rise to-morrow, or that the clock will not wind itself up again when the weight has run down.

§ 12. Nearly all the millions, or rather billions, of human beings who have peopled this earth have been content to go through life taking things as they found them, and without any desire to understand what is going on around them. It is exceedingly remarkable that the scientific spirit (asking how it is done), which is so active and widespread at the present day, should be of such recent origin. With a few exceptions, it hardly existed amongst the Ancients (who would be more appropriately termed the Youngsters). It is a very encouraging fact for evolutionists, leading them to believe that the evolution of man is not played out; but that man is capable, intellectually, of great development, and that the general standard will be far higher in the future than at present.

Now, in the development of our knowledge of the workings of Nature out of the tremendously complex assemblage of phenomena presented to the scientific inquirer, mathematics plays in some respects a very limited, in others a very important part. As regards the limitations, it is merely necessary to refer to the sciences connected with living matter, and to the ologies generally, to see that the facts and their connections are too indistinctly known to render mathematical analysis practicable, to say nothing of the complexity. Facts are of not much use, considered as facts. They bewilder by their number and their apparent incoherency. Let them be digested into theory, however, and brought into mutual harmony, and it is another matter. Theory is the essence of facts. Without theory scientific knowledge would be only worthy of the madhouse.

In some branches of knowledge, the facts have been so far refined into theory that mathematical reasoning becomes applicable on a most extensive scale. One of these branches is Electro-magnetism, that most extensive science which presents such a remarkable twosidedness, showing the electric and the magnetic aspects either separately or together, in stationary conditions, and a third condition when the electric and magnetic forces act suitably in dynamical combination, with equal development of the electric and magnetic energies, the state of electro magnetic waves.

It goes without saying that there are numerous phenomena connected with electricity and magnetism which are very imperfectly understood, and which have not been formularised, except perhaps in an empirical manner. Such is particularly the case where the sciences of Electricity and Chemistry meet. Chemistry is, so far, eminently unmathematical (and therefore a suitable study for men of large capacity, who may be nearly destitute of mathematical talent—but this by the way), and it appears to communicate a part of its complexity and vagueness to electrical science whenever electrical phenomena which we can study are accompanied by chemical changes. But generally speaking, excepting electrolytic phenomena and other complications, (*e.g.*, the transport of matter in rarefied media when electrical discharges occur) the phenomena of electro-magnetism are, in the main, remarkably well-known, and amenable to mathematical treatment.

§ 13. Ohm (a distinguished mathematician, be it noted) brought into order a host of puzzling facts connecting electromotive force and electric current in conductors, which all previous electricians had only succeeded in loosely binding together qualitatively under some rather vague statements. Even as late as 20 years ago, "quantity" and "tension" were much used by men who did not fully appreciate Ohm's law. (Is it not rather remarkable that some of Germany's best men of genius should have been, perhaps, unfairly treated? Ohm; Mayer; Reis; even von Helmholtz has mentioned the difficulty he had in getting recognised. But perhaps it is the same all the world over.) Ohm found that the results could be summed up in such a simple law that he who runs may read it, and a schoolboy now can predict what a Faraday then could only guess at roughly. By Ohm's discovery a large part of the domain of electricity became annexed to theory. Another large part became virtually annexed by Coulomb's discovery of the law of inverse squares, and completely annexed by Green's investigations. Poisson attacked the difficult problem of induced magnetisation, and his results, though differently expressed, are still the theory, as a most important first approximation. Ampère brought a multitude of phenomena into theory by his investigations of the mechanical forces between conductors supporting currents and magnets. Then there were the remarkable researches of Faraday, the prince of experimentalists, on electrostatics and electrodynamics and the induction of currents. These were rather long in being brought from the crude experimental state to a compact system, expressing the real essence. Unfortunately, in my opinion, Faraday was not a mathematician. It can scarcely be doubted that if he had been one, he would have been greatly assisted in his researches, have saved himself much useless speculation, and would have anticipated much later work. He would, for instance, knowing Ampère's theory, by his own results have readily been led to Neumann's theory, and the connected work of Helmholtz and Thomson. But it is perhaps too much to expect a man to be both the prince of experimentalists and a competent mathematician.

Passing over the other developments which were made in the theory of electricity and magnetism, without striking new departures, we come to about 1860. There was then a collection of detached theories, but loosely connected, and embedded in a heap of unnecessary hypotheses, scientifically valueless, and entirely opposed to the spirit of Faraday's ways of thinking, and, in fact, to the spirit of the time. All the useless hypotheses had to be discarded, for one thing; a complete and harmonious theory had to be made up out of the useful remainder, for another; and, in particular, the physics of the subject required to be rationalised, the supposed mutual attractions or repulsions of electricity, or of magnetism, or of elements of electric currents upon one another, abolished, and electromagnetic effects accounted for by continuous actions through a medium, propagated in time. All this, and much more, was done. The crowning achievement was reserved for the heaven-sent Maxwell, a man whose fame, great as it is now, has, comparatively speaking, yet to come.

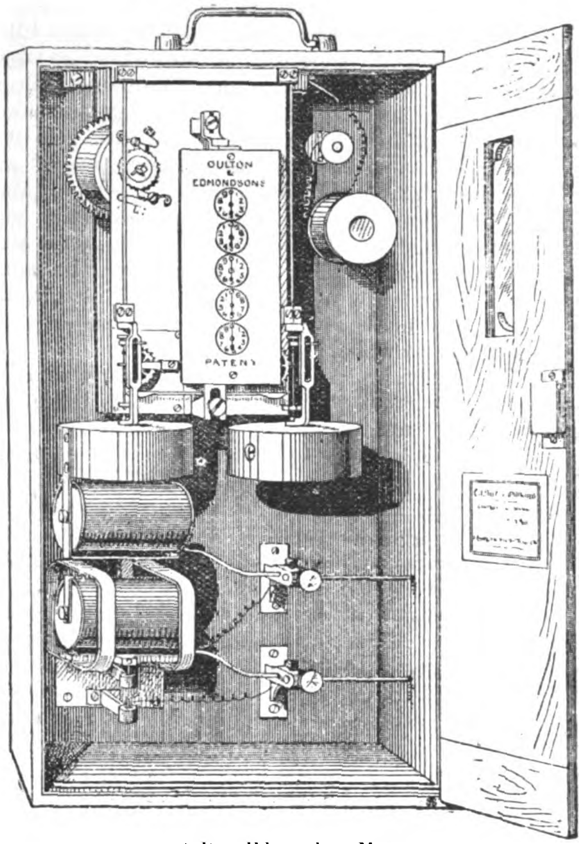
## THE OULTON-EDMONDSON METER.

This meter in its original form was fully described in *The Electrician*, Vol. XXIV., p. 111. The instrument has since then been subjected to prolonged tests, and has been modified in several respects. It now measures watts and is arranged for alternating or for continuous currents.

The meter consists of a clock train having two "torsion balances" which keep identical time, except when current is being consumed. When a current passes through the main conductor it quickens the speed of one of the balances, and the difference of speed (registered on the dials in B.T. units) is a measure of the current consumed. A difference of 10 beats per hour = 1 B.T. unit, and the measurement is proportional to the current throughout the whole range for which each instrument is constructed. Both balances are driven by one mainspring, the force of which is equally divided betwen them by a novel "differential gear."



Oulton-Edmondson Meter.

The electrical arrangements consist of two "compound-wound" solenoids, astatically attached to one of the balances, and swinging, the one *above* and the other *within*, the coils of the main conductor, and influenced by the current to be measured. The principal winding of the swinging solenoids consists of fine wire, connected with a fixed resistance coil (by which the instrument is calibrated), and coupled across the supply terminals. In a 100 ampere meter these high resistance or volt coils consume about ·007 ampere on a circuit of 100 volts. By themselves, however, they would not give proportional readings. For in pendulums and chronometric balances the force required to produce the vibrations is proportional to the square of the number of vibrations in a given time. If, therefore, $a$ = the normal number of vibrations, and $b$ = the number to be added by the current, the force required to produce $a$ will be $a^2$, and to produce $a + b$ will be $a^2 + 2\,a\,b + b^2$; the difference $(2\,a\,b + b^2)$ being the force to be exerted by the current under measurement. With the volt coils alone, the force actually exerted would be in the ratio $2\,a\,b + b$ only. Upon each volt coil, therefore, there is wound a "correcting coil," carrying a very small proportion of the current passing into consumption. If correctly calibrated, this small current brings the ratio up to $2\,a\,b + b^2$.

The right hand balance (*see* Figure) weighs about 4lb. It contains two "timing screws," which are really small weights, which, when screwed inwards will *quicken*, and when outwards will *retard*, the vibrations of the balance. The number of vibrations is about 15 per minute. The balance spring, instead of being coiled as in a watch, is quite straight, and forms the means of suspending the balance, which thus vibrates practically without friction. This spring acts by "torsion," a principle familiar to all who have seen the "400 day clock." The left hand balance and its solenoids are of about the same weight as the above, so as to vibrate in the same period of time.

Although driven by the same mainspring the two balances are free to move independently. The current for the volt and correcting coils is conveyed from the positive terminal to a mercury cup placed concentrically with the left hand balance, into which a wire upon, and concentric with, the balance projects. After traversing the volt coils it is conveyed up the "torsion spring" and through the fixed resistance coil to a terminal over the top of the case, and thence to the negative main. The current traversing the correcting coils returns through the upper mercury cup to the negative terminal of the instrument. This current is very small, as, for one ampere on 100 volt circuit, it has to furnish a magnetic force equal to only $\frac{1}{1800}$ of that furnished by the volt coils. As, however, the turns in the correcting coils are much fewer than those in the volt coils, the actual current in the former may be (for one ampere) somewhat greater than in the latter, and it increases in proportion to the current consumed. The denominator of the fraction $\frac{1}{1800}$ is the $2\,a\,b$ of the difference $2\,a\,b + b^2$ mentioned above, when the balances nominally vibrate 900 per hour.

## THE NEW ELIHU THOMSON ELECTRIC METER.

At the meeting of the Société Internationale des Electriciens on Thursday last week, M. Abdank Abakanowicz described a meter for use with alternating or continuous currents, which has been sent by Prof. Elihu Thomson to compete for the Paris Municipal prize. The remarkable simplicity of this meter, says our Paris correspondent, attracted unusual attention. The

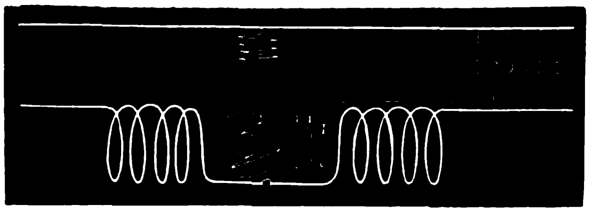


FIG. 1.—Diagram of Connections of the Elihu Thomson Meter.

instrument belongs to the group of continuously integrating motor meters, and consists essentially of a small electric motor, without iron and of a magnetic brake. The inducing coils are compound, and are wound on two rectangular frames. The thick wire is traversed by the total current. The fine wire, which is connected in series with the drum armature, and an additional non-inductive resistance, of 1,000 ohms, is arranged in shunt across the house terminals in the manner shown in the diagrammatic sketch (Fig. 1). The compounding serves to produce a couple equal to that caused by friction. The main couple tending to turn the armature is equal to E × C, that is to say, to the number of watts being consumed at any instant in the house circuit. The opposing couple is produced by Foucault currents developed in a copper disc, mounted on the same vertical axis as the armature. These currents are produced by three permanent horseshoe magnets arranged as shown in Fig 2.

The speed of rotation is very small, and is at maximum load, only one turn per second. The regulation of the apparatus is a very simple affair, since it is only necessary to have a constant difference of potential at the terminals of the shunt circuit to cause a constant current to go through the inducing coils, and to move one of the three permanent magnets until

Digitized by Google

the indications on the dials agree with the power consumed. The maximum power absorbed by the meter is 7·5 watts in the case of an instrument intended for a 50 volt 50 ampere circuit. The thin wire circuit absorbs 2·5 watts, and the thick wire circuit 5 watts. The instrument is said to register as soon as the power expended in the lamp circuit reaches 10 watts, and its inventor guarantees accuracy to within ½ per cent.

In the discussion which arose after the description of the meter, M. Sciama pointed out that the accuracy of its indications was likely to diminish in process of time since the constancy of the opposing couple depended on the permanency of the horseshoe magnets. He had noticed a diminution of 30 per cent. in one year in the strength of some permanent magnets attached to measuring instruments. On the other hand, M. R. V. Picou stated that makers had succeeded in securing such a degree of permanency with steel magnets that in three years their strength decreased by only 1 per cent. In support of this statement he instanced a Weston voltmeter brought

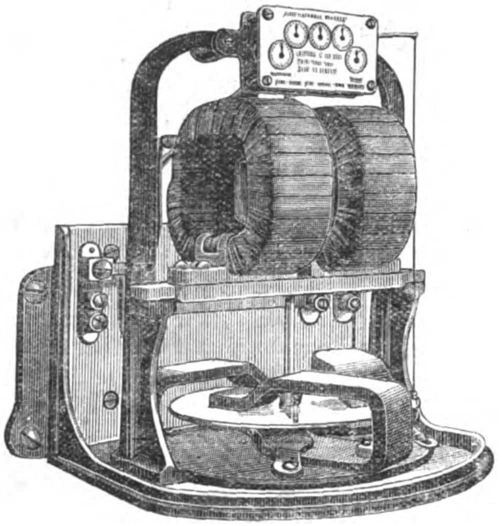

FIG. 2.—Elihu Thomson Motor Meter.

over three years ago from America by M. Abdank-Abakanowicz, and which still gave exactly the same indications. M. Picou did not know what process Weston employed to secure this remarkable permanency, but he himself obtained excellent results by the following *modus operandi*. Keep a magnetised steel bar at a temperature of 100° C. for several days. On cooling the bar will be found to have lost some of its magnetism. It must then be magnetised, and again heated to 100° C. Again its magnetism is diminished, but not to such an extent as before. It may then be magnetised a third time, and its magnetism will in reality be permanent. M. E. Sartiaux also testfied to the efficacy of this method of magnetisation.

A meter fulfilling the conditions of sensitiveness and accuracy to such a high degree as the above is certainly a remarkable one, but until the tests undertaken by the expert committee appointed by the Paris Municipal Council have been carried out, it is impossible to verify the claims put forward.

## NOTES ON THE ECONOMY OF ELECTRIC LIGHTING.

A practical paper on the cost of electric lighting compared with other illuminants is contributed to the *Electrical World* of New York by Dr. Louis Bell. As prices in the United States differ so much from those in this country, the paper as it stands would not be of direct interest to our readers. We, therefore, translate dollars and cents into shillings and pence, and interpolate where necessary comparisons with English experience, and thus contrast the economy of electric lighting in the two countries.

A few years ago, says Dr. Bell, there were very grave doubts in the minds of the majority of people concerning the possibility of really economical lighting by electricity; it was even said that while the quality and quantity of electric light would leave little to be desired, it could not be produced at a price to compete on favourable terms with gas. At this time such a statement would be immediately recognised as fallacious, for there are very many places where electric energy is sold at a price that puts gas quite in the background as an economical illuminant. A 16 candle-power electric incandescent light is the equivalent of a five-foot gas jet consuming the average quality of gas. In other words, we can in making a comparison between these two artificial lights reckon 200 electric lamp hours as the equivalent of 1,000 feet of gas. Consequently at the prevailing central station rate in America of one cent per lamp hour electric lighting costs an amount equivalent to 8s. 4d. a thousand feet for gas, while it possesses the great advantage of giving out relatively little heat and burning no oxygen out of the air. At the generally prevailing price for gas the two illuminants in the United States are so nearly on an equal footing that small accidents of situation are enough to control the question of relative economy.

The prevailing cost of electric energy in England may be put at 7¼d. per Board of Trade unit, since this is the average of the larger London companies, and the low prices in the North may be set against the few companies who charge 8d. One halfpenny per lamp hour, or one cent, as it stands in the original, for a 64 watt lamp, is equivalent to a Board of Trade unit at 7¾d. In this country, of course, there is no such equality of prices as that pointed out by Dr. Bell, since 200 lamp hours, at 64 watts per lamp, come to 12·8 units, and cost 7s. 8¾d., while gas costs from 2s. to 3s. This great discrepancy is alone sufficient to account to no small extent for the progress of electric lighting in the United States, and may be explained by the high price of gas coal as compared with steam coal in that country.

But it is not my purpose, continues Dr. Louis Bell, to discuss the somewhat worn question of electricity *versus* gas, but to call attention to what can be done in the way of domestic lighting by electricity, even when it has to compete with paraffin lamps. It may appear somewhat absurd to take the position that paraffin oil may in many cases cost as much as, or more than, electric lighting at the usual rates; nevertheless such is the fact. Of course where one is content with a comparatively small amount of light not at all equivalent to what would be secured by electricity or gas, the oil lamp owns no competitor, but if the problem in hand is to light a residence in a thoroughly satisfactory manner the conditions are very much changed. The author takes a concrete case drawn from his own observation, by way of illustration. The field of operations was a 10-room modern house in a suburban town, occupied by half-a-dozen adults. The lighting throughout was by oil lamps, 13 being in regular use, part of them having duplex burners, the others the simple flat wick. During a period covering the latter part of November and the first half of December 52 gallons of oil were consumed in 24 days. The price of oil being 6½d. per gallon, the daily cost of illumination was a small fraction over 1s. 2d. It may be added that the oil barrel had a locked faucet, so that unwarranted use of oil was prevented. While the price per gallon above given is about the same as the wholesale market price of common refined petroleum in this country, good oil free from smell costs about 10d· per gallon retail, in the small quantities generally purchased for domestic consumption. To render the comparison with electric lighting more easy, Dr. Bell reduces this figure to monthly consumption, and obtains £1. 15s. as the monthly lighting bill. Not all of the 13 lamps were lighted on every night, but they may be counted as being in regular use. This number of lamps appears to us to be high for so small a household, but the comparison is not affected thereby.

Now, what could be done under similar conditions with the incandescent lamp? On a liberal estimate, wiring the house for 15 lights would have given an illumination at least equivalent to that obtained by oil. It then appears that incandescent lamps at 2s. 8d. each per month, or £2 altogether, would have cost only one-third more than oil, with the additional great advantages of no care, no danger of fire, and no pollution of the air.

Digitized by Google

It may be replied, however, that the month taken as the basis of estimate was probably the one requiring most light, so that there would be a saving in oil during other parts of the year so great as to render the fixed charge for electricity anything but economical. This, of course, is in a measure true, but the number of incandescent lamps was deliberately taken larger than was necessary, to allow of fixed lamps in places where oil lamps are occasionally carried; and, further, 2s. 8d. per month is not a specially low rate for incandescent lamps in domestic service. In selling by contract the prices, of course, vary enormously from place to place. A few figures may, however, be of interest, particularly as they relate to small plants such as might be found in towns of very moderate size. In one small city in the United States the charge for domestic lighting is 2s. 6d. per lamp per month, the number of lights connected being less than a thousand, on the direct current system, coal being the fuel used at the station. Another direct current plant, having only 500 lights and burning coal obtained at a low rate on account of favourable situation, charges only 10d. per month for domestic service, provided at least six lights are wired. Still another, situated in a location where coal is about as expensive as in New York City, and furnishing 700 lights, charges for regular use 3s. 4d. per month, and for occasional lamps 2s. 1d. per month. As the latter class includes all lamps in sleeping apartments, and other rooms not constantly inhabited, the average price would fall to something like 2s. 6d. per month. In contract price, however, low-water mark is probably touched in a certain water-power plant where the charges for lamps in regular use average 1s. 3d. a month, and for those in occasional use, such as mentioned above, are furnished at 6¼d. per month.

It is difficult for purposes of comparison with English prices to express this 1s. 3d. per lamp-month in price per Board of Trade unit, as it is uncertain whether the lamps are turned off when not in use, and for how many hours they ought to be charged. However, taking it roughly at 100 hours per month throughout the year, and 64 watts per lamp, this would come to only a little over 2¼d. per unit, so that to make this tariff comparable with the *meter* charge of one cent per lamp hour referred to in the second paragraph, it must be supposed that the average number of lamps alight is never more than one-third of the total number wired.

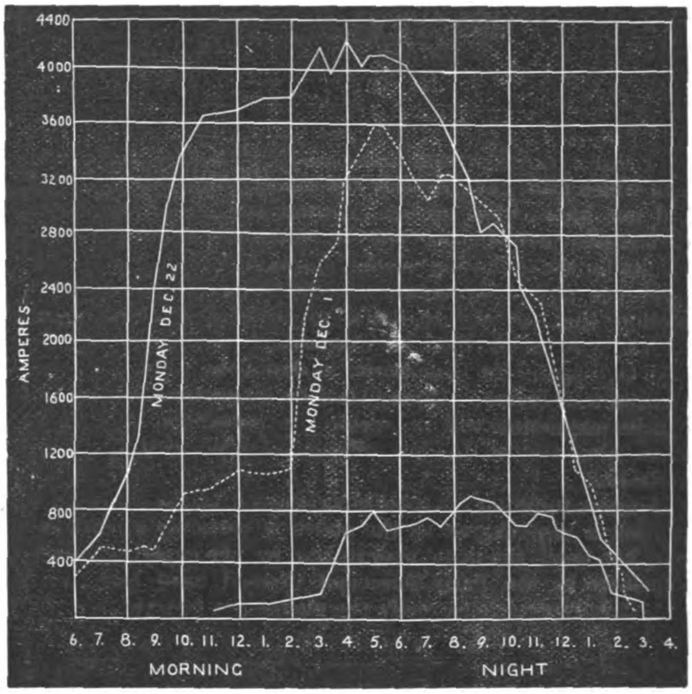
Where any considerable number of lamps, continues Dr. Bell, are used, as in large suburban towns, they can be furnished at a good profit at 2s. 1d. a month for domestic service; this, however, does not apply to commercial lighting or other cases where lamps are to be used regularly. But for the service we are discussing the price is such as very many companies would be only too glad to get. So much for lights supplied by contract. It is tolerably evident from what has been previously said that the difference in cost between oil and electricity for equal service in the United States is not very great, and may not infrequently be in favour of electricity.

Where incandescent lamps are supplied by meter the case is even more favourable. Assuming the standard central station charge of one cent per lamp hour the house above mentioned could unquestionably have been lighted as cheaply by electricity as by oil, for 32 lamp hours per night would be quite adequate for the service required; and here the comparison would be a fair one throughout the year, as only the electricity used is paid for. Unless in unfavourable situations one cent per lamp hour is a profitable selling price for incandescent lights, and this fact is attested by its being the charge made very frequently by City central stations, and even by small companies doing precisely the kind of work of which we are speaking. As a final contribution to the economy of this particular case, we are considering it should be mentioned that the price for gas in the town spoken of was 11s. 10½d. per thousand feet, which makes it distinctly more expensive than electric lighting at the rate last named. It is far from my purpose to contend that everywhere and under all circumstances electricity is the cheapest illuminant, but in many cases it could replace not only gas but oil lamps without increasing, and even in some places diminishing, the cost of illumination. Of course the weak point of the oil lamp, so far as economy is concerned, is the necessity for keeping it burning when the electric light, or even gas, would be extinguished. A lamp is not lighted without inconvenience, and therefore in rooms which will be occasionally visited during an evening oil is being constantly consumed where gas jets or incandescent lamps would be turned off. If one wished to go to the trouble of extinguishing and relighting these lamps a considerable saving might be effected; but for residences where plenty of light is desired and convenience somewhat consulted, the consumption of oil rises to an amount that gives gas and electricity an excellent chance for competition.

To sum up, where incandescent lamps can be obtained at one cent per lamp hour, or an equivalent contract price, they will compete in the United States on favourable terms not only with gas, but with oil, supposing equal illumination in each case. Aside from this the greater cleanliness and convenience of the incandescent lamp should commend it even where it is slightly at a disadvantage. It is a great pity that more suburban towns do not take advantage of electricity for house-to-house lighting, particularly since at the prices mentioned an electric light plant is in most situations a very good investment. This statement should not be understood as applying to localities where coal is very high, or where from an isolated situation or local circumstances the cost of operation rises to an amount considerably above the general average.

## LOAD DIAGRAMS OF THE ST. JAMES'S AND PALL MALL COMPANY.

The accompanying diagrams show a normal load curve (December 1, 1890) and one during a heavy fog (December 22, 1890). We are informed that this is probably the largest load curve that has been seen so far in England, if not in the world,



for a single supply station, and the efficiency of supply, owing to the machines working in parallel without any form of transformation, makes it all the more remarkable. The equivalent of 13,354 sixteen candle-power lamps are connected. We have reckoned the revenue earned on these two days, as this is a matter not without interest.

The load factor for the day of the normal curve is ·444, that is, the output was ·444 of that which would have been delivered if the maximum load had been carried for the whole 20 hours. The load factor for the foggy day is ·67. To show the increase in the normal supply made during the year we reproduce a load curve published in *The Electrician*, Vol. XXIV., p. 228, when about 2,000 lamps were connected.

## ON THE MEASUREMENT OF ELECTRO-MAGNETIC RADIATION.*

BY C. V. BOYS, F.R.S., A. E. BRISCOE, AND W. WATSON, B.SC.

*(Concluded from page 305.)*

### SECOND METHOD.

As the first method, carried out with all the delicacy which under the conditions we could make use of, gave no promise, we determined to find by some direct process whether the heat which Mr. Gregory had inferred from the expansion of the wire was real. For this purpose we made use of one of the most delicate heat-measuring instruments that exist, which is specially suitable for detecting very small quantities of heat diffused over a great length of wire, namely, the convection air-thermometer of the late Dr. Joule.† With this instrument he was able to detect the direct heating effect of the moon's rays unconcentrated by lens or mirror. His instrument consisted of a tube about 2ft. long and 4in. in diameter, divided longitudinally by a blackened pasteboard diaphragm, leaving spaces at the top and bottom. In the top space a piece of magnetised sewing-needle, furnished with a glass index, was suspended by a single silk fibre. Any excess of temperature on one side of the partition caused an air-current, which at the top passed from the hot to the cold side and deflected the needle.

We have made use of Joule's instrument, not exactly in the original form, but with two classes of index, and with an essential improvement which makes it extraordinarily sensitive without greatly affecting its simplicity. The first class of index depends for its working on the fact that when a small piece of phosphorous is placed in air it gradually oxidises, and the oxide formed slowly falls, if the air is still, in a well-defined column, appearing like smoke. If there is any very small motion of the surrounding air, this column of phosphorus oxide will be deflected. It thus forms an excessively delicate and light index for detecting movements in the air.

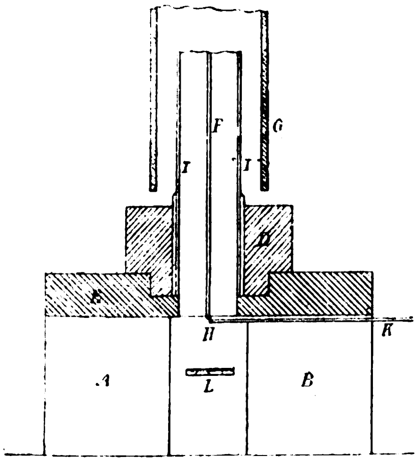

FIG. 5.

To overcome the difficulty of keeping the index at rest, owing to radiation from neighbouring bodies or to draughts of varying temperature, we have surrounded the divided tube by another, which was kept rotating continuously by clockwork. If any part of this guard-tube becomes slightly heated, it is carried round and made to heat the instrument equally all round, and so it produces no effect.

As the determination on theoretical grounds of the most suitable dimensions presents considerable difficulties, we decided to make a series of tubes of different sizes and compare their sensibility. The object of the instrument being to measure the heat developed by the electro-magnetic radiation in a wire within the instrument, it was necessary to make both the tube and guard-tube of some insulating material, such as glass.

The tube to be used was cleaned, and a roll of brown paper about 1in. long was pasted round one end. This fitted tightly into a mahogany ring, D (Fig. 5). The tube was divided longitudinally by a partition of cardboard (F), which was made to fit tightly into the tube. This partition extended from the bottom to within about an inch of the top, which end was closed by a cork.

The projecting end of the mahogany ring (D) fitted into a corresponding hole in a piece of wood (E), which was itself supported on two blocks (A and B). The tube (represented by the dotted circles in the plan, Fig. 6) came directly over this space between A and B, the partition being parallel to their adjacent faces.

Between A B, and immediately beneath the tube, two glass semi-cylinders were placed, with their convex surfaces facing each other. They are shown in plan in Fig. 6 (M N), and one is shown in perspective in Fig. 7. At 2 centim. from the top of one of these semi-cylinders a small paper scale (Fig. 5), divided in half-millimetres, was attached. When a current of air passes from one side of the tube to the other, it has to pass through the narrow space between these cylinders.

A hole was bored through the top of B, through which a capillary glass tube could be passed. This tube was filled with phosphorus, and the glass broken away for about one millimetre, so as to expose a clean piece of phosphorus whenever the stream of oxide had to be observed. The tube was then passed through the hole (K), so that the exposed piece of phosphorous came just beneath the partition and between the glass cylinders. It is shown in place at H in Fig. 5.

By this means the stream of phosphorous oxide was formed at the narrowest part of the air channel, and so was affected to the maximum extent by any passage of air from one side of the partition to the other. The resulting deflexion of the phosphorous-oxide stream could be read with an accuracy of about one-tenth millimetre. In this form, when the phosphorous index is deflected it is carried to a part where the channel is much wider, owing to the curvature of the glass half-cylinders. On this account the deflexion of the index is not any simple function of the rate at which the air is passing. With a view to do away with this want of proportionality, and also, if possible, to render the instrument more sensitive, the glass half-cylinders were replaced by a pair of narrow flat glass plates, near together, with a wide channel on each side communicating with the tube above. The instrument was, however, found to be less sensitive in this form than when the half-cylinders were used.

The sensitiveness of the instrument could, to a certain extent, be altered by moving M and N (Fig. 6) further apart, so that the phosphorus stream fell in a wider channel.

The divided tube was surrounded by another glass tube (G, Fig. 5), which was about 10 centimetres longer. This formed the guard-tube, and was suspended from one of the axles of a clock (K, Fig. 11), which made one revolution in about eight seconds.

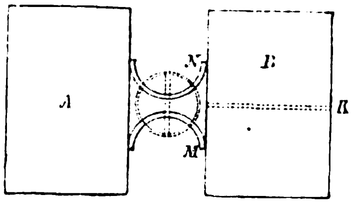

FIG. 6.

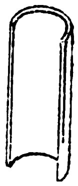

FIG. 7.

By means of three levelling-screws the guard-tube was made to hang free of the inside tube, so that it did not touch it at any part of its revolution. Thus no heat due to friction was developed near the divided tube.

The phosphorus could not be placed at the top of the tube, as the falling column of oxide was found to go on one side of the partition, and its weight was sufficient to keep up a down-current of air on this side and an up-current on the other side, and so make the instrument unstable.

Inside the divided tube, and on one side of the partition, two fine platinum wires were stretched, reaching from the top to the bottom. They were connected together at the top, and at the bottom were brought out and connected to two binding-screws fixed on the ring D (Fig. 5). By means of this wire, whose resistance was measured, a known amount of heat could be developed in the tube by passing a current of known intensity. The current was, in all the experiments, supplied by a single Daniell cell, which contained in its circuit, beside the wire of the instrument, a resistance-box and a key.

The clock was kept working for about half an hour before the commencement of an experiment, in order to equalise the temperature within the tube; and then a fresh piece of phosphorous was introduced. When the phosphorous index was quite steady, and approximately at the centre of the scale, the reading was taken (zero-reading), then resistance was unplugged in the box, and the current passed till the index had again come to rest. The current was then stopped and another zero-reading taken.

In testing the different tubes the largest resistance which would give a readable deflexion was in each case ascertained. The resistance of the cell and the connecting-wires could be neglected in comparison with the external resistance.

In the different tubes the total heat developed was not the same when the same current was passed, as the wires were of different lengths. This, however, was not taken into account in comparing the tubes together, as for the measurement of the electro-magnetic radiation it was necessary to get the greatest possible sensitiveness per centim. of the wire.

It is hardly necessary to give particulars of the different tubes experimented upon. It is sufficient to say that, while the length of the tube was of little consequence, it was found that a wide tube was much more sensitive than a narrow one. The results obtained in a particular case are given.

Tube No. 3:—Length 82, diameter 5 centimetres. Resistance of wire 29 ohms; outside resistance 500 ohms. Deflexion 1 millimetre.

To calculate the amount of heat corresponding to this deflexion, we have, taking the E.M.F. of a Daniell cell as 1 volt,

$$\text{Heat developed per sec.} = \frac{RC^2}{4\cdot 2}$$

$$= \frac{29}{529^2} \times \frac{1}{4\cdot 2} = \cdot 000{,}024 \text{ calorie}$$

over the whole length of the tube, or ·000,000,3 calorie per centimetre of the tube.

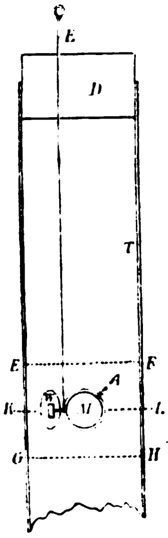

Fig. 8.

While this very small degree of heating was within the range of experimental certainty so long as the clockwork was going, it was impossible to keep any index visible at all when the clock had stopped, even though several concentric screens were placed round the tube.

The apparatus in this form was subject to the great fault that the phosphorous refused to form the oxide at a temperature below 15°C., which prevented the instrument being used on many days.

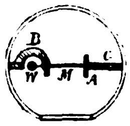

Fig. 9.

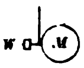

Fig. 10.

With the view of getting over this difficulty with the phosphorous index, and if possible of obtaining greater sensitiveness, a form of index was adopted which was a modification of Dr. Joule's arrangement.

The tube was closed at each end, the partition reaching right up to the cork at the top and leaving a space of about 15 centimetres at the bottom. Twelve centimetres below the top of the partition a hole was punched in the card. Into this hole a short cylinder of paper was glued. This is shown at A in Figs. 8 and 9. A plane mirror, M, fitted into this tube, allowing about one millimetre clearance all round. It was fastened to a cross bar, at the other end of which a counterpoise (W) was fixed.

The mirror and counterpoise were suspended by a fine quartz fibre from a pin (E, Fig. 8), which passed through the cork used to close the tube. When the mirror is at rest it almost completely fills up the hole in the partition, and forms a very delicate means of detecting any differences of pressure in the air at the two sides of the partition.

A small recess (B, Fig. 9) was made in the partition for the counterpoise, and covered in so that it was not exposed to the current of air. The arrangement is shown in elevation in Fig. 8, and in section through K L in Fig. 9. Fig. 10 shows the mirror and counterpoise separately. A hole was ground in the tube immediately in front of the mirror, into which a lens of a metre focal length was cemented.

In this form of the instrument the guard-tube, if continuous, would have prevented the formation of a clear image. It was therefore necessary to divide it into two portions. Rings of mahogany (N, Fig. 11) were cemented to the top of the lower portion and to the top and bottom of the upper. The two rings $N_1$ $N_2$ were connected together by three bolts, of such a length as to leave a space of about two centimetres between the rings. This break in the guard-tube came just on a level with the mirror, and thus allowed the beam of light to pass freely. The passage of the bolts before the mirror produced no inconvenient effect on the image

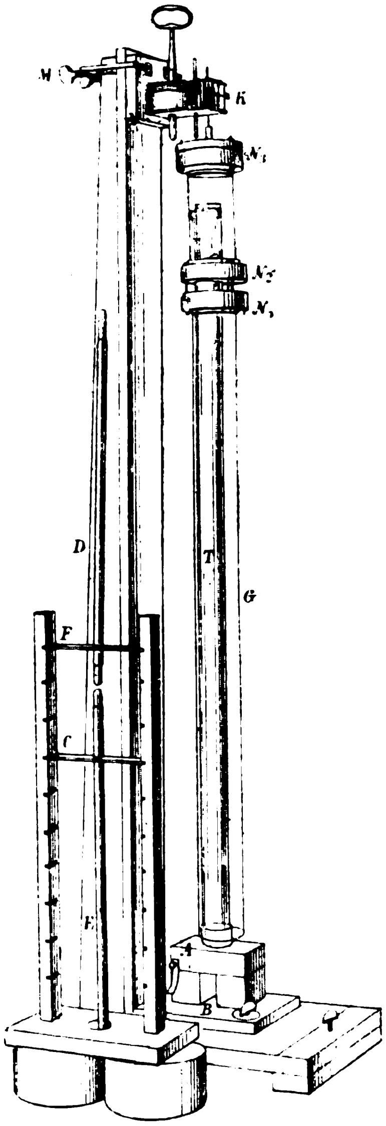

Fig. 11.

formed on the scale. The ends of the wire were brought out at the bottom of the tube, leaving about half an inch free. When using a continuous current, two brass clips (A, Fig. 11) were placed on these ends so as to connect them to a pair of binding-screws. When using the oscillator these clips were turned down (as in the figure), so that the wire should not be connected with any body having capacity.

The following are the dimensions of this tube (No. 4):—

Length 126 centimetres, diameter 4·7 centimetres.
Length of wire 2 × 103 centimetres.
Resistance of wire 38 ohms.
Diameter of guard-tube 7 centimetres.
Diameter of mirror 1·2 centimetre.
Length of fibre 9 centimetres.

As shaking interfered with the working of the instrument, the experiments were performed in a vault, which, however, was by no means steady.

Digitized by Google

The following are the results obtained when testing the sensibility of the instrument (scale at 100 centimetres from mirror):—

| Added Resistance. | Total Resistance. | Deflection. |
|---|---|---|
| ohms. | ohms. | centimetres. |
| 500 | 538 | 3·3 |
| 762 | 800 | 1·6 |

In the case of 800 ohms total resistance we have

$$\text{Heat developed in wire per sec.} = \frac{1}{\overline{800}^2} \times \frac{38}{4\cdot 2}$$

$$= \cdot 000{,}014 \text{ calorie.}$$

This is equivalent to one calorie developed in 19hrs. 42min. Or we may say that one calorie per day developed by the whole wire could certainly be detected; that is, one calorie in 103 days per centimetre of tube.

The oscillator used to set up the electro-magnetic radiation consisted of two hollow brass cylinders (D E, Fig. 11), fixed to ebonite cross pieces (F, C), which could be placed at different heights in a wooden stand. Short brass cylinders, with well-rounded ends, fitted into the ends of D and E, and allowed the length and sparking distance to be altered. These cylinders were connected by very fine wire with the terminals of the large Ruhmkorff's coil belonging to the Physical Laboratory. The length of the oscillator was the same as that of either of the wires in the tube, and it was placed so as to be in the plane of the partition of the tube, at a distance of about 30 centimetres (Fig. 11). The best length of spark was about half a centimetre.

At first, on separating the knobs of the oscillators, so that no spark passed, the instrument showed a large deflection in the direction of cold. This was due to electrostatic attraction between the oscillator and the mirror. To prevent this action a piece of tin-foil (E F G H, Fig. 8) was pasted round the tube at the level of the mirror, a hole being cut in it the size of the lens, which effectually put a stop to this action.

The instrument now indicated a considerable amount of heat developed in the wire whenever the coil was worked.

The effect of altering the capacity of the oscillator by adding pieces of tin-foil to the ends was tried, but with no beneficial result.

A wet duster was hung between the oscillator and the instrument for the purpose of seeing whether the radiation would pass through. The deflection produced was only slightly less than when no duster was interposed.

In order to measure the heat developed by the induced currents in the wire, the deflection produced when the coil was worked was noted; then a steady current was sent through the wire, and the resistance in the circuit altered till an equal deflection was obtained. The readings obtained with the oscillator were somewhat varied, owing to small changes in the character of the sparks. Another difficulty was caused by the coil often refusing to work continuously for the time necessary to get a reading (about 1½ minute), as the contact-breaker became burnt by the sparks.

The following are the deflections obtained in centimetres:—

45; 44; 37; 36; 35·6; 36·9; 44·8; 45·5; 40·2; 40·2; 39.

*Mean* 40·4 *centim.*

One Daniell cell working through a total external resistance of 115 ohms gave the following deflections:—

41·0; 40·0; 39·3; 40·0; 41·0.

*Mean* 40·3 *centim.*

We may therefore say that the heating effect due to the oscillations (oscillator at 30 centim.) is equal to that produced by one Daniell cell when the external resistance is 115 ohms, and the working resistance 38 ohms.

Therefore the heat produced per sec.

$$= \frac{38}{\overline{115}|^2} \times \frac{1}{4\cdot 2} \text{ calories,}$$

$$= \cdot 000{,}685 \text{ calorie;}$$

or it would take 24 minutes 20 sec. to produce one calorie.

The steady E.M.F. between the terminals of the wire which produces the same effect as the oscillations is ·33 volt. Mr. Gregory gives ·5 volt as the equivalent E.M.F. in his experiments. Though the conditions were not sufficiently similar to make the numerical results strictly comparable, nevertheless the fact that the figures obtained are of the same order goes to show that the expansion observed by Mr. Gregory was a true expansion due to heat, and that his results were real.

In calculating from the heat developed the mean square of the current produced in the wire by the electrical oscillations, it is necessary to take into account the fact that these rapidly alternating currents are not uniformly diffused throughout the cross section of the wire, but only pass through a thin stratum at the surface. On this account the resistance which the wire offers to these rapidly alternating currents is greater than that which it offers to steady currents.

Lord Rayleigh* gives a formula for calculating the effective resistance of a wire of round section to an alternating current of given frequency. It is

$$R' = \sqrt{(\tfrac{1}{2}pl\mu R)},$$

where R′ is the effective resistance; R the resistance to steady currents in C.G.S. units; $p2\pi$ times the number of oscillations in one second; $l$ the length of the wire; and $\mu$ the magnetic permeability of the substance of which the wire is composed.

In the following calculation one of the wires only is considered.

The length of the primary oscillator is 109 centimetres, and therefore the wave-length of the radiation given out is 218 centimetres. If $n$ = number of oscillations per sec., then

$$n = \frac{v}{\lambda} = 1\cdot 376 \times 10^8.$$

The length of the wire ($l$) is 103 centimetres, and its resistance 19 ohms = $19 \times 10^9$ C.G.S. units.

In the case of platinum $\mu$ may be taken as unity.

From this it follows that

$$R' = 29 \text{ ohms},$$

and since H (half the heat developed in the two wires) = ·000,342 calorie per second

$$C^2 = \frac{J\,H}{R'}$$

$$= \cdot 000{,}049.$$

Owing to the harmonic distribution of the current along the wire, in order to produce a given amount of heat in the whole wire, the strength of the current at the centre must be $\sqrt{2}$ times as great as that which would be necessary if the current were of uniform strength in all parts of the wire.

∴ the square root of the mean square of the current at the centre = ·01 ampere.

While it is impossible from the heat found to form any conclusion as to how fast heat was being generated during each spark, or what fraction of the whole time the oscillations lasted, yet here, as in the former case, the final result depends on the mean square of the current. We found by the first method that the square root of the mean square was certainly not ·003 ampere, if the theory was correct; while by the heat we find the square root of the mean square to be ·01 ampere. The arrangements in the two cases were not strictly comparable, for in the first the oscillator was only 30 centimetres long, while in the second it was 109 centimetres, and because the distance of the primary from the secondaries was relatively greater in the first than in the second case. We intended to have made a second set of measures in which the suspended cranked oscillator should itself be in the tube of the convection-thermometer together with the fixed cranked oscillator. In this way the force, if any, between them could be observed and measured at the same time that the deflection of the mirror due to the heat was read; then, by making contacts with the ends of the fixed cranked oscillator alone, and passing a current through it so as to produce the same deflection, all the data would be obtained to tell for certain whether the absence of force, or, if force was observed, if the actual force was that which the provisional theory set out at the beginning of this Paper indicated. The discrepancy of 3 : 10 in the present instance cannot be taken as proving that the theory is wrong, and that the forces ought not to be observed, but it does clearly show that they must be excessively minute, and that, if they exist, it is only by great refinement that they can be made evident. No doubt, as Prof. Fitzgerald suggested, the use of concentrating cylindrical mirrors of proper form would greatly increase the sensitiveness of the whole apparatus.

We have been prevented from completing this work because the elementary laboratory was required, and it is impossible to carry on any really delicate research requiring uniform conditions and steadiness in so unsuitable a building as the Science Schools. We have, therefore, published our results in their present imperfect condition, partly because we believe that the methods employed may be useful to others, but chiefly because we hope that some physicist who has the advantage of having a steady underground room may be induced to make the experiments under more perfect conditions, and so carry the matter to a successful issue.

## PRESENTATION PORTRAIT OF SIR JOHN PENDER.

A luncheon was given by the Eastern and Associated Telegraph Companies at Winchester House, on Tuesday, the 13th inst., on the occasion of the presentation, on behalf of the late Lady Pender, of a portrait of Sir John Pender, K.C.M.G., by Prof. Herkomer, A.R.A., to be placed in the Board Room of the Companies.

The following gentlemen were present:—The Marquis of Tweeddale, Sir John Pender, K.C.M.G., Sir James Anderson, Admiral Sir G. Richards, K.C.B., Admiral Hon. Sir H. Keppel, G.C.B., Lord Sackville A. Cecil, Sir A. L. Cappel, K.C.I.E., Sir H. D. Gooch, Bart., Hon. St. John Brodrick, M.P., Sir Henry Mance, G. G. Nicol, Esq., John Denison Pender, Esq., W. Andrews, Esq., W. Shuter, Esq., T. Fuller, Esq., William Ford, Esq., James Pender, Esq., L. Floersheim, Esq., E. M. Underdown, Esq., Q.C., R. K. Gray, Esq., C. W. Earle, Esq., C. W. Stronge, Esq., K. Anderson, Esq., G. Draper, Esq., F. E. Hesse, Esq., W. Payton, Esq.

Sir JAMES ANDERSON read the following letter, which he had received from Sir John Pender:—

"The Eastern Telegraph Company (Limited),
Winchester House, 50, Old Broad-street,
London, E.C., December 17, 1890.

"MY DEAR SIR JAMES,—You were Chairman of the Committee which gave a banquet in my honour in 1889, and on that occasion, memorable to me, you and my friends gave a portrait of myself to Lady Pender, which she much valued.

"It was her strong desire then to give as a memento in return another portrait of myself, to be placed in the Board Room of the Companies with which, as first Chairman, I have been so long associated.

"I have now the pleasure to carry out her wish, and I beg the Boards' acceptance of the picture by Professor Herkomer, being a portrait of myself, which I believe has been generally acknowledged to be a good likeness.

"I hope it may continue to hang in the Board Room, and that those who may hereafter fill the position which I have so long occupied, and with so much pleasure still occupy, will recognise what the Boards have done by perfectly harmonious working in carrying to a successful issue a work which probably has played the most prominent part in bringing into closer communion the nations of the world, and in causing a more rapid development and progress of their political, social, and commercial life.—Believe me, yours faithfully, "(Signed) JOHN PENDER."

Sir JAMES ANDERSON then said: I do not think I ought to add many words, as Lord Tweeddale will accept the picture on behalf of the Companies; yet I cannot help recognising a certain sentiment about the occasion. All who had the pleasure of knowing the late Lady Pender must remember the interest she universally felt in the way those associated with these Companies had developed this new enterprise. It seems to me that we are erecting a kind of memorial upon the track of this great movement, and that this picture is the first historical portrait of the members of the cable combination. No one can say to what degree of importance this network of submarine cables may expand, and who knows that the younger members in this room may not yet see some great telegraph hall erected in which this may be the pioneer portrait and one of the best hung on its walls. At all events, I would say that whoever of you younger gentlemen may come forward and take up the reins which others will in the course of nature have to lay down, you will have to go straight ahead very much as we have done. Since ocean telegraphy was commenced, there has been no flagging. All this time your Chairman has followed the flag wherever commerce went, and I think if we had not followed the flag the flag must have followed us. When your time comes I can only wish you every success in your endeavour to do this, and I will now leave it to Lord Tweeddale to accept the picture in our name.

The MARQUIS OF TWEEDDALE: I have been entrusted with the agreeable duty of accepting on behalf of the Directors who occupy this Board Room the portrait which you see before you. The idea of presenting the portrait of our Chairman to these Companies originated with the late Lady Pender, who, as Sir James Anderson has told you, took from the very first to the very last the liveliest and most intelligent interest in the prospects and prosperity of submarine telegraphy. I deeply deplore her loss, because I know the gratification with which she would have received your thanks for her generous gift. I am happy to think that so many of us have been permitted to meet here to express our acknowledgments for the splendid portrait which hangs on the wall. We have to thank Sir John Pender for the manner in which he has carried out Lady Pender's wish, and to tell him that we appreciate the gift, not only for its intrinsic merit as a work of art of the highest order, but as an excellent and faithful likeness of himself and as recalling the features of the man who has guided our counsels for nearly 22 years with rare courage, energy, and success. In such a company as this it is not necessary for me to dilate upon the importance of the enterprise with which Sir John Pender's name will be long and honourably associated. It is not, however, exaggeration to say that every department of life throughout the world has been thereby profoundly affected, whether it be socially or commercially, or whether we regard it from a national or international point of view, and I venture to think that when the history of the latter part of this century comes to be written no enterprise will occupy so prominent a position as that of the development of submarine telegraphy, and that no other name will be so closely associated with it as that of Sir John Pender; because without for a moment wishing to undervalue the services of others who have worked in the same field, I think you will agree with me that to no other single individual is due in so large a degree the successful development of that enterprise. Therefore, gentlemen, I will now ask you to join in the expression of a warm and hearty hope that he may live long to occupy that position which he fills with such conspicuous ability, with so much advantage to the interests entrusted to him, and with so many benefits, not only to this country, but to the world at large.

Sir JOHN PENDER: My Lord, Sir James Anderson, and gentlemen, speaking, as I do, before men who have played alongside of myself an important part in the great ocean system of telegraphy, you can well understand that I speak under a feeling of considerable diffidence. Looking back upon the period that we have been associated together, there are points which strike me as remarkable, and as fore-shadowing the success of that great enterprise, although, when I remember our earlier public meetings, I feel that they were very much like ordinary meetings of that kind. There were some who were not quite conspicuous for their conduct as gentlemen, who pretty roundly accused us of doing everything but that which was straightforward. I think, gentlemen, we have lived all that down. We have shown to the world the great success of the enterprise. I believe I may say that no undertaking was ever carried out more successfully, more honestly, or with a more earnest desire to benefit the community at large than that of the Companies over which I have the honour to preside. I am, and always have been, anxious that those who are behind us in years and experience may, in the future, carry the standard as high as we have carried it, and if they continue that course they will find their reward will be very much the same as ours—not only a reward conferred by crowned heads, but a reward bestowed by the approbation of the keenest intellects of the day. There is no Prime Minister either in this country or in any part of Europe who has not acknowledged the great importance of what we have done. It seems like praising ourselves; but there is still, as Sir James Anderson has said, work to be done, and that work will have to be accomplished by harmonious and united action. During the twenty years that I have presided over these Boards I do not remember a single division in the voting. We always managed to make matters go in the right course before we attempted to vote on them. We have thrashed out everything to the satisfaction of every Director, and the result has been united action in carrying matters through. Now, gentlemen, I think I have said enough, but I cannot conclude without saying that I am very proud of the Companies over which I preside, very proud of the great amount of support which I have received from gentlemen sitting at this table, as well as from those who preside over other cable companies, and who are as devoted to the service of those companies as we are to those with which we are connected. I have had a vast amount of support all round from everyone connected with the submarine system, both from those engaged in working the cables and from those engaged in manufacturing them, with which I had something to do in my earlier days. I now come to a point which is to me most touching. My wife was greatly interested in and proud of the growth of this system and of her husband's connection with it. She expressed a wish that when I had passed away I might be still represented in the Board Room in which I had so long presided. She said she should very much like to present my portrait to the Companies. That brings me to-day to thank you all for so gracefully accepting it as from her. Once more I thank you, gentlemen.

Sir JAMES ANDERSON said that letters had been received from Lord Monck, Sir Thomas Fairbairn, Sir George Elliott, and Sir Leopold Heath regretting their inability to be present on account of the state of their health.

After some remarks from Lord SACKVILLE CECIL in acknowledgment of the kind remarks made in reference to the younger Directors, Sir JOHN PENDER proposed a vote of thanks to the Chairman and the proceedings terminated.

## THE ELECTRIC LIGHTING OF DUBLIN.

A meeting of the Dublin Corporation was announced for Monday last to consider the tenders of various English and Irish firms for the electric lighting of the city, but owing to the death of a member of the Corporation the meeting was adjourned without any business being done.

The tenders, 18 in number, were opened on November 1st last. The specifications were on two schemes—one on the assumption that a central station was put down with sufficient plant to provide current for 80 arc lamps of about 1,000 candle-power each; and 3,000 incandescent lamps of 16 candle-power each; the other on the assumption that power was provided for the same number of arc lamps for the public lighting, but with sufficient power and enlarged mains for the supply of current to 5,000 lamps of 16 candle-power each for the private lighting.

These tenders were referred by the Special Committee having the electric lighting in charge, to the Borough Surveyor (Mr. Spencer Harty), and to Mr. Manville, electrical engineer, for analysis and report. In the course of their report these gentlemen state that "the complete tender of the Electrical Engineering Company of Ireland, inclusive of the dearest engines of the three types named by them, and amounting to £28,907, without buildings, is, perhaps, the most complete total tender, at a moderate price; but in the event of your deciding to accept this tender for all sections, we recommend that they be asked to reconsider their system of main laying."

The Special Committee recommend for acceptance the tender of the Electrical Engineering Company of Ireland, based on the

Digitized by Google

original specification, inclusive of buildings, but with the alterations as to main laying recommended by the engineers, viz., that cast-iron pipes and vulcanised rubber cables shall be used, and also lamps of the Brockie-Pell pattern for the lighting of the streets.

With these alterations the Company are willing to execute the works for £30,714. The Company also offer to undertake to run the entire station and the 80 arc lamps for a year for £4,000, plus 7½ per cent. on the gross revenue derived from the private lighting, and the Committee state that consideration of the estimates indicated that the acceptance of this offer would be of advantage to the Corporation.

## AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January* 2, 1891.

**The Position of the Westinghouse Company.**—The Westinghouse Electric Company seems to have been in great need of ready cash recently, inasmuch as extraordinary efforts were made by Mr. Westinghouse to negotiate a loan of half a million dollars to tide over present embarrassments. These efforts were successful, although the makers of the loan required Mr. Westinghouse's personal security in the way of mortgages and collateral. There is no reason for believing that the Company is in any way insolvent, or in danger of becoming so. The simple truth being that it has extended its business so much that its capital has been tied up, and unavailable for immediate needs. The introduction of the electric railway system has been a source of very large expense to the Westinghouse Company, and other new departures have called for a very large amount of capital. The railway department will doubtless prove a good and paying investment, but it caused a severe strain on the resources of the Company.

**The Municipal Rapid Transit Question in New York.**—The rapid transit question in New York is again being vigorously agitated by the daily press. The recent successful inauguration of the City and South London Railway has been a decided stimulus to American engineers in attacking the same problem here; but the difficulties to be met are so great that a happy solution of the present difficulties may be very far off. Unfortunately, the cable-railway scheme, which will shortly be put into execution on Broadway, will, if carried out as contemplated, interfere with any subway work on that street, unless it is carried far below the level which might otherwise be necessary. The most practicable plan as yet suggested for rapid transit is one that contemplates the construction of a four-track substructure, reaching from near the battery to the extreme northern end of Manhattan Island, but passing considerably to the east of Broadway, and through a portion of the city where the injury to property and consequently expense of construction would be very much less than if the same enterprise were to be conducted on more important streets. The particular part of the city selected for the execution of such a plan is, however, of very little importance, for provided the subway should extend the whole length of the island it would do its work effectively enough, as the width at no point is so great as to make branch lines necessary. As the case stands at present, something of this description must be done, and done in a very few years if the city is to continue its present rate of growth. Standing on the Palisades opposite the north end of Manhattan Island, hardly a trace of the existence of a great city can be distinguished within easy view. Far to the southward lies the smoke and haze that surrounds the metropolis, but the upper end of the island is to all appearance deserted, and simply for the reason that it is quite inaccessible for residences. As a result a large part of the increase in population at present overflows into Brooklyn and the towns and cities that lie conveniently near in New Jersey.

**The American Telegraph System in a Fog.**—An unwonted difficulty with telegraph lines through a large part of the country has marked the bad weather of the last week. The severe and widespread snowstorm of Christmas week interfered considerably with telegraphic service, but its effect was as nothing compared with the demoralisation produced by a fog over a large portion of the Middle and Western States a few days later. For a single night telegraphic communication was very seriously interrupted; hardly a line was in working order, and the few over which signals could be obtained at all were working badly. The Associated Press lines from this city as far west as St. Paul, Minn., were, for the time being, crippled. The length of our Trunk lines is so great that when wet weather is general throughout their extent leakage makes a successful working almost impossible. The unpleasant phenomena observed may be more frequent with you in England, but they are almost unique here.

**A New Submarine Boat.**—A submarine boat is reported as being in process of construction in Detroit, Mich. It is a comparatively small affair, not by any means so large as the La Gymnote, of Continental fame, but like it, is to be operated by storage batteries. A peculiarity, however, is that its normal position is just at the surface, and it is held submerged only by the action of a screw, so that in case of any accident, instead of remaining at the bottom, the boat will promptly rise to the surface.

## CORRESPONDENCE.

### THE BYE-LAWS OF URBAN AUTHORITIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The power granted to Urban Authorities by the Public Health Act, 1890, of making bye-laws with respect to wires placed above ground, which was referred to in your Editorial Notes last week, does not threaten any serious obstruction to electric lighting interests. Any such bye-laws, if made, can have but a very limited operation, since the wires of "undertakers," under the Electric Lighting Acts, are expressly exempted from their operation.

The progress of legislative interference with overhead wires has been somewhat spasmodic, so that it is not surprising if some misapprehension on the subject exists. The Electric Lighting Act of 1882 forbade "undertakers" to lay their wires above ground without the consent of the Local Authority, but left untouched those erected by persons who had not obtained Parliamentary powers to supply electricity. The Electric Lighting Act of 1888 for the first time brought the wires of these outsiders under the control of the Board of Trade. The regulations framed by the Board under that Act apply to the wires of such persons only, and although these have since been almost entirely incorporated in the more extensive regulations issued last year to "undertakers," yet it must not be assumed that the former have become merged in the latter for all purposes, since the two sets of regulations are issued under different Acts and apply to different classes of persons, and must, therefore, maintain independent existences.

The Act of 1888 did not extend the power of vetoing overhead wires, nor the power to make bye-laws for securing public safety, both of which were given to Local Authorities by the Act of 1882 in respect of Parliamentary undertakings, so as to make either of these powers applicable to the wires of outsiders. Thus, while the principle had been admitted of allow-

Digitized by Google

ing Local Authorities a control in such matters, there was an apparent anomaly in applying it only to those cases in which it is probably least likely to be required, namely, those of "undertakers" who are already very strictly tied up by Parliament.

This inconsistency has been now removed by the clauses on the subject inserted in the Public Health Act of last year, to the extent of allowing bye-laws to be made in respect of un-Parliamentary wires, though the Act does not give power to absolutely prohibit these being carried overhead. The reason for this omission, no doubt, is that these clauses are, as you surmise, principally directed against telephone wires, and we are not yet ready for a general decree that these must be buried.

Under the Acts both of 1882 and 1890 confirmation by the Board of Trade is necessary to give validity to any bye-laws which may be framed. No such confirmation has hitherto been granted in any case; and so far as I am aware the only application ever made for such confirmation was that of the Bradford Corporation, which did not receive the desired sanction.—Yours truly, A. C. CURTIS-HAYWARD.

27, Chancery-lane.

## THE CITY AND SOUTH LONDON RAILWAY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the last issue of your journal you state:—"During the first fourteen days ended on Saturday last the receipts amounted to £1,947, showing that 233,640 passengers had been carried during that period, or on an average 16,688 per day; that is to say, nearly 40 per cent. more than was estimated by the pessimistic Mr. A. Willbond." This is all very well in its way, and might have passed muster amongst your readers were it not for the extraordinary fact—which seems to have escaped your attention in making up—that you have yourself discounted your own figures by stating that it must "be borne in mind that novelty is only a temporary attraction, and that comfort and regularity will alone secure permanent patronage."

The figures given by me in the *Electrical Review* were based upon permanent traffic, and I have found when travelling on the railway in question that the actual number of passengers carried was on several occasions only a *very small* percentage higher than given in my estimate. "It is, moreover, to be borne in mind that novelty," which "is only a temporary attraction," was at that time still temporarily attracting.

I hope that your readers who have read the two leaderettes in question will find my letter at least a "temporary attraction."

When about to post this letter, I find that the official returns for last week's traffic give the total receipts as £748. Thus, notwithstanding the "temporary attraction," the average number of passengers carried per day was only 12,823, or about 7½ per cent. more than the number given in my estimate.—Yours truly, A. WILLBOND.

London, January 13, 1891.

## THE NEW ELECTRIC AND MAGNETIC THEORIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As Mr. O. Heaviside proposes to give us an explanation of electro-magnetic theory in language that may be understanded of the people, may I make a request in the name of that, I believe, large class called by Prof. Silvanus Thompson "half educated electricians," called so, not because they have not acquired a complete knowledge of the subject (in that sense we are all very fractionally educated), but because they have not surrendered the teachings of experiment, the belief that Ohm's law represents actual facts of nature, and the faith that electric currents are conveyed by the "so-called conductor."

What I would ask for is the evidence, proof that electric and magnetic propagation are effected by "ether" and not by common matter. I have never yet seen any better answer to the sceptic on this matter than that which Prof. Poynting said some time ago was the only answer he could give, that the said sceptic was a very disagreeable person. Mr. Heaviside now begins by making the assertion (p. 258) that the etherial theory is proved; but, as far as I can find, it is simply asserted, or taken as proved. As far as I can see the Hertz experiments prove nothing. They only have given experimental proof of what is self-evident, viz., that periodic impulses of any sort which rise and fall in intensity must develop a wave motion; that they show such a motion in the ether is only an assertion, which people who do not believe it do not trouble themselves to dispute.

The argument is that these motions are of an order of which ordinary matter is incapable. I propose to show that if there is anything which we can be said to know, when it is beyond our direct observation and examination, it is that *ordinary matter does constantly maintain these very motions*, viz., vibrations analogous to those of light.

The origin and basis of the ether theories is, after all, the fact of transmission of light across space, where ordinary matter cannot exist. The hypothesis was therefore framed that space contained a something, which, while not possessing any of the properties of ordinary matter, and, as to these, being indistinguishable from pure "nothing," yet transmits light (we may extend this to energy) in the form of undulations communicable to matter. But how do these undulations in ether originate? Undulations in air transmit sound; but these undulations are produced by just the same vibrations first set up in solid matter, wires, &c. It is the same with light: the ether undulations are produced by motions of exactly the same order in the ordinary matter of the luminous bodies. The spectroscope tells us that the ultimate atoms of matter are all executing motions which are imparted to the surrounding agent of transmission. The real truth which light teaches us is, not the undulation of the ether, of which we know nothing at all, but the specific infinitesimal motions of matter, about which we know a great deal.

Who, then, has the right to assert that magnetic and electric wave propagation must be transmitted by ether because the ordinary matter is not capable of such motions? We know that it is capable, and we have no evidence of any sort that the ether is capable of transmitting either magnetism or electricity. We know that light crosses space, and it is very certain that neither electricity nor magnetism do.

As to this point, which is of much importance, because it is often supposed that these forces do traverse space, and produce magnetisations in the earth simultaneously with visible solar disturbances, I must refer to the principles first set forth, p. 444, of the 2nd edition of my "Electricity: its Theory, Sources, and Applications." I there pointed out that electric charges could not exist on the cosmical bodies, or lines of electric force in space, because the consequent attractions and repulsions would produce variations in the apparent action of gravitation which do not exist. The same applies to magnetic force; if it existed in space the planetary axes would most certainly sway about. Besides, it is most probable that no magnetism exists in the sun on account of its high temperature; and even if it did, it would be in the form of closed lines, forming a shell round the sun, and only extending a little way into space.

In the face of these essential facts, and the absolute difference between light, as a straight line, radiant form of energy, and electricity and magnetism as purely dual and forming closed curves, it needs a very highly-developed education to see that they are identical in nature and propagation.

The fact is, that it is only since alternating currents became of practical importance, and the effects at make and break had to be explained and formulated, that these new imaginations became serious; the professors found it easier to invent theoretical explanations than to study natural facts, so they converted our old enemy—retardation—into conduction by the ether. In another letter I will try to show that there is a better way. JOHN T. SPRAGUE.

[Mr. Sprague need hardly trouble so high an authority as Mr. Heaviside with such questions as the above. He will find ample reasons for the ether theory in well-known books. We would refer him to Dr. Oliver Lodge's "Modern Views," p 339, where he will find a clear account of the differences between ether and ordinary matter. It is obvious that matter can vibrate fast enough to produce light, but it is not rigid enough to transmit vibrations at the well-known speed of light. For

Digitized by Google

this purpose it must be about a thousand million times more rigid than steel. Maxwell predicted, and Hertz has proved, that magnetic and electric wave propagations are transmitted at the same speed as light; no known form of matter would suffice. We can only know of things by their appearances, and certain appearances are called the properties of a certain something, and that something we call ether. Mr. Sprague has done considerable service in the production of his well-known book, which, while we cannot endorse it as altogether orthodox, contains much useful information; but he would do well to study the recent advances in electrical science before he begins to treat in so categorical a manner of subjects with which he does not appear to be very familiar.—Ed. *E.*]

## LEGAL INTELLIGENCE.

### The British Tanning Company v. Groth.

This action came on for hearing on Wednesday in the Chancery Division of the High Court of Justice, before Mr. Justice Romer. The Attorney-General (Sir R. Webster, Q.C.), with whom was Mr. Farwell, appeared for the plaintiff company, and Mr. Moulton, Q.C., and Mr. Oswald appeared for the defendant; Mr. Ashton Cross watched the case for parties interested.

The ATTORNEY-GENERAL, in opening the case, said the action was brought by the British Tanning Company (Limited), who were the owners of letters patent granted to French people of the name of Eugène Worms and Jean Balé, the date of the patent being the 5th July, 1887. A point that would arise he ought to mention, viz., that there was a prior publication—which he should not deny would be sufficient to invalidate the patent under ordinary circumstances—of their invention made in England by sending over to the Patent Office an abstract of an American specification a few weeks before their own application; that would be fatal but for the fact that the patent was applied for by a French patentee, and the 103rd Section of the Patent Act provided that a patent should not be invalidated if it were made within seven months of the date of the foreign patent. The patent, as he had said, was dated July 5, 1887, and was for an improved process of and an improved apparatus for the tanning of hides. It had been known for many years that the oscillations or shaking about of hides in the tanning greatly accelerated the process of tanning; that by shaking or rolling about the liquor got more rapidly and thoroughly in contact with the various parts of the hides and permeated the pores of the skins more quickly, therefore tanning proceeded quicker when there was motion, oscillation, or shaking about of the liquor and hides. This had been known for a great many years, and it was also known that a current of electricity had a useful effect in the operation of tanning, though he did not know that anyone could say why that was so; but prior to the plaintiffs' patent there had been no effective method discovered of applying electricity to the operation of tanning. There had been numerous attempts, but they had all failed. The action was peculiar in this respect, that the defendant did not set up or allege any anticipation by prior publication, except the prior publication of the plaintiffs' own invention. This was important when considering that the invention was one of very practical utility and undoubted novelty. Put shortly, the invention was this, that, for the first time, the two necessary elements in the process of tanning, viz., motion of the hides in the tanning liquor and electricity, were brought into combination. As he had said, it was well know that motion, or shaking about of the hides, was good, it was imagined that electricity was good, but there had never been any practical means of bringing into play the force of electricity in the operation of tanning; the two things had never been combined. A French patent was taken out in the month of December, 1886, and Worms and Balé, who were the French patentees, came over to England and engaged the defendant, Mr. Groth, as their agent to push their invention. The defendant had nothing whatever to do with tanning, and had never been engaged in a tanning business, in fact, he was a gentleman of commercial skill and ability, and for a period of five or six months was engaged in endeavouring to push through or to bring out a company for the working of Worms and Balé's invention. In October, 1887, two gentlemen were sent over to France by the defendant in order to see the invention in operation, and from their inspection it was seen that the invention was going to be a successful one. From a practical point of view the result of the invention was most remarkable. It would be proved by expert witnesses that whereas tanning under the best process prior to the invention used to take from six to eight months, under Worms and Balé's patented process it could be done in something like from 48 to 72 hours. This remarkable shortening of time was the result of the combination of motion and electricity. That being the case, it was evident the invention was one that was likely to attract attention, and one which those in the business would be glad to avail themselves either as licencees or by means of an infringement. In the invention the hides were put into a revolving cylinder or barrel, being hung upon hooks or pegs. The tanning liquor was then put in, and fresh tanning liquor could be put in through the axle of the revolving barrel. Around the outside of the barrel were two bands of copper, and from a dynamo a current of electricity was brought to the two terminals on the barrel connected with the copper strips. The current passed from one copper strip to the other, and into the barrel, where there were other copper strips, and in this way the current was passed through the fluid, which was revolving all the time. The consequence was that the hides were constantly shaken about, and the electric current passed through the liquor from one electrical to the other. He would ask his lordship to look at the specification of Worms and Balé's patent, as an anticipation of it had been set up by the defendant, the anticipation being an abstract of plaintiffs' own invention. The learned counsel then read the specification of Worms and Balé, and stated that under it they claimed two things, the process of tanning rapidly by subjecting the hides to oscillation by a drumming motion, and the passing of an electric current through them at the same time. With reference to the invalidity, he thought that matter could easily be disposed of. The particulars of objection which were filed on January 6th stated that an abstract of the patent had been published in this country prior to the date of the patent. With regard to the publication, he did not think his learned friend could prove anything as to the publication of a complete specification; and as to the abstract, it should be borne in mind that that was an abstract of the plaintiffs' own patent and had been sent over by someone in the United States. It was a most useful and completely successful invention, and it was impossible for the defendant Groth to point to any anticipation by prior publication, or anything else that would invalidate it, except this publication, which was an abstract of his own invention. Mr. Groth, the defendant, was an agent of Messrs. Worms and Balé, but difficulties arising between them the agency was revoked, and thereupon Mr. Groth set to work to avail himself of the knowledge he had obtained from the plaintiffs' invention to infringe the patent or, as Lord Justice James said of infringers, looked round to see how he could get the real merit of the invention without imitating it. The defendant's apparatus had been seen at work at the Grange Works, Bermondsey, by witnesses that he (the Attorney-General) should call, and they would state that there was practically no difference between the working of the two. Upon the whole case he should ask the Court to come to the conclusion that an infringement of a most useful apparatus had been made by the defendant. He admitted that in April, 1887, prior to the date of plaintiffs' patent, there was a publication of the invention by an abstract sent over from the United States; but he submitted that as the plaintiffs were foreigners they came within Section 103 of the Patent Act of 1883. There was not the slightest doubt that the patent was vested in his clients, and without taking up further time he would call his witnesses.

Mr. JUSTICE ROMER: Is that the only point?

Mr. MOULTON: The two points really are the question of the prior publication and the infringement, and my learned friend the Attorney-General has admitted that the question of prior publication turns upon Section 103.

The ATTORNEY-GENERAL then put in a copy of the French patent dated 14th December, 1886, and taken out by Eugène Worms and Jean Balé.

Prof. WILLIAM CROOKS, scientific chemist, was then called, and said that he had considered the plaintiffs' specification from a scientific point of view, and found that it was really an important invention, as under its operation oxhides could be tanned in a space of 80 hours, as against from 5, 6, and even to 14 months as was formerly the case. The application of the current of electricity while the hides were being moved about in the liquid gave a fresh surface of liquor to the hide, and thus prevented their remaining in a liquor (as in pits) which practically got used up. The construction of the drum was well known, and he did not see that anything was gained by the rotary motion of the drum.

In cross-examination by Mr. MOULTON witness said he had not seen the alleged infringement prior to the action, and he had never been connected with tanning, though the process of tanning had been brought to his attention during his scientific pursuits. He believed that one invention as applied to the process of tanning was a rotatory drum, and that it was well known. He was not a practical tanner, and therefore could not say that it was claimed for it that the rotatory motion had a salutary effect. When electricity was not applied to the operation of tanning it was not important to move the hides more than once a week, or once a month; but when electricity was applied it was necessary to keep them constantly in motion. Passing electricity through a stationary vat would have the same effect as in the plaintiffs' invention. There was nothing in the defendant's specification to show an intention to claim the force of electricity with any other method than that of a horizontal drum. In the French specification it was admitted that the application of electricity to the process of tanning was useful, and generally so acknowledged, and that the use of rotatory drums was economically advantageous. In the plantiffs' process the hides in the drum were rolled over and over by the means of pegs sticking radially inwards, and thus the tanning liquor was generally diffused amongst them. In the defendant's process the hides were stretched on pegs or bars, and kept in that position as they revolved in the liquor. He did not see the difference between the defendant's apparatus and a vertical drum with some of the staves left out put in a pit. There were plenty of other processes which an electrician could devise in which the barrel principle need not be used. He could not mention one on the spur of the moment that would be outside Worms and Balé's invention. The motion might be up and down. He could not say whether that would be within Worms and Balé. In plaintiffs' process the electricity would go through the hides in the same way generally, unless the hides were thrown upside down by the pegs inside. There was no provision for that in the invention, but it might be that the very higgledy-piggledyness of the process increased its effect.

At this stage the further cross-examination was adjourned until Thursday.

Thursday, January 15th.

On the further hearing of this action being resumed,

Mr. MOULTON, Q.C., said he did not desire to cross-examine Prof. Crookes further, as he understood there would be other witnesses who would speak to the electrical part of the invention.

Digitized by Google

In re-examination by Mr. Farwell, Prof. CROOKES said he considered it made no difference in the process whether the hides were turned in a horizontal or vertical barrel.

Prof. SILVANUS THOMPSON stated that he had considered the specification of Messrs. Worms and Balé from a scientific point of view. He was acquainted with the length of time occupied in tanning before Messrs. Worms and Balé's process. Roughly, the reduction in the time the operation took now and formerly varied from four to 14 months under the old process down to from two to five days in the new process. The new process was a complete departure. Drums for the purpose of rotating skins in the tanning liquor were perfectly well known things, and he had seen vats in the pits in tan yards moved round in the tanning liquor. He had seen the defendant's apparatus at work, and the model produced was substantially correct. There was practically no difference between the motion of the axes in Messrs. Worms and Balé's barrel and that in the infringement. He did not know of any difference between the two as to the effect of the tanning liquor on the hides, and there was also no difference between the electrical operation in the one case and the other. He had experimented upon the electrical part of the invention. There was no difference in the electrical action of the defendants' as compared with the plaintiffs' process. He did not find anything in plaintiffs' specification for producing rapid tanning except electricity and motion.

In cross-examination by Mr. MOULTON, Q.C., witness said that in a general way he knew a good deal about tanning. For many years in tanning it had been known to be important to keep up the circulation of the tanning liquor. This was not only well known, but plant had been designed to facilitate it. A process was used in America known as the rocking process, in which hides were rocked in the liquor upon frames. He had never heard of skins being placed on a frame which was run upon wheels from end to end of a trough of tanning liquor: it was ingenious, but he never heard of it before. As each new plant was introduced, of course special advantages were claimed for it. The one essential effect of using the rotatory drum was to produce suppleness in the hides. According to the French specifications, electricity was well known as aiding the rapidity of tanning. He only knew in a general way that the application of electricity increased the speed of tanning. In 1884 he was shown by Mr. Goulard skins that he had tanned in pits by the aid of electricity, and that the process of tanning, he was told, occupied a period of two months. So far as he knew, it might take a month for the defendant's apparatus to produce sole leather. Assuming it took that period, there was a difference between the defendant's and plaintiffs' apparatus, the advantage being with the plaintiffs. He could not indicate the cause, not being acquainted with all the circumstances and details of the operation. He could not say whether it arose from not having the advantage of the rotating drum or not, but it was certainly not entirely a question of plant. The strongest part of the current was at that point immediately under the axle. He had been to see the defendant's apparatus at work at the Grange Works, Bermondsey. The apparatus was rotating, but there were no hides in the vats, and no electricity was being used. He saw, however, how the electricity was applied. He saw two apparatus—one being a round drum and the other a square tank, and in the latter the process was to move the hides to and fro on a frame, and to apply electricity to the tank. There was nothing special about the way in which electricity was sent through the liquor. The similarity between the defendant's and plaintiffs' process was that the motion was rotatory in each case.

In re-examination by Mr. FARWELL, witness said he never heard of an apparatus like the defendant's square model being used, and knew of no results produced by it. The strength and quantity of tanning liquor had a great deal to do in producing suppleness in hides.

Questioned by his LORDSHIP, witness said that he could not say whether the defendant's model would come within the term rotary drum, but for the purpose of producing motion, he should certainly call it a rotating drum. As to the square model there was no rotating motion whatever of a relative kind.

Prof. GEO. FORBES: He agreed thoroughly with all that gentleman's statements on the electrical and mechanical parts of the question, but he had not the same experience of tanning operations.

Cross-examined by Mr. MOULTON, witness said that his remark applied to the cross-examination as well as the examination-in-chief. The mechanical and electrical effect in tanning of the old rotating drum and the effect of rotation in a cage like the one produced was identical. He heard Prof. Thompson say that the rotating drum produced a suppling effect, but there was not much, if anything, like that in the rotation in the vat. That being an important matter, the effect produced by the two methods was not identical.

Mr. JAMES SWINBURNE likewise agreed with the evidence of Prof. Thompson. He understood that when it was wanted to make the skins supple on a rotating drum, a large number of skins was used, and a comparatively small quantity of liquor, so that the skins were turned about a good deal. For the tanning of heavy skins, few skins were used in comparison with the liquor, so that the mechanical action of the skins was less. He did not think the strength of the liquor was as important as the relative quantity of skins and liquor; the more punching there was, the more suppleness was produced. Electricity helped the liquor to penetrate the skins, and when the liquor penetrated a fresh supply of it was taken in.

Re-examined by Mr. FARWELL: The simultaneity of the mechanical motion and electricity was the whole gist of the invention; without this the efficacy of the process would be less, because the liquid in the immediate neighbourhood of the skins would be used up. This simultaneity was found in the defendant's process as well as in the plaintiffs' process. He considered this to be a mechanical equivalent of the plaintiffs' motion, but an inferior one.

In cross-examination by Mr. MOULTON, Q.C., witness said he was not sure how far rotation was important, and he did not think their knowledge was sufficient to enable electricians to say how far it was important to reverse the current of electricity. In order that hides should not remain in the tanks stationary for too long a period it was formerly the custom to have them taken out and put back again. This was done for the express purpose of freshening the liquid in contact with the hides. It was well known that the application of electricity increased the rapidity of absorption. The freshening of the liquid was more important the more rapidly there was absorption, and that was where the importance of the invention came in. He had never been to a tan-yard before he was employed in this case. A rotating drum did more than freshen up the liquid, it acted upon the hides in producing suppleness. The drum being enclosed would produce heat, but he could not say what effect that would have on the tanning, though most chemical actions went on better at a slightly higher temperature. The defendant's process did not bind the skins together and churn them up as in the case of the revolving drum. The defendant's process by the square model was on the broad question of electricity and motion a practical equivalent of the plaintiffs', but there were differences in the results that might be important.

Mr. JOHN THOMAS BLACKMORE, a practical tanner of 30 years' experience, said that at one time he was a Director of the plaintiff Company, but he was no longer so.

Mr. MOULTON: Resigned for purposes of the trial, we know. (Laughter.)

Proceeding, Mr. BLACKMORE said that he had used the plaintiffs' process some months before the Company was brought out, and found that it was an advantageous system, as it enabled the operation of tanning to be completed so rapidly. He had not tried the defendant's process, but had seen the models at defendant's premises when he acted as agent to Messrs. Worms and Balé. Apart from the application of electricity, he did not consider the defendant's process of any use, as it took too long to complete the operation of tanning.

In cross-examination, witness said that defendant's process would take a period of thirty days to complete the operation of tanning, and that being so, the cost of steam-power and labour would be ruinous. He considered the reason for that was that the apparatus in each of defendant's processes was open at the top. Without the application of electricity the plaintiffs' process, being enclosed, would tan more rapidly than the defendant's.

This closed the evidence in support of the plaintiffs' case, and

Mr. FARWELL, on behalf of the plaintiffs, summed up the evidence, and submitted that the patent of the plaintiffs was novel, important, and useful, and that the plaintiff Company was entitled to the injunction sought for, to restrain the defendant from infringing the invention, the patent rights of which belonged to the plaintiff Company.

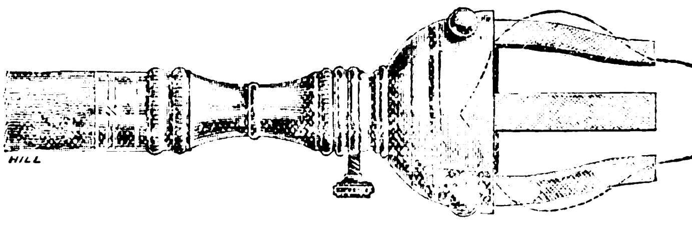
The Court then adjourned for lunch.

## TRADE NOTES AND NOTICES.

*[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]*

FIRE.—A disastrous fire broke out on Friday afternoon at the show-rooms of Messrs. Richard Evered and Co. (Limited), electrolier manufacturers, at 49 and 50, Holborn-viaduct, E.C., the upper floors being badly damaged by fire and water, and the rest of the premises by water. Messrs. Evered and Co. state that, notwithstanding the fire, they are still able to meet any demands that may be made upon them for the exhibition of their specialities.

INCANDESCENT LAMP CHANGER.—Messrs. Edmundsons, of 19, Great George-street, Westminster, are introducing a very useful device for removing incandescent lamps which are placed far out of reach upon ceilings, &c. By means of the lamp changer this can be effected in a few moments, and without the use of long steps, which are usually necessary to reach the lamps. The apparatus consists of a spring socket, as illustrated, mounted on a ten-foot rod, which



for convenience is made in three joints. The socket grips the lamp firmly, and enables it to be easily removed from or replaced into the usual bayonet joint or screw-holders.

THE GENERAL ELECTRIC COMPANY.—The eighth edition of this Company's electric bells and accessories catalogue is just issued, and consists of 76 well arranged and fully illustrated pages; descriptions and prices are given of various classes of electric bells, bell sets, watch and clock alarms, indicators, bell show boards, pushes, pulleys, &c., bell switches, fire alarms, heat indicators, exploders, and fusers, batteries, insulators, &c., &c. In addition

Digitized by Google

to a number of useful electrical accessories at the end of the catalogue, some notes of the application of electricity, and instructions for fixing bells, &c., by diagrams are given. The General Electric Company's new catalogue of telephone accessories is promised shortly.

THE MANCHESTER EDISON-SWAN COMPANY.—This Company has experienced considerable increase in its business during 1890, some 33,469 incandescent lamps having been supplied by them for the Lancashire district. At the commencement of the year they found it necessary to take additional premises in Little John-street, Manchester, on account of the increase in the manufacturing branch of their business. This, however, now proves to be inadequate, and it has been decided to move their works further out of the city, where a well appointed and commodious factory will shortly be built.

THE WOODHOUSE ELECTRIC SUPPLY COMPANY OF GREAT BRITAIN (LIMITED).—We are notified that Messrs. Woodhouse and Rawson United (Limited) have taken over the business of this Company, excepting so far as the supply of incandescent lamps made under licence from the Brush Electric Light Company is concerned. This part of the business will continue to be carried on by the Supply Company as before.

MESSRS. COX AND CO.—This firm of manufacturing electricians have opened new premises at Fetter-lane, opposite the Record Office, where they will keep a large stock of apparatus and materials for all scientific work. They have also issued illustrated lists of each department, and that dealing with electrical apparatus, which gives details of telephone facts, &c., should be specially useful.

MESSRS. RICHARD FRÈRES.—This firm is about to open, at 43, London Wall, E.C., a branch office and show-room for the exhibition of their specialities in self-recording scientific instruments. Mr. J. A. Berly will be entrusted with the management.

REMOVAL NOTICE. — The Empire Telephone Company has changed its offices from 60, to 171, Queen Victoria-street, E.C.

VOLTA ELECTRICAL COMPANY (LIMITED) (IN LIQUIDATION).—We understand that this Company has been finally wound up, and that a dividend will shortly be paid to the shareholders.

PORTSMOUTH AND SOUTH HANTS ELECTRICITY SUPPLY COMPANY (LIMITED) (IN LIQUIDATION).—Claims are to be sent in to the liquidator, Mr. W. Edmonds, C.A., Portsea, by February 14th.

COMMERCIAL CABLES COMPANY.—We have received a handsomely got-up calendar issued by this Company, which is certainly equal to any previously issued by the Company, and will be found very useful.

## COMPANIES' MEETINGS & REPORTS.

### The Eastern Telegraph Company (Limited).

The thirty-seventh half-yearly ordinary general meeting of the Eastern Telegraph Company (Limited) was held yesterday, at Winchester House, 50, Old Broad-street, E.C.; Sir John Pender, K.C.M.G., presiding.

The SECRETARY (Mr. Geo. Draper) read the notice convening the meeting, and the minutes of the previous meeting, which were confirmed by the present meeting, and signed by the Chairman as correctly entered.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said that before entering upon the business of the day he might fairly congratulate them on the year that was passed, and express a hope that the one they had just entered upon would be as prosperous for the Company. Their revenue from all sources for the half-year ended September, 1890, amounted to £352,873, as against £351,014 in the corresponding period of the previous year, showing an increase of £1,859. Analysing this revenue, they would find a falling off in their receipts from telegrams exchanged with South Africa of over £5,000. In addition to this, the dividend that they had had on their investment in the South African Company was £5,900 less than in the corresponding six months, so that they ought to put down a loss of £11,000, as attributable to the collapse of speculation in gold mining and diamond shares in South Africa. Their Egyptian, Greek, and Turkish traffic also showed a decline of some £1,500, but this decrease was made up by a growth of over £12,000 in their Indian, trans-Indian, and Spanish traffic, and by increased dividends on their other investments of £2,000. For the six months they showed a gross increase of £1,859. The total working expenses for the half year to September, 1890, amounted to £91,723, as against £87,730, or an increase of £3,993. The general expenses in London were £8,502, against £8,410, or an increase of £92. The working expenses at stations amounted to £68,435, against £64,712, or an increase of £3,723, the principal item being £2,657 in the salaries of their foreign staff. A number of their more advanced probationers were transferred to the staff at Porthcurno, Gibraltar, Malta, and Zante in connection with the full working of the triplicate cable, and in the increase in the number of messages carried. There was also an increase of £639 in repairs to stations, buildings, &c., the most important being at Alexandria, where rather extensive alterations and improvements were being carried out. The amount written off for depreciation of cable stock was £802 more than in the corresponding period, owing to their having a larger stock of spare cable. The amount carried to the Maintenance Ships' Reserved Fund was only £2,500, as against £5,000 in the previous half-year, the other portion having been contributed by those telegraph companies who had hired their ships during the half-year. The expenses in connection with the Paris Telegraph Conference, which appeared in the revenue account this time, amounting to £981, was an exceptional item, but a very necessary one, and he thought he might safely say that full value had been received for this expenditure. Expences attending repairs and renewals of cables amounted to £31,477, against £49,634, or a decrease of £18,157. Full details of the expenses of the ships, &c., and value of cable used would be found on reference to abstract "C" of the accounts. The amount of cable used in repairs during the half-year was exceptionally small, and their ships had been several times employed in cable laying and repairing work for other companies, the credits derived from this source having been applied in reduction of the ship's expenses, &c. The summary of the half-year's revenue account was as follows:—The increase in gross revenue and amount brought forward from last half-year was £3,369, while the decrease in the total expenses was £18,678. They were, therefore, after providing for all expenses and interest charges against revenue, able to pay the usual interim dividend at the rate of 5 per cent. per annum, and to carry forward to next half-year's account £78,195, against £61,151, or £17,044 more than in the corresponding period of 1889. He thought that this condensed statement of their affairs must be a very satisfactory one to them all. They had not increased their capital to any extent, but still they had laid down cables that amounted to nearly a million sterling, which they had taken from their reserves; and although they did not receive a very large dividend, the shareholders had got behind them in consequence a great deal of strength, as was apparent from the value of the shares in the Market. They had doubled, trebled, and quadrupled many of the cables in their system, and had been carrying out the policy, which they had always adopted, of being ahead of the requirements of the public. He had, on previous occasions, indicated that in this lay their strength, and when they found that a new departure was going to take place in the Australian Colonies, by way of an endeavour on their part—which was very strongly supported by the Company—to reduce the rate from 8s. to 4s. a word, they felt that if that was to be successful, they must practically double the volume of traffic over their system. That traffic had to come largely over the Eastern Company's system, and consequently it would never have done for them to be behind in their arrangements to meet it. Consequently they were now about to complete the laying of a third cable in the Red Sea which would enable them effectively to deal with that large increase of traffic from Australia. He concluded by moving the adoption of the report and accounts.

The Marquis of TWEEDDALE seconded the motion, which was unanimously agreed to without discussion.

The retiring Directors, Sir John Pender and the Marquis of Tweeddale, were afterwards unanimously re-elected to their seats at the Board.

The auditors, Messrs. Henry Dever and Welton, Jones and Co. were also reappointed, and a vote of thanks to the Chairman and directors having been passed, the proceedings terminated.

[*A full report of this meeting will appear in our next week's issue.*]

### Woodhouse and Rawson United (Limited).

Sir Rawson W. Rawson presided, on the 9th inst., at Winchester House, Old Broad-street, over an extraordinary general meeting of the shareholders in this Company, convened to consider two resolutions: 1, for authorising the Directors to enter into an arrangement with the liquidators of Woodhouse and Rawson (Limited) for repaying the sum of £75,000 deposited by them with the Company until July 1, 1892; and 2, for increasing the capital of the Company by the issue of 40,000 new shares of £5 each.

The SECRETARY (Mr. G. Worrall) having read the advertisement convening the meeting,

The CHAIRMAN said:—Gentlemen, about a year ago I had the honour of occupying this chair at our statutory meeting, and of expressing to you my confidence that the Company would realise fully the expectations of its promoters, the promises of its prospectus, and the hopes of its shareholders, and I am happy on this occasion to have the opportunity of repeating the confidence of the Board that the success which has hitherto attended the Company will continue to be maintained. It will be in your recollection that Lord Aberdare, our late Chairman, whose retirement from the Board we greatly regret, stated his opinion very confidently that the capital of the Company was insufficient for the opportunities it had of realising large profits from excellent and sound undertakings. His colleagues were of the same opinion, and were prepared at an earlier period than the present to address the shareholders upon that subject, if it had not been for the financial crisis which has stopped anything of the kind for some weeks past, and we have taken the earliest opportunity that we consider advisable to present our views to you, and ask your sanction to what we propose to carry out. There are two objects in the resolutions that have been circulated, and which you have had the opportunity of examining. The first is to enter into such arrangements as we may think advisable in the interests of this Company with the liquidators of Woodhouse and Rawson (Limited) for repaying the sum of £75,000, which was deposited by them with us as a guarantee that for three years the shareholders of this Company should be secured 8 per cent. on their Preference shares, and 15 per cent. on their ordinary shares. You will have seen in our balance-sheet for the first year that the profits of that year, after paying those rates of dividend to our shareholders, left a surplus of £41,000—equal to about a year and a-half of our annual payment at those rates to our shareholders. Now a year and a-half has already

Digitized by Google

elapsed of the three years for which the guarantee fund was left in our hands, and it is time that we should consider how that sum is to be repaid. Therefore, we consider that it is convenient when we are asking you to increase our capital for general working purposes to propose to you at the same time an arrangement for repaying the limited company this loan. I had hoped that we might have been able to inform you to-day that the terms were settled, but they have not been arranged up to the present moment. We feel confident that the security of our shareholders is perfect for the three guaranteed years. Already one year has elapsed, and we have paid our shareholders at the rates that we undertook—namely, 8 and 15 per cent.; another half-year has elapsed, and our profits have been, I may venture to say, not less than last year. Our expectations of the coming six months are no less favourable. We shall, therefore, at the end of the second year have another surplus to add to the £41,000 wherewith to pay our shareholders at the end of the third year. We are not pledged beyond the third year, but our hopes certainly extend beyond that period, and we trust that at the end of three years we shall not be in a worse position than we are now to satisfy our shareholders with large and abundant profits. The second point is that the capital of the Company be increased from the present amount to £550,000 by the creation of additional shares. When this Company was brought out the working capital for which we asked was decidedly moderate. We were satisfied that we should be able to show such a rate of profit as would justify us in coming before the shareholders, and saying, "You see what we are capable of earning. If we have a larger capital we shall be able not only to continue this rate, but to improve upon it, and we believe that our shareholders will then find sufficient reason for confidence in the Board to meet their appeal, and to furnish them with further capital." Well, since that time, which is now about 18 months ago, things have considerably changed. Experience has shown us that our capital is insufficient, as our business has largely increased. I yesterday had put into my hands the earnings of our supply department. The second six months were 50 per cent. over the first six months; the third six months were 30 per cent. over the second six months; and this in the supply business alone, where we must hold in our hands a large and very valuable stock of electrical goods to meet the demands of our customers, and moreover must have large outstanding accounts, with several thousand customers, swallowing up our available working capital. In the same way we have already stated to you that we have increased our business by the purchase of one very important and very extensive business to enable us to hold, as we believe, our prominent position amongst the electrical companies of England. We should be sorry to drop back instead of progressing in our position, and in order to secure it, and to be independent of other people, we find it necessary that we should manufacture a number of the more important articles required by our customers so as to be ready to meet their wants without delay, and without the difficulty of procuring the articles from other people. As regards the Debentures, our Articles of Association empower us to increase the issue to the extent of £250,000. Inasmuch as the value of money, independently of the recent financial crisis, has decidedly lowered, and the action of the Chancellor of the Exchequer with regard to the conversion of Consols last year has given us an indication of the probable future value of money, we consider that the 6 per cent. interest payable to our Debenture holders is excessive, and it is therefore our intention to recal those Debentures, giving the holders of them the profit that we promised them at the time of their issue, and issuing a larger sum at 5 per cent., probably to the extent of £200,000 instead of £100,000. That will be a profitable arrangement for the Company and for the ordinary shareholders, for there will remain a larger sum available for distribution to them. As regards the Debenture holders, they have a largely-increased security, having the advantage of all the purchases of real property and factories that we have made; and in other respects their position will be improved. As regards the question of the issue of new shares, you are aware that the shares already issued have recently fallen in value. Your directors have not been at all frightened by that, inasmuch as 15 per cent., safely earned and likely to be continuously earned, ought to place the shares considerably above par. We have had several difficulties to contend against. We have had the difficulty of the delay in the settlement of the affairs of Woodhouse and Rawson (Limited), for which we are in no way responsible, and for which the liquidators, as far as we know, have not been responsible. The public do not understand the difference between Woodhouse and Rawson (Limited), and Woodhouse and Rawson United (Limited). That difficulty, happily, is at an end. Another difficulty we have had is in connection with getting a quotation for our shares. The Committee of the Stock Exchange is exceedingly particular. One difficulty that we had was in consequence of our issuing 100 shares in payment to a patentee from whom we had bought a patent. That happened not to be included in the list. They noticed it, and said these were vendors' shares. That caused weeks of delay; and so in the same way from time to time it has been delayed. I am happy to say, however, that there remains only one affidavit now to be completed in order to obtain our settlement. That affidavit we count upon receiving next week. The Managing Director reminds me that one of our difficulties has been in taking over so many companies and businesses. There has been a remarkable and unusual complication in clearing the whole of the transactions to the satisfaction of the Stock Exchange. These circumstances have combined to lower the value of our shares beyond their proper value, but we feel confident that when our shareholders and the public find that the profits we made last year are not accidental, and not casual, but will be maintained this year, and have every apparent prospect of continuing during the third year—we cannot look further than that—that the public will have restored confidence in our shares, and that the shares will reach their proper value. There are three good reasons for our not calling up our uncalled capital. The first is, that our ordinary shareholders, some of them at all events, were led to expect that it was not our intention to do so unless it was absolutely necessary. Another cause has been that we thought it right to keep this capital in reserve, for the purpose of meeting the repayment of the loan to the limited company. The third reason is that it is exceedingly desirable in a company carrying on a business of this kind to have a reserve fund upon which, when opportunities of useful extension present themselves, they should be able to borrow for temporary purposes, instead of keeping a large balance at the bankers yielding the small rate of interest that money now fetches. I have the satisfaction of drawing your attention to the success which has attended the Company, both in the matter of the Elmore shares, and of the International Okonite shares. Every day confirms the truth of the original statements made with regard to the value of the Elmore process and the two companies that have been issued for foreign countries, which are only a prelude to the arrangements for the sale of the patent in other countries. The French Company will hold their meeting this afternoon, and I have reason to know that statements will be laid before the shareholders of that company, which will contain the most satisfactory assurances of the confidence that the French members of the Board have that the process will be even more profitable than has been held out hitherto to the shareholders of the company. With regard to the other company, the International Okonite Company, the certificate of the accountants, Messrs. Price, Waterhouse and Company, shows that our expectations of the earnings for the six months of last year, from January to July, have been exceeded. The Directors of that company have announced their intention of paying an interim dividend at the rate of 10 per cent. upon the working of the last six months; and this, it must be borne in mind, has been before the Manchester branch has been able to erect their works and commence operations under the Okonite patent in England. Consequently the success of the International Okonite Company, as far as profits are concerned, is substantiated to the fullest. These are companies in which we have been interested, and they will give you an indication of the class of enterprise that we desire to promote—not untried companies, or chance patents, but patents and processes that we have the opportunity of testing with our numerous staff, scientific and financial, and with our variety of factories. We can therefore see that in taking up these things we do not take up anything haphazard. The method of our taking them up secures us from any risks beyond that of the expense of launching the companies, so that our shareholders need not be afraid that the Directors are likely to embark in any rash undertakings that are calculated at all to risk the property and the capital of the shareholders. With regard to our own factory, you are aware that we have leased one of our buildings at Kensington to the Kensington Stores, and we have therefore built a new block for ourselves nearly double the size of the original one. We hope, by the end of February, that this will be at work, and we have a number of new machines ready to manufacture as soon as we are able to get into the new premises. Our profit from that branch of the business is likely for the future to be very much larger than it has hitherto been. I think I need not detain you longer except to say that, as far as we can judge, our future prospects are very bright, and as our promises have been realised during the past year, we hope that you will give us your confidence, and believe that we would not make a promise for the coming year if we were not satisfied that it would be substantiated. We expect that the interim dividend for the past six months will be declared in a very short time. He concluded by moving the first resolution as follows:—

*"That the Directors be authorised to enter into such arrangement as they shall think advisable with the Liquidators of Woodhouse and Rawson (Limited) for the immediate or early repayment to such Liquidators of the sum of £75,000, or any part thereof, deposited with the Company on the terms that it should be retained till the 1st of July, 1892, as a Dividend Guarantee Fund."*

The Right Hon. Sir E. THORNTON, G.C.B., seconded the motion.

In the course of the discussion which followed several speakers addressed the meeting. Objection was taken to the proposal to repay the loan of £75,000, it being contended that much of the profits that had hitherto been made had been in connection with the promotion of companies, and not from legitimate trading. It was further pointed out that interest would have to be paid on the money, which was obtained to repay the loan, whereas on the latter the Company paid no interest. Disappointment was also expressed at the delay in the Company's securing a quotation for the shares on the Stock Exchange. Some of the speakers thought that the repayment of the loan might be a judicious financial operation for the benefit of the Company. The general feeling of the speakers was that the present would be an inopportune time for issuing new shares, the existing shares being at a discount.

The MANAGING DIRECTOR (Mr. F. L. Rawson) at the close of the discussion said: The Chairman has asked me to answer the various questions that have been asked, and also to amplify anything in his speech that I might consider advisable to mention to the shareholders. I should like to call attention to the fact that the proposed new capital is an additional security for the Debenture holders justifying the increase of the Debentures to £200,000, and the reduction to 5 per cent.; secondly, that the depreciation that has taken place in the market value of our shares is very largely due, not only to the financial position of the country—for if you take almost any of the industrial securities you will find that they have fallen from 10 to 20 per cent.—but also to the fact that during the last two months we have been distributing the shares of the companies whose properties we purchased under the agreements made. We gave the shares to the liquidators of those companies some time ago, but they were not able to distribute them until quite recently, and hence during the past fortnight or month there has been about £80,000 of capital put upon the market, and large numbers of shares have been obliged to be put upon the market at the

Digitized by Google

same time. During the past few days, however, the shares have steadily risen. I bought some myself yesterday, and had to pay a good deal more than I expected. The name of Mr. Baker, our works manager, has been mentioned as having sold shares. I was rather surprised when I heard Mr. Baker was selling, and I took an opportunity of speaking to him on the subject. The explanation is this: It seems that Mr. Baker was paid altogether in preference shares when we purchased his interest, and he had to realise a large number of them in order to settle his own arrangements. I may mention, however, that Mr. Baker has ever since, from time to time, been steadily buying ordinary shares. The same remarks apply to myself. I have taken up some £28,000 of shares in the last six months, and paid 5s. premium on them, and I do not think you could have any better proof than that of my belief in the future of this undertaking. The prospects of the Company are decidedly good. We may have been thought speculative in purchasing so many as four new businesses in so short a time as 18 months, but we wanted to put ourselves in the position of being able to manufacture, creditably to ourselves and profitably to our clients, every class of electrical goods; and this we are now able to do—with the exception of cables and wires which are a special manufacture by themselves—and I may add that the businesses we have taken over have turned out very well. In one of them, about which we were a little doubtful, we have received an important commission from the Government, and I hope it will result very profitably to our Company. As regards new companies, we have been quite different from ordinary company promoters. We have been connected with very few companies; indeed, during the 18 months of our existence we have only been connected with three, counting the Elmore as one. As a rule, we are associated with any new enterprise we take up for some 18 months or two years before they come out as companies. We gradually work at them, and help to build them up, so that we have a long experience of them, and know what they are capable of. At the meeting last year it was mentioned that we had three new inventions in hand. I am glad to say that all of them have turned out very satisfactorily. One is completed, and we are now commencing manufacturing on a large scale ourselves. If it outgrows our capacity we shall turn it into a separate company. We have another new electrical invention, which we have now commenced to carefully test. The demand for electricity, both for lighting and motive power, has increased so much that the position is now very different to what it was 18 months ago. The electric light, as the Americans say, has now come to stay. With regard to the remarks made by one speaker, I would like to draw attention to the fact that we have the power of paying the liquidators this £75,000 in cash or debentures, and naturally we shall pay them in what is most advantageous to the Company. If we give them Five per Cent. Debentures it only adds a sum of £3,750 per annum to our annual expenses, which is very small out of a margin of profit of £41,000. Suppose we get a discount of 10 per cent., in that case we should have a profit there of about £5,000, or about a year and a-half's interest. Then, with regard to the issue of the new shares, the Directors have only asked for the power to issue them, and they will do so when a favourable opportunity presents itself. If the ordinary shares are only half paid up we shall have £150,000 of share capital, whereas we shall have the benefit of £100,000 of Debentures, besides reducing the rate of interest to 5 per cent. The uncalled capital is a valuable security for those Debenture holders; and we must have a proper proportion of ordinary and Preference shares and Debentures. The Chairman has told you that we are about to pay the interim dividend; we have made in six months more than enough to pay the whole year's dividend at 15 per cent. The first thing I look to in our business is to have it safe, because our profits are so large now, and the electrical business has increased to so great an extent that we need not go into speculative things. I do not think there is a single business that we have gone into during the last year and a-half that has practically involved us in a liability of even £10,000. We consider it right to set a portion of our profits aside for the repayment of the guarantee fund. At the date of the last balance-sheet we had lent Woodhouse and Rawson (Limited) £39,000, and we also put certain shares aside as security; but since the balance-sheet those shares have been sold, and they fetched more than the price we put them down at. We have re-invested part of that money, and that is set aside for the repayment of the amount. We do not care to invest sums of that kind in Consols; we take the class of security that does us good and helps our business. With regard to the notice of meeting being rather short, Mr. Horsfield is quite correct in that view, living as he does in Manchester; but it must be remembered that changes of a financial character may occur so quickly, thus affecting the market, that no time can be lost in a matter like this. I am, however, sure the Directors will not object to our giving longer notice in future when possible. With regard to the time of issue of the new shares, it is ridiculous to imagine our shares being so low when such large profits are being made, and where the surplus profits are so good. The price, therefore, must rise, more especially after a meeting such as this, when you have heard what a satisfactory position the Company is in. I think the manufacturing profits will be considerably larger this year than last—£10,000 or £12,000 larger. With regard to our new Company work, you will be glad to hear that now a very different class of business is being offered us. We have a tremendous amount of work offered in connection with new companies, with which there is practically no risk to us at all, but which we do not accept. In the late Elmore companies, for instance, we did not involve ourselves in one penny risk; we had not even to pay any preliminary expenses or anything of the kind. We made arrangements whereby all others did this.

The CHAIRMAN then put the resolution, and it was carried *nem. con.* Continuing, he proposed the second resolution, as follows:—

"*That the capital of the Company be increased to* £550,000 *by the creation of* 40,000 *new shares of* £5 *each, of which* 20,000 *shares shall be Preference shares, which shall be entitled to the same preferential dividend and rights, other than the benefit of the dividend guarantee fund, and shall be subject to the same conditions as and rank for all purposes* pari passu *with the existing issue of* 30,000 *Preference shares of* £5 *each of the Company, the remaining* 20,000 *shares shall be ordinary shares, and shall be entitled to the same dividends and rights, other than the benefit of the dividend guarantee fund, and shall be subject to the same conditions as, and rank for all purposes* pari passu *with, the existing* 40,000 *ordinary shares of the Company.*"

He reminded the shareholders that the Directors were as much interested in this matter as the shareholders were—indeed personally more interested, as their credit was engaged. They would, therefore, certainly not take any action that was likely to injure the welfare of the Company. All that they asked for was permission to issue the new share capital when the time presented itself for their doing so. They believed and hoped that there would be, perhaps, a sudden revulsion of feeling, when they might go to their shareholders and to the public with great success.

Mr. PHILIP RAWSON seconded the motion, which was also adopted.

Mr. CHAPMAN then proposed a vote of thanks to the Chairman and Directors.

Mr. HOSTER seconded the resolution, which was carried unanimously, and the meeting then separated.

## Elmore's French Patent Copper Depositing Company (Limited).

The first general meeting of this Company (being the statutory meeting required to be held within four months after the registration of the Company) was held at Cannon-street Hotel, on the 9th inst., under the presidency of Sir Richard Meade, K.C.S.I.

The SECRETARY (Mr. J. Shurmer) having read the advertisement convening the meeting,

The CHAIRMAN said: Gentlemen, all present are doubtless aware that this is only a statutory meeting of the Company, and not for the transaction of business. We propose, however, to ask the meeting to sanction certain alterations in the Articles of Association, of which due intimation is given in the notice convening the meeting, which are required by the Committee of the Stock Exchange. I have stated that we are not here to-day for the transaction of business, but we are glad to have the opportunity of meeting our fellow-shareholders, and of informing them of what has been done since its formation to carry out the objects of the Company. I have first to state that the 66,750 shares offered to the public were applied for about four times over, and that a full allotment was made among some 2,000 applicants. The sums due on allotment have, with a small exception, been all paid up, and those still outstanding on the first and final calls are in course of adjustment. The Stock Exchange Committee has granted a settlement for our shares, and provided this meeting passes the alterations in the Articles of Association, of which notice has been given, there will be an official quotation of our shares on the London Stock Exchange at a very early date. Steps are also being taken to introduce our shares upon the Paris Bourse, which will, no doubt, be successful, and thus lead to an important extension in the dealings in our shares.

The first question your Directors had to deal with was that of the general management of the Company's manufactories and business in France, and they congratulate the shareholders on their having been able to secure the very valuable services of M. Eugène Secrétan as the Company's General Manager there. M. Secrétan was formerly manager of the largest copper manufacturing industry in the world, and your Directors are confident, from all they have learned and know of him, that in placing him at the head of the Company's affairs in France they have taken the most important step that was possible towards securing the complete and early success of the business of the Company in that country. M. Secrétan was, it is understood, convinced of the merits of the Elmore process when it was exhibited in Paris in 1889, and before entering the service of the Company he visited the works of the English Company at Leeds, accompanied by several colleagues, and his assurances to your Board, after making that visit, of his entire confidence in the future success of our Company were most emphatic and satisfactory. As stated in the prospectus, your Directors had secured for the Company land at Bellegarde, near the Swiss frontier, suitable for a site for the works, with water available as a motive power, but M. Secrétan was so satisfied of the vast importance of establishing a manufactory, and commencing business at first in the north of France, that, after much anxious consideration, we accepted his recommendation on this point, and decided to concentrate our attention and efforts on the establishment of works there, in the first instance, on a sufficiently large scale to admit of a more considerable out-turn of manufactured goods than was originally contemplated. M. Secrétan gave us the strongest assurances that he would be able to dispose of all the goods that would be thus turned out, and he was accordingly authorised to take the necessary steps for securing a convenient and suitable site, for the preparation of plans and estimates of the buildings that would be required, and for ordering the engines, machinery, and plant needed to stock the works. These arrangements he has carried out with characteristic energy, and we are able to inform this meeting that an excellent and convenient site, of ample extent, has been obtained by him on very advantageous terms, at Dives, near Havre; that the plans and estimates for the buildings to be erected thereon have been approved and sanctioned by the Board, and that the engines, machinery, and plant have been ordered from the best manufacturers of such articles in France. The winter season will, of course, delay the progress of the buildings, but M. Secrétan states that the works will be in operation by July 1st next. M. Secrétan, who is present here to-day, will address the meeting, and as he does not speak English, an English version of his remarks will be afterwards read. I may mention

Digitized by Google

that he has secured the assistance of a committee of experts in Paris, whose aid will be most valuable in the work that lays before him.

I will now refer to the financial aspect of the more extended operations your Directors have authorised. The prospectus provided for a working capital of £50,000, which, it was thought, would be quite sufficient for starting the works successfully on a moderate scale. But it was at once apparent that the adoption of M. Secrétan's proposals would necessitate a large increase to this amount, and, after much consideration, we decided to avail ourselves of an offer from the parent Company (Elmore's Foreign and Colonial Company, Limited) to lend to us for this purpose £50,000, at 6 per cent. per annum, for three years. The shareholders were informed of the circumstances of this arrangement by a circular issued to them on October 29th last. I have only to add that we are satisfied that the course we have thus taken was the best that it was in our power to adopt in the interests of the Company. The measures now laid before the meeting will enable the Company to retain in its own hands—instead of disposing of the same to a sub-company, as was intended—the exclusive licence to make copper wire in France by the Elmore process. The value of our shares should be largely increased by such retention, as the profits from the manufacture of wire will by-and-by be very considerable. The patents which we have purchased have been duly transferred to us, and we have every assurance that the same are perfectly good and valid. The Company obtains, free of charge, all improvements worked out from time to time by the Elmore English Company in this country, and I may mention, in this connection, that one additional patent on this account has already been taken out by us in France. It only remains for me to say that the Board has the fullest confidence in the future success and prosperity of the Company. I or my colleagues will be happy to answer any questions that may be put to us before I propose the resolution for the alterations in our Articles of Association. I have the pleasure, before sitting down, to introduce M. Secretan to the meeting.

Dr. HETLEY inquired whether the extra £50,000 capital, to which the Chairman had referred as having been raised, was in debentures or preference capital.

The CHAIRMAN: I venture to suggest that any remarks may be deferred until after M. Secretan's address.

Dr. HETLEY: Certainly.

M. SECRETAN then addressed the meeting in French, his remarks being subsequently read to the meeting in English by the Secretary, as follows:—I am very sorry I cannot express myself in English, and I trust some member of the Board will kindly translate the few words I ask permission to address to you.

Gentlemen, the Board of your Company has expressed a wish that I should be present at this meeting. It is with great satisfaction that I have complied with that request; because, on the one hand, it permits me to thank your Directors publicly for the honour they have conferred upon me by appointing me general manager of your Company in France; and, on the other hand, I thought you would be glad to hear a few words from me on the present and future position of your Company. The extended and careful investigations and trials that have been made up to the present time have convinced me and my most trustworthy and competent advisers that the Elmore process has definitely reached a practical manufacturing stage. You have the exclusive right to manufacture under this process in France, and the articles produced are of extraordinarily good quality, and the cost of production is extremely low, more so, indeed, than is stated in the prospectus. These facts being now incontestable, the time for hesitation has passed, and that for work has arrived. I have submitted to your Board plans for the erection of the first factory, and I had the good fortune to see them fully approved. Immediately after this approval I entered into arrangements with excellent contractors for the erection of the buildings, and with the most competent manufacturers for the machinery and plant. There will be no hitch in the completion of your factory, as too often happens. To avoid this I have only dealt with firms of the highest standing and the greatest experience, who are renowned for the scrupulous carrying out of their engagements. With these I have entered into definite contracts at prices which are absolutely binding, and cannot be exceeded. Under these contracts the buildings will be handed over complete at the end of next April. Engines, boilers, dynamos and plant generally will be erected, in working order, by the end of June, and on July 1st next your first works in France, constructed to produce 370 tons of copper articles per month, will commence work, and will at the end of another three months have reached their full production. I need not tell you that the sale of these articles is absolutely assured. Supported by the confidence of your board, seconded by my French Committee of Direction, and aided by a staff, of whose industry and goodwill I cannot speak too highly, I undertake, as far as I am personally concerned, to work with untiring energy, and with entire devotion to your interests. In conclusion, I can assure you, gentlemen, that you can regard the future with absolute confidence and faith in the prosperity of your Company.

The CHAIRMAN then called upon Dr. Hetley.

Dr. HETLEY said he desired to know whether the additional £50.000 of capital was in Debentures or in Preference shares. In the event of its being Debentures, he thought that it might have been offered to the shareholders.

M. LAWES asked what the profits of the Metal Company had been to which the Chairman had alluded as having been formerly managed by M. Secretan, whose address, it had appeared to him, had not contained any practical facts.

The CHAIRMAN: You cannot expect a reply to a question like that. We all know that M. Secrétan's experience has been very great in the particular business in connection with which he has now taken service with us.

Mr. LAWES, continuing, observed that in the first prospectus a point was made about the water-power by which the Elmore process was to be carried on at a very low price. It seemed to him that all this had been thrown to the winds by the change in the *locale* of the Company. It also appeared to him that before the shareholders would derive any benefit from their works every penny of the profits was hypothecated to another company. Six per cent. interest and 5 per cent. premium seemed to him to be a high price to have paid for the additional money they had required.

Mr. F. L. RAWSON stated that it was with M. Secrétan that his (the speaker's) firm, Woodhouse and Rawson, originally negotiated the sale of the Elmore patents for £750,000. The opinion of his brother, who was in France for many months, of M. Secrétan was of the highest description M. Secrétan did not pretend to be a financier, but as a metallurgist and as a manufacturer of copper, he stood *facile princeps*. When he saw that there was a chance of M. Secretan coming to the French Elmore Company, his own remark was that the future of that Company was assured.

The CHAIRMAN, in reply, said: I understood Dr. Hetley's meaning to be that the debentures ought to have been offered to the shareholders of this Company?

Dr. HETLEY said he thought they might have been; he would not say ought to have been.

The CHAIRMAN: I am informed that Elmore's Foreign and Colonial Company, who lent the £50,000 on Debentures, would be very glad to issue them to any of the shareholders of this Company who are willing to take them up. We could not enter into any "part and parcel" arrangement in this matter. The great object we had in view was to secure promptly the possession of a sufficient sum of money to enable us to start what M. Secrétan assured us was necessary for the success of the Company. We could only do that by accepting this arrangement which was offered by the parent Company to lend us the sum of £50,000 on these terms, which we consider to be fair. We came to that conclusion after very great consideration, and are perfectly confident that it was the best thing we

could have done for our Company. We had secured a site at Bellegarde with water-power, but we could not commence two manufactories at once; and the weight of evidence in favour of starting first in the North of France was so conclusive that we were compelled for the present to put Bellegarde aside. We still, however, retain our interest at Bellegarde, and when the proper time comes, and we have money sufficient to start a second factory, we propose to establish one there.

Mr. RAWSON observed that the profits of the Société des Metaux, of which M. Secrétan was formerly the manager, were last year £240,000.

The CHAIRMAN: Are there any other questions? Then I will propose the first of the resolutions for altering the Articles of Association. They are merely formal, in accordance with the requirements of the Committee of the Stock Exchange. The first resolution is as follows:—

*"That the following words be added to Article 15, at the end thereof:—'Provided that twenty-one days' notice at least shall be given of each call, and that no call shall exceed one-fourth of the nominal amount of a share, or be made payable within two months after the last preceding call was payable.'"*

Major CHARLES JONES seconded the resolution, which was carried.

On the motion of the CHAIRMAN, seconded by Mr. C. G. PHILIPS, the following resolution was also agreed to:—

*"That the following words be added to Article 44, at the end thereof:—'Provided that the Directors shall not, without the sanction of a general meeting of the Company, raise or borrow any sum of money which will make the amount raised or borrowed by the Company and then outstanding exceed one half of the subscribed capital of the Company, and so that every Debenture, Debenture Stock Certificate, Mortgage, or other charge shall be under the common seal of the Company.'"*

The CHAIRMAN afterwards proposed, and Major JONES seconded, the following resolution, which was carried unanimously:—

*"That the following words be added to Article 116, at the end thereof:—'A printed copy of such balance-sheet shall seven days previously to the meeting be sent to the members in the manner in which notices are hereinafter directed to be served.'"*

Sir RAWSON W. RAWSON then proposed, and Dr. HETLEY seconded, a vote of thanks to the Chairman, which was agreed to, and a similar compliment was paid to M. Secrétan on the motion of Mr. CALLANDER, seconded by Mr. CHIROL.

The CHAIRMAN: On the part of my colleagues and myself, I have much pleasure in thanking you for your kindness in proposing the vote of thanks, and I can only assure the shareholders that they will have the very best efforts of myself and all associated with me on this Board in making the Company a success.

The meeting then separated.

## The Direct United States Cable Company (Limited).

The following is the report of the Diectors of this Company for the six months ended December 31, 1890, to be presented at the twenty-seventh ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E.C., this day (Friday) at 2 p.m.:—

The half-year's revenue (subject to revision on decision of the case mentioned below), after deducting out-payments, amounted to £43,346 13s. 7d. against £42,356 12s. 1d. for the corresponding period of 1889, being a difference of £990 1s. 6d. in favour of the half-year under review.

The working and other expenses for the half-year with income tax, and including the expenses of the New York Office entirely borne by this Company (*vide* paragraph 6 of the report to June 30 last), but exclusive of cost of repairs of cable, amounted to £17,555 12s. 7d., leaving a balance of £25,791 1s. as the net profit, making, with £968 0s. 3d. brought forward from the previous half-year, a total of £26,759 1s. 3d. For the corresponding period of 1889, the working expenses and other payments amounted to £15,509 5s. 8d.

Interim dividends of 3s. 6d. per share for the quarter ended September 30, 1890 (paid October 24, 1890), and of 3s. 6d. per share for the quarter ended December 31, 1890 (payable January 24, 1891), together amounting to £21,248 10s., have been declared, and the balance of £5,510 11s. 3d. on the revenue account has been carried forward.

An interruption of the main cable, occasioned by a vessel's anchor, occurred on September 1st last, near the Green Bank, and was repaired on September 8th. The repairing operations have cost £1,629 12s. 5d., which has been charged to the reserve fund account as heretofore.

In the case of the Anglo-American Telegraph Company *v.* Cie Française du Télégraphe de Paris à New York, the appeal to the Council of State, mentioned in the report to June 30, 1889, is still pending.

[*A full report will appear in our next issue.*]

## CITY NOTES, &c.

**BRAZILIAN SUBMARINE TELEGRAPH COMPANY.**—The receipts of this Company for the week ended January 9th amounted to £5,487.

**CITY AND SOUTH LONDON RAILWAY.**—The receipts of this Company for the week ended January 10th amounted to £748.

**EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED)**.—Our advertisement columns contain notices that the whole of the Company's £320,000 Six per Cent. Debentures falling due February 1st next, together with the last half-yearly coupon on these Debentures for the accrued interest to February 1st, will be paid by the Consolidated Bank (Limited), 52, Threadneedle-street, E.C., on and after February 2nd. The Debentures will be paid off at par, and both the Debentures and coupons must be left three clear days previously for examination at the bank, where forms for specifying the same may be had on application.

**ELECTRIC CONSTRUCTION CORPORATION (LIMITED).**—The International Trustee, Assets, and Debenture Corporation (Limited) is authorised by the Corporation to receive applications at par for £100,000 Six per Cent. First Mortgage Debentures. The prospectus (which will be found on page xiv.) states that this issue is made in consequence of the growth of the business of the Corporation, and for the purpose of extending its operations and repaying a bankers' advance of £30,000 (secured by temporary debentures) which has enabled the Corporation to complete and equip its new works at Bushbury, Wolverhampton. The profit and loss account from June, 1889, to September, 1890, shows a profit balance of £52,639. The annual sum required to pay the interest on this debenture issue is £6,000. The security for the debentures will be the freehold and leasehold properties, plant, machinery, stock, book debts, patent rights, shares in other companies, goodwill, and other assets of the Corporation, the whole of which stood in the balance-sheet of the Corporation at September 30, 1890, at £586,648. 16s. 11d. The freehold and leasehold properties, plant, machinery, stock, &c., have been valued at £146,833 by Messrs. Farebrother, Ellis, Clark, and Co., who, speaking from some experience of electrical works and machinery, add that "the buildings at Bushbury are perhaps the finest and best constructed as electrical factories in the United Kingdom, and the plant and machinery are all of the newest and best possible workmanship, and capable of dealing with the growing demand for electrical appliances for various objects to a vast extent." The book debts of the Corporation on September 30, 1890, stood at £104,882. 5s. 5d. Prospectuses may be obtained from the bankers of the Corporation, at the offices, and from the International Trustee, Assets, and Debenture Corporation (Limited), 13, George-street, Mansion House, London, E.C. The subscription list closes on Wednesday next, the 21st inst.

**GLOBE TELEGRAPH AND TRUST COMPANY.**—The Directors of this Company have declared an interim dividend of 1s. 9d. per share.

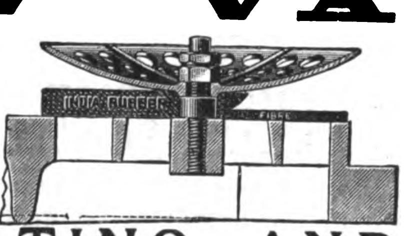
**ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).**—Mr. Egerton H. Clarke has joined the Board of this Company.

**VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY (LIMITED).**—Warrants for an interim dividend at the rate of 3 per cent. per annum have been posted to the shareholders. The Stock Exchange Committee have appointed Friday, January 16th, a special settling day in this Company's shares Nos. 1 to 13,144, and debentures Nos. 1 to 572.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY.**—The traffic receipts of this Company for the week ending January 9, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,434.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 662.—Vol. XXVI. FRIDAY, JANUARY 23, 1891. Price Fourpence.

## NOTES.

Although the process of hastening tanning by electricity is as yet in its infancy, the case of Worms and Balé v. Groth, which was decided last week, presented two points of interest. It was of the nature of a test case of the provisions of the Patent and Designs Act of 1883, with regard to the International Convention. Owing to want of space we have not given the arguments by the counsel in full, since the matter is thoroughly dealt with in the judgment. The invention was originally patented in France, and was afterwards patented in America, the drawings being identical, and the specification practically the same An abstract of this latter patent, in the United States Patent Office Journal, was received in England before the date of the English patent. It was pleaded that under the International Convention this would not be a "prior publication," but it was decided that the English patent was thereby invalidated. Attempts have been made to show that such official publications should not be treated as actual publications, but since they are reproduced in many technical journals they are undoubtedly a most efficient form of publication. The second point is one of more general interest, and concerns one of the most common kinds of infringement of a patent. To all of our readers who are inventors, and, indeed, to those who own or are interested in patents, we commend the careful perusal of Mr. Moulton's speech.

Of electrical tanning it is at present too early to say much. The terminology of the art has been enriched by two expressions put forward with some modesty by Mr. Justice Romer—"statical tanning," and "dynamical tanning." We shall soon hear of "electro-kinetic dermatization." It is true that a scientific explanation of the process was not called for during the recent action, but we doubt whether a clear theory could have been put forward among the three professors, headed by the President of the Institution of Electrical Engineers, to say nothing of the other experts. In the present state of knowledge it is sufficient to speak of the electrical action as being a hastening of the combination of tannin with the gelatin. Whether it be due to the acceleration of osmosis or to electrolysis, whether the current acts on the liquor or on the hides, or on neither, but merely facilitates the diffusion of the former through the latter, must be left to future experiments. That leather can be produced by this process with a most important saving of time is undeniable, and that the result may be either good leather or bad leather is worthy of a passing remark.

Mr. Swinburne has recently discussed in *Industries* the theories which have been advanced to explain the curious rise of pressure which occurs on the Ferranti mains. His contention that the effect is due to armature reactions in the dynamo was first explained in his Paper on condensers read before the Physical Society on December 12th, and has given rise to an interesting controversy. Our readers are already familiar, from articles we have published recently by Messrs. Glazebrook, Kapp, and Fleming, with what may be called the orthodox theory of the phenomenon, that of electric resonance, first clearly explained by Dr. Hopkinson in 1884. Mr. Swinburne's objection to this theory appears merely to refer to its name, his argument being that, as true resonance can only occur at one particular frequency, it is inaccurate to use the term to describe an effect which takes place more or less at all frequencies. This may be true, but is of minor importance. The point is, will Dr. Hopkinson's equation for the rise of volts, which Mr. Swinburne accepts and quotes, give an approximately correct result when the actual values are substituted for the self-induction of the armature, the frequency of the current, and the resistance and capacity of the cable. The advocates of the resonance theory do not assume that the condition for perfect resonance is fulfilled. When this is so, it is true, as Mr. Swinburne says, that a slight variation in the frequency of the current will produce a great fall in the voltage; but under ordinary circumstances this sensitiveness will not be exhibited, so that the absence of any such effect in the Deptford case is no argument against the theory.

The critical value of the inductance to give the greatest effect is far too large to occur in the transformers or in the armature of the dynamo, and the enormous potential of over ten million volts which this induction would cause has evidently nothing to do with the case, and is only instructive in showing the need, in alternate current work, of guarding against combinations in which the true resonance condition is approximately satisfied. Mr. Swinburne, however, shows that it is only necessary to have a self-induction of ·4 henrys somewhere in circuit to produce the rise of volts actually observed, and this does not appear to be too great for a large transformer whose secondary is working at very much below its full load. We cannot

Digitized by Google

agree with Mr. Swinburne that the self-induction of a converter, whose ratio is unit T, is the same as if the primary and secondary coils were joined in series in opposite directions. The two currents, although of equal amount, and in very nearly opposite phase, are sufficiently different to have an important magnetising effect, irrespective of any magnetic leakage which may take place in the converter, and although no measurements have been published, we believe that the difference in phase between the amperes and volts given out by the Deptford transformers is quite sufficient to account for the rise in volts observed on the mains.

It must not be supposed that we object to Mr. Swinburne's armature reaction theory. On the contrary, we think it exhibits his well known originality of thought and boldness of style, and is worthy of most careful consideration. It is quite independent of the theory of resonance, and may still be the explanation of part of the Ferranti effect. The Westinghouse constant current alternator, described in *The Electrician* for April 5th and June 13th of last year, is an instance of the possibility of altering the strength of field by merely shifting the phase of the armature current. In that dynamo the re-action of the armature on the field is so great that the voltage rises with the resistance of the external circuit so as to keep the current the same. It is this effect in a smaller degree which Mr. Swinburne assumes to take place in the Ferranti dynamo, the necessary shifting of phase being brought about by the condenser current whose phase is necessarily different from that of the other currents. The reaction of the armature current on the field as its phase is varied is an important subject which has yet to be studied in connection with the design of alternators. We agree with Mr. Swinburne that the idea of self-induction in connection with the armatures of alternators is misleading, and we would add that it is equally so in connection with the coils of transformers. A more simple and practical view is to consider merely the lines of force enclosed, and the reactive influence of the currents on them.

M. Branly has recently found that the spark of a Holtz machine or induction coil has a remarkable effect in temporarily decreasing the resistance of certain badly-conducting mixtures, such as powdered or oxidised metals, or pastes formed by immersing filings of iron, copper, or other metals in a non-conducting fluid. The effect is generally increased by connecting one or both of the sparking terminals with the substance under test, although the spark alone may be sufficient. In one case the resistance of a junction of two pieces of oxidised copper, as measured by a Wheatstone's Bridge, was reduced from 80,000 ohms to 7 ohms in this way. The diminution of resistance of such conductors may last for as long as 24 hours, unless the substance is disturbed by vibrations, in which case the high resistance is restored. The effect would appear to be the result of the high potential momentarily applied to the substance when the sparking takes place, and is probably only an exaggerated instance of the general tendency of high voltages to lower the resistance of bad conductors or dielectrics. The power of such voltages to prepare adjacent surfaces for conduction is often shown in overcoming the obstruction presented by a dirty joint between two copper wires. Such a connection, although appearing of infinite resistance when measured by a Wheatstone's Bridge, gives no trouble when high voltages are used, and if its resistance is measured by the Bridge after the current has passed its resistance is found to be inappreciable.

The impulsion effects of the photo-electric cells, described in Professor Minchin's paper on Photo-electricity, of which an abstract is given in another column, are very remarkable, and the explanation of them when found may very probably throw light on some of the obscure problems of molecular physics. The suggested application of the seleno-aluminium cell to the construction of a photometer capable of accurately comparing the light from different coloured sources, appears to be as hopeful as any of the chemical methods which have been suggested, and such an instrument is greatly needed. We direct our readers' attention to the announcement that the Paper will be discussed at the annual general meeting of the Physical Society on February 13th, and that the author, in compliance with a suggestion made by the President, will then repeat some of the experiments.

The revival of public interest has given rise to much inflated talk in the non-technical Press on the subject of electricity, but it remained for our weekly contemporary, the *World*, to outshine all previous performances in this direction. A few weeks ago that journal treated its readers to an amusing lucubration on the lighting of London, and in its last issue it outdoes itself in an article called "Lightning in Harness." A somewhat infelicitous title, since it is not, as we at first suspected, an advertisement of a certain eminent gentleman, disguised after the manner which now obtains with the *St. James'* and *Pall Mall Gazettes.* As a sample of the whole we quote the first paragraph:—"The electrician is your modern miracle-worker. In the sixteenth century he would have been convicted of collusion with the Devil, and the town would have turned out to see him fried. He has bottled Jove's lightning, and he retails it by the ampere. He sits by his dynamo like Zeus on Olympus, and he shakes the earth with his volts of pressure. At the wag of his forefinger, a hundred full moons dispel darkness from the habitations of men. His voice traverses the ocean depths and the haunts of leviathan, whom he could hook an he would! He can hold in the hollow of his hand the lightning equivalent of the force of five thousand horses—unconscious of its presence, and proof against sudden death. He is a walking paradox: he is two characters in one, for he is a lord because he is a thrall; he soars into the empyrean because he plods on the earth, plantigrade; he is Baconian philosophy incarnated, for more than any of the sons of men does he master Nature by obeying her. We stand uncovered before this astonishing thaumaturgist; for if he goes on at his present rate he will so transform industry and social conditions that the world will hardly know itself in fifty years." This may be English, though we doubt it. It is certainly nonsense.

Digitized by Google

**Lowestoft.**—The Town Council has decided to apply for an electric lighting order.

**Dublin.**—The discussion on the electric lighting tenders, to which we referred in our last issue, still continues.

**Stockholm.**—The electric lighting of Stockholm has, we learn, been entrusted to Messrs. Siemens and Halske, of Berlin. The installation will comprise 15,000 glow lamps.

**Woking.**—The Electric Light Committee of the Dorking Local Board paid a visit to Woking last week to inspect the electric light.

**Berlin.**—All theatres and places of amusement in Berlin capable of accommodating more than 800 persons have been ordered to be lighted by electricity by January next.

**Derby.**—At the last meeting of the Town Council, the report of the Electric Lighting Committee, recommending the obtaining of a report from Sir Frederick Bramwell, was adopted after some discussion.

**Cable Extensions.**—The s.s. "Silvertown" completed, on the 15th inst., the Chorillos-Yquique section of the new Central and South American Company's cables between Chorillos, Yquique, and Valparaiso.

**The East African Company's Land Lines.**—The Imperial East African Company have opened a telegraph station at Malindi, on the land line they are constructing towards the Lakes. The line is now open to the public for traffic.

**Cambridge.**—Prof. Ewing delivered his inaugural lecture on Tuesday. A grace will be brought forward at the next congregation to confer the degree of Master of Arts (Honoris Causa) upon the new professor.

**Tunis.**—A telephone exchange will be opened at Tunis about the middle of February, and already about 100 subscribers have been obtained. The suburbs of La Goulette and of La Mersa will be included in the system.

**Royal Society.**—At the last meeting of the Royal Society the following papers were down for reading:—H. Wilde, F.R.S., "On the Unsymmetrical Distribution of Terrestrial Magnetism." T. Andrews, F.R.S., "The Passive State of Iron and Steel.—Part II."

**Utilisation of the Water-power of the Reuss.**—A Zürich Company is endeavouring to obtain a concession from the authorities of Aargau for building a canal on the left bank of the Reuss. The power obtained is to be used for industrial purposes.

**The Consumption of Electricity in Paris.**—The gross receipts of the central stations of the Compagnie Continentale Edison for December last amounted to £7,879. Taking the price per 1,000 watt-hours at 1fr. this denotes an output for the month of about 197,000 units.

**Electric Lighting and Transmission of Power at Spandau.**—The Berliner Maschinenban Actien-Gesellchaft has just completed an installation consisting of 3,000 glow lamps and 80 arcs at the Spandau Small Arms Factory. A 29 horse-power electric motor is also used to drive boring machines, lathes, &c.

**The Mayer Electric Motor.**—The American technical journals describe a motor designed by a Mr. Mayer, of New York. The motor is of the single-magnet, two-pole, iron-clad type. The whole of the magnetic circuit is stamped out of one sheet of Swedish iron, the sheets being bolted together to form the magnet frame.

**A New Insulator.**—Mr. F. N. Gisborne, the superintendent of Canadian Telegraphs, has recently tested the insulating properties of samples of the petroleum-saturated sand, which is found in large quantities in the Athabasca district in North-West Canada, and speaks of it most highly. This sand lies exposed all along the Athabasca River, and has a saturation of 12 per cent. of petroleum.

**Eastbourne.**—The Eastbourne Electric Lighting Company contemplate considerable additions to their plant. An order has been given by the Marquis of Hartington for an installation at Compton-place, and the electric light is also to be introduced into the Clifton Hotel. There are now between 3,000 and 4,000 lamps connected to the alternate current mains, exclusive of those which are run off the arc light mains.

**Glasgow.**—There does not seem to be much disposition on the part of the special committee on electric lighting to promptly carry out the Provisional Order of last Session. Mr. Crompton's report has been in type several months, and within the past few weeks Prof. Jamieson has been called in to advise the committee. Meanwhile the Board of Trade has inquired as to what system of lighting has been resolved upon.

**Village Lighting in Germany.**—The Allgemeine Elektricitats Gesellschaft of Berlin have concluded arrangements for lighting the villages around Nuremberg. A central station is to be established in a factory at Schnigling, and sub-stations will be erected as required. The price for current has been fixed at what is equivalent to 9½d. per Board of Trade unit, with a rebate up to 5 per cent. according to the consumption.

**Private Telephone Lines.**—In the country the telephone is beginning to make its way in the direction of private lines and local exchanges. The Directors of the Hebden Bridge Co-operative Industrial Society have just decided to adopt a system of telephonic communications between the Central Stores and their several country branches, and the work has been entrusted to Mr. R. S. Blackburn, of that town.

**London Electric Supply Corporation.**—This Company was sued on Monday by Mr. Samuel for £72 for damage done to his stable and its contents. The stable is in Brad-street, close to the bridge of the South-Eastern Railway Company at Waterloo Bridge. According to the plaintiff the servants of the Company trespassed on to his roof at the stable while cutting the electric cable which runs to Deptford to test it. A verdict was given for the plaintiff for £65.

**The Hanover-square School of Electrical Engineering.**—We are informed that Mr. Léon Drugman, the manager of this school, has obtained the consent of Sir Samuel Canning, Dr. P. Herbert Carpenter, F.R.S., Mr. Gisbert Kapp, and Prof. Alex. B. W. Kennedy, F.R.S., to form a permanent "Consulting Committee," who will have the control of the teaching of the school. We congratulate the school upon having secured such valuable co-operation.

**Electric Light along a Railway.**—Not content with adopting electric head-lights for their locomotives, the Americans now propose to actually light a railway line. The line of the Pennsylvania Company from Frankford Creek to Povuessing Creek, at Torresdale, a distance of nearly seven miles, is to be lighted by electric lights placed at intervals along the side of the track. The line to be lighted runs through a populous district, and has long been noted for the frequency of accidents on it.

**The Woodward Storage Battery.**—Dr. Woodward, of the Woodward Electrical Company of Detroit, has arrived in this country with a view of establishing electric works in England for the manufacture of the Woodward Battery. One special advantage claimed by Dr. Woodward for his new type cylindrical battery, which is made in various sizes, from 100 ampere-hours capacity up to 2,000 ampere-hours, is that it will stand a much higher rate of charge and discharge than the grid form of plate, and buckling of the cylinders is impossible.

**The French Telegraph Service.**—According to *La Lumière Electrique*, the telegraphic work in connection with some recent trials at Draguignan, near Toulon, proved too much for the French telegraphic service, the leading Paris papers complaining that their despatches took seven hours to traverse the 500 miles separating Draguignan from the capital. As Draguignan is only a town of some 10,000 inhabitants, it is perhaps surprising that the messages arrived as soon as they did, if no additional apparatus and staff were available.

**Load Diagrams of the St. James's and Pall Mall Company.**—The following footnotes should have been printed under the load curves of this Company's station, which appeared on page 334 of our last issue.

**Contracts by Telephone.**—On Thursday, last week, in the Westminster County Court, the case of Mitchell *v.* Isaacs came before Judge Bayley. The plaintiff sought to recover 13s. 6d. for a stall ticket for Drury Lane Theatre. The case for the plaintiff was, that in December they got a message through the telephone to send a stall ticket to 2, Tavistock-square, for Mr. A. Isaacs. The ticket was sent and handed to a servant. Defendant denied ordering the ticket, and said it must have been a joke of someone's. He had never had the ticket. Judgment was given for the defendant.

**City and South London Railway.**—The traffic receipts of this Company for the week ended January 17th amounted to £758, against £748 for the week preceding. The line has now been open to the public for a month, the regular service of trains having commenced on December 18th. The total receipts for this period amount to £3,453, showing that over 414,000 passengers have passed the turnstiles, the daily average, if we exclude Sundays (when the trains do not run) amounts, therefore, to 15,347. If the monthly receipts are maintained throughout the year at this figure they will amount to £41,436.

**Relative Consumptions of Gas and Electricity in the Metropolis.**—Taking the figures quoted in Mr. Bailey's recent Paper before the Society of Arts, Mr. John T. Sheard, in a letter to the *Journal of Gas Lighting*, works out that if all the incandescent lamps at present in use in the Metropolis were replaced by gas-burners giving the same amount of light an additional annual consumption of nearly 500,000,000 cubic feet might be anticipated. He hastens, however, to point out that this is only $1\frac{2}{3}$ per cent. of the present total gas consumption of the Metropolis, which attained in 1890 the gigantic total of 30,707,000,000 cubic feet.

**The St. Luke's Vestry and Electric Traction.**—On Monday last the St. Luke's Vestry, accompanied by their surveyor and the engineer of the North Metropolitan Tramways Company, visited the General Electric Power and Traction Company's electric cars and installation on the Barking-road section of the North Metropolitan Tramways Company's system. Having made a minute inspection of the working of the cars, the members of the Vestry expressed themselves as greatly pleased at all they had seen. As the Tramway Company has signified its intention to run electric cars from Stamford-hill to Moorgate-street, and as this Vestry controls a portion of the route, their inspection was on that account most exhaustive.

**Brighton.**—At the last meeting of the Town Council, the General Purposes Committee submitted draft objections to the application of the Brighton and Hove Electric Light Company for a Provisional Order. The adoption of the Report met with some opposition, one member asking why, if the Corporation were not going to supply a certain part of the town, they should prevent a company from doing so? Alderman Ewart denied that the Corporation policy was a dog-in-the-manger policy. He denied that they were spending the ratepayers' money. They were making an investment which would turn out, if they only supported it as they should do, one of the grandest investments ever made in any town of the kingdom. The report and the draft objections were finally adopted.

**London Chamber of Commerce.**—The following are the agenda for the meeting of the Electrical and Allied Trades' Section Committee to be held on Monday next. (1) Board of Trade Provisional Orders in regard to telephones, suggested modifications in; (2) Board of Trade rules and regulations, re overhead wires; report of Sub-Committee; (3) Board of Trade forms of accounts, report of Sub-Committee; (4) Board of Trade Electrical Standards Committee, correspondence in connection with; (5) Proposed exhibition in London of electrical appliances, letter from Mr. Seymour Wade; (6) St. Pancras Electrical Exhibition, letter from Messrs. W. T. Goolden and Co.; (7) Automatic Electric Railway signalling, letter from Mr. Martin Perls proposing address on "Is railway travelling safe as managed at present?" (8) Other matters.

**St. Pancras.**—Mr. Alderman T. E. Gibb, clerk of the Vestry, presented a report to the Electricity Committee last week on the subject of the holding of an exhibition of electrical appliances at the Vestry Hall, with a view of informing those who are to be served by the Stanhope-street Station and the parishioners generally on questions concerning the uses of electricity for lighting purposes and motive power. By June next, he stated, the Stanhope-street Station will be completed, and already many of the inhabitants of the district were asking for information about terms, mode of supply, and the most economical mode of fitting up their houses and shops. This information the proposed exhibition would supply. The Committee have approved the proposal conditionally upon no part of the cost being charged to the rates.

**Photographic Registration of the Movements of the Seismo-Microphone.**—According to the *Rivista Scientifico-Industriale*, Signor Baratta, finding some defects in the method of mechanical registration of the motions of the seismo-microphone, has substituted a photographic system with advantage. The device is briefly this:—The telephone wire is connected with a subterranean microphone. Before the telephone-diaphragm, and connected with its centre by a fine aluminium wire, is a short slip of the same metal, fixed below, and having a curved piece at the top, which rests against a small mirror, movable about a horizontal axis. This mirror reflects the light from a lamp and lens to photographic paper on a rotated drum. The light is momentarily shut off every quarter of an hour, by a shutter arrangement, worked electro-magnetically by the clockwork which moves the drum.

**Matlock.**—At the meeting of the Local Board last week some reports were presented upon the question of electric lighting. Mr. Etheridge said he had no desire to bore the Board with a lot of correspondence, but his object was to ask for a committee to be appointed, empowered with authority to go into the subject of electric lighting. He had a letter from the Chairman of the Lynton Local Board, showing that they were highly pleased with the electric light there. Mr. George Fletcher, electrician to the Midland Railway Company, wrote that Mr. Cameron, whose opinion could be relied upon, was convinced, after visiting the district, that there would be no difficulty in getting at least 100 horse-power from the river without interfering with the works already using water-power. Mr. Etheridge, in conclusion, suggested that they should accept the offer of Mr. Geen, of Okehampton, to come and report, and that a committee should be formed to meet the engineers. The resolution was carried *nem. con.*

**Henderson Multiple Carbon Arc Lamp.**—The cost of trimming arc lamps was very early recognised to involve a not inconsiderable part of the total operating expense in arc lighting, and to this fact, says the *Electrical Engineer* of New York, the creation of the double carbon lamp is due. Still another method which has lately been brought out consists in providing a number of sets of carbons, each of which is successively brought into action as its predecessor is consumed. A lamp based upon this principle has recently been devised by Mr. W. B. Henderson, of Crafton, Pa. Six pairs of carbons are employed, mounted on two hubs which are controlled by the lamp mechanism. Each pair of carbons starts into operation at an angular position, and as they burn away the hubs are revolved so as to bring the points towards each other; so that when fully consumed the carbons are exactly in a horizontal position. When this point is reached, the mechanism automatically brings the succeeding pair of carbons into circuit, and this operation is continued until all the carbons are consumed.

**The Perrier-Lloyd Generator.**—Two actions in connection with this primary battery were heard last week at the Sheriffs' Court. Mr. Joseph Mitchell, of Bolton Hall, Yorkshire, a colliery proprietor, was the plaintiff; and the defendant, Mr. De Vesey, was the proprietor of the patent known as the "Perrier-Lloyd" for generating electricity by chemicals. Plaintiff stated that in July, 1889, the defendant called upon him and showed him two pamphlets, which went to prove that this patent could produce electricity free of cost, and was to be applied to the lighting of the streets of London under the direction of Sir Henry Roscoe. He persuaded him to advance him £2,800 to float the scheme. Mr. Scudder, principal assistant to Sir Henry Roscoe, gave evidence to the effect that the system was tried in London, and found to be an utter absurdity. The jury awarded the plaintiff the sum of £2,800 damages. In the second action, Mr. William Cox, of Fairfield Hall, Harrogate,

Digitized by Google

Yorkshire, sued for the return of £2,200 advanced to the defendant under similar circumstances. The jury assessed the damages at that amount.

**Sophia.**—In our issue of December 5, 1890, we referred to the discontent which had been aroused by the perfunctory manner in which the Committee entrusted with the examination of the electric lightings tenders, invited by the municipal authorities of Sophia, had performed its duties. The following are some further particulars connected with this scheme. The plant was to be installed at the Government printing-office, and current was to be supplied to the Palace about half-a-mile away, and to the Sobranje, 286 yards distant. The total light required was estimated at 12,500 candles by arcs, and 25,000 candles by incandescents. A storage battery was to be employed as a reserve. The following tenders were received:—Egger and Co. (Vienna), £9,328; Ganz and Co., £9,535; Schuckert (Nuremberg), £9,768; Siemens and Halske, £11,158; Sautter-Harlé, £11,600; Société Gramme, £13,440; Kremenezky, £13,500; Compagnie Continentale Edison, £15,120 and £15,881; Crompton and Co., £11,120 and £15,290; Allgemeine Elektricitäts Gesellschaft, £15,940; Southgate Engineering Company, £16,896; Société d'Appareillage Électrique (Paris), £48,000. The contract was given, as we announced previously, to Egger and Co., of Vienna.

**Lightning in a Cable Station.**—The following extract from a letter of Mr. Bonnard, by the West African Telegraph Company, may be of interest:—

"Kotonou, November 30, 1890.

"I have also the honour of confirming my service telegram of the 27th instant, in which I informed you that the lightning struck our house, happily without causing any harm beyond damaging some furniture. The weather was fine, the sun was shining, and only a dry storm-cloud was threatening on the Porto Novo side. All at once a tremendous explosion resounded, and a light, taking the form of a ball of fire, ran along the air passage of the ventilator to the verandah. At that moment we were receiving a despatch from Accra. Nobody was injured, but Mr. Orsini was hurled about two yards from the door without, however, sustaining any serious bruises; and Mr. Thomas and myself received a violent shock. Several wires of the lightning guard were fused. This is the first time such an accident has happened to us, and I think I can explain it in this way:—During the late hostilities, the wood which used to lie about 200 yards on the west of our station was cut down. The trees in it were very high, and, as these trees and thick damp bushes no longer exist around us, the result is that our metal roof, which has an area of about 150 square yards, attracts the atmospheric discharges more readily. I think that to fix a lightning protector would be a useful precaution for the future. The damage done to our furniture is as follows:—The large beams of the ventilator were split from one end to the other, the partitions of the office were much shaken, the roof has been badly damaged, and two legs of the bedstead in Mr. Lefebore's room twisted. The station clock has either kept very bad time or not gone at all since this accident.

**The German Telegraph Tariff.**—On the advice of Herr von Stephan, the German Government has reduced the tariff for inland telegrams from six to five pfennigs a word, with a minimum charge of fifty pfennigs, or sixpence. Herr von Stephan has, however, resisted all demands for a tariff for press telegrams similar to that existing in England. Speaking last week before the Budget Committee of the Reichstag, Herr von Stephan, in the name of the Federal Government, declared that he saw no good and sufficient reason to yield to the demand of the 234 newspapers which had petitioned for a reduced tariff for press telegrams. These newspapers, he said, had already enjoyed advantages enough in the lowness of the rates for their postal transmission, as well as in the comparative cheapness of the wires of which they might have the special use at night. Of over 14 million telegrams that were last year sent and delivered within the Empire only 1·29 per cent. were press messages, representing a revenue to the State of about 153,000 marks, or £7,600. If the press were granted a special price for telegrams, charitable societies, universities, &c., would be sure to follow suit with similar requests for exceptional treatment which could never be accorded. The present tariff was not too high, as witness the many unnecessary telegrams which the newspapers printed.

**The Central London Railway.**—The following are the principal differences between the Central London Railway Bill of last year and that which will come before Parliament during the present Session. The line as now proposed runs from Shepherd's Bush to Cornhill, and the western terminus will be on land adjoining the Shepherd's Bush sidings of the London and North-Western Railway. This makes the entire length of the line six miles, instead of four and a-half miles, and, besides accommodating a wider district, enables the Company to purchase the land for its western terminus at a much lower figure than would be required to acquire expensive house property like that at Kensington. The Post Office station has been moved to the north side of Newgate-street, presumably in deference to the views of the authorities of St. Paul's Cathedral. A station is to be made at Chancery-lane. A new station is to be constructed between the Marble Arch and Oxford-circus, at the corner of Davies-street, near Bond-street. A new station is also proposed at Notting-hill Gate, in close proximity to the existing underground railway, which will enable passengers to change there from one line to the other; and the extension to Shepherd's Bush also involves a new station at Lansdowne-road (opposite Holland Park) and the terminal station at Shepherd's Bush. An examination of the plan shows that the line generally is placed at a somewhat deeper level than last year.

**The Edinburgh Municipal Electric Lighting Order.**—The Leith Corporation have lodged objections against the Edinburgh Electric Lighting Provisional Order. They point out that the rates of Leith are impledged similarly with those of Edinburgh in connection with the joint gas undertaking, and they protest in the strongest possible manner against the Corporation of Edinburgh having the power to transfer their electric lighting undertaking to the Gas Commissioners, and so cast the financial and other responsibilities of the undertaking upon funds in which Leith and Edinburgh are equally interested. The Leith Corporation desire the insertion of a proviso to the effect that such transfer shall not be made unless agreed to by them, and that if they consider that the price of gas supplied is higher than it would have been put but for the introduction and supply of electric light by the Corporation of Edinburgh, they may from time to time make a representation to the Board of Trade that such is the case, and the Board of Trade may direct an inquiry by a referee into the truth of the representation, and if the referee find that the price of gas is higher by reason of the exercise of the powers of the Order, he shall fix the extent to which it is so affected, and shall order a corresponding reduction of the price of gas within the burgh of Leith, the gross amount of such reduction to be recoverable from the Corporation of Edinburgh by the Gas Commissioners

**The Westinghouse Interests.**—Referring to the recent financial difficulties of the Westinghouse Company (see *Electrician*, January 16th, page 339), *Modern Light and Heat* says:—"The crisis has come at last, and George Westinghouse, jun., is seriously embarrassed financially. The story has been told by the daily press throughout the country, hence it is not necessary that we should repeat it. Let it suffice that Pittsburg capitalists have had to come to the relief of Mr. Westinghouse, and still, with all their efforts, only $520,000 is reported as subscribed, which amount has been contributed, it is stated, by forty-five individuals and corporations, Mr. Westinghouse giving as security for the amount a mortgage on his property at Homewood, consisting of twenty-three acres of land and a mansion; also thirty-five acres of land at Swissvalle and the Watts farm of twenty-three acres; also an assignment of such personal collateral as the Committee shall be able to obtain from Mr. Westinghouse. These facts, it would seem to us, argue that the affairs of Mr. Westinghouse are even worse than has been published. . . . If, as reported by the Examining Committee, the gross earnings of his various enterprises for this year amount to $16,550,000, it would appear to us that it ought to have been an easy matter for Mr. Westinghouse to raise from any one or two financial corporations of Pittsburg, or anywhere else, notwithstanding the tight Money Market, the amount that has been subscribed. . . . The Westinghouse Electric Company's debt is stated as being $3,339,900, to offset which it is credited with accounts receivable, cash, &c., amounting to $1,436,000, and material in stock amounting to $780,000. Quite a different showing from that on made in its statement the first of last June."

## INSTITUTION OF ELECTRICAL ENGINEERS.

PRESIDENTIAL ADDRESS OF PROF. WILLIAM CROOKES, F.R.S.

### Electricity in Transitu : from Plenum to Vacuum.

(*Continued from p. 327.*)

*Radiant Matter.*

By means of this tube (Fig. 9), I am able to show that a stream of ultra-gaseous particles, or radiant matter, does not carry a current of electricity, but consists of a succession of negatively electrified molecules whose electrostatic repulsion overbalances their electro-magnetic attraction, probably because their speed along the tube is less than the velocity of light. The tube has two negative terminals A, A′, close together at one end, enabling me to send along the tube two parallel streams of radiant matter, rendered visible by impinging them through holes in a mica diaphragm on a screen of phosphorescent substance. It is exhausted to a pressure of 0·1 mm. I connect one of the negative poles, A, with the induction coil, and the luminous stream darts along the tube from C to D parallel with the axis. I now connect the other negative pole, giving a second parallel stream of radiant matter. If these streams are in the nature of wires carrying a current they will attract each other, but if they

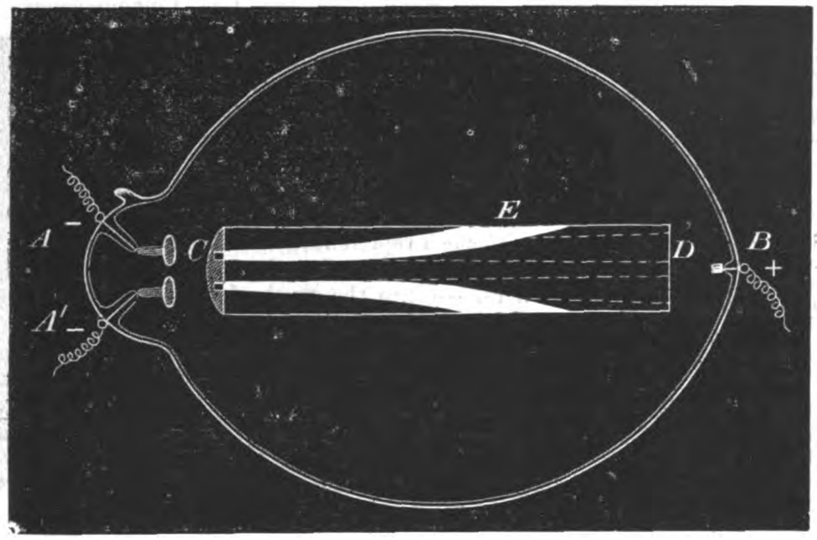

Fig. 9.—Pressure = ·1 mm. = 131·5 M.

are simply two streams of electrified molecules they will repel each other. As soon as the second stream is started you see the first steam jump away in the direction C E, showing strong repulsion, proving that they do not act like current carriers, but merely like similarly electrified bodies. It is, however, probable that were the velocity of the streams of molecules greater than that of light, they would behave differently, and attract each other, like conductors carrying a current. To ascertain the electrical state of the residual molecules in a highly exhausted tube, such as you have just seen, I introduced an idle pole or exploring electrode between the positive and negative electrodes in such a manner that the molecular stream might play upon it. The intention was to ascertain whether the molecules on collision with an obstacle gave off any of their electrical charge. In this experiment (Fig. 10, P = 0·0001 mm., or 0·13 M.*) it was found that an idle pole, C, placed in the direct line between the positive and the negative poles, A B, receiving in consequence the full impact of the molecules shot from the negative pole, manifested a strong *positive* charge. In a variety of other experiments made to decide this question, the electricity obtained was always found positive on testing with the gold leaf or Lippman's electrometer, and when the idle pole was connected to earth through a galvanometer a current passed as if this pole were the copper element of a copper-zinc cell, indicating leakage of a current to earth, the idle pole being positive. If, instead of sending this current to earth, the wire was connected to the negative pole of the tube, a much more powerful current passed in the same direction.

* M = one-millionth of an atmosphere.
1,000,000 M = 760 mm.
" = one atmosphere.

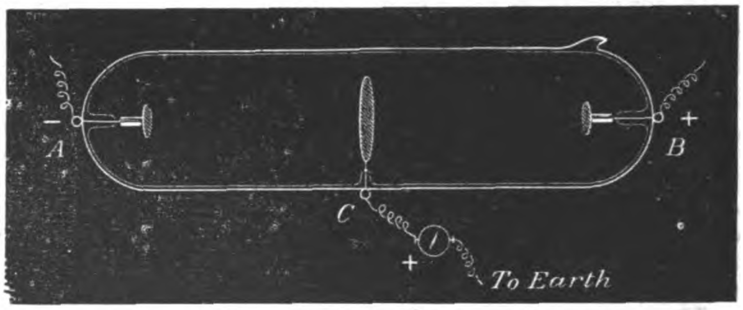

Fig. 10.—Pressure = ·0001 mm. = ·13 M.

*The Edison Effect.*

An exactly parallel experiment has been made by Mr. Edison, Mr. Preece, F.R.S., and Prof. Fleming, using, instead of a vacuum tube, an incandescent lamp. They found that from an idle pole placed between the ends of the filament the electricity always flowed as if the pole were the zinc element of a copper-zinc cell; having repeated their experiments I entirely corroborate them. I get a powerful current in one direction from an idle pole placed between the limbs of an incandescent carbon filament, and one in the opposite direction from an idle pole in a highly exhausted vacuum tube. This discrepancy was extremely puzzling, and I tested, with a similar result, very many experimental tubes made in different ways. The electricity obtained from an idle pole placed between the positive and negative terminals in a highly exhausted tube was always strongly *positive*, and it is only recently that continued experiment has cleared the matter up.

Some of the contradictory results are due to the exhaustion not being identical in all cases. In my vacuum tubes the directions of current between the idle pole and the earth changes from negative to positive as the exhaustion rises higher. Testing the current when exhaustion is proceeding, there is a point reached when the galvanometer deflection—hitherto negative—becomes *nil*, showing that the potential at this point is zero. At this stage the passage of a few more drops of mercury down the pump tube renders the current positive. This change occurs at a pressure of about 2 mm.

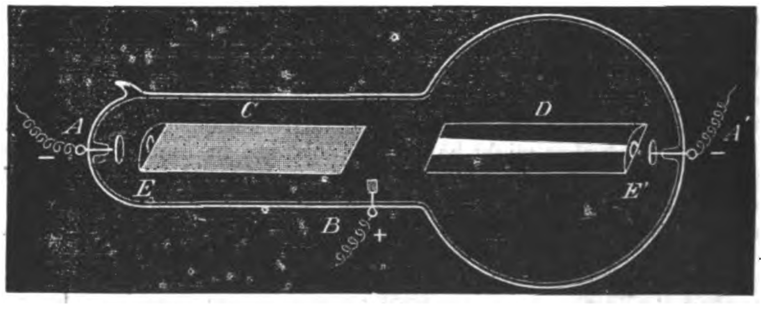

Fig. 11.—Pressure = ·0011 mm. = 1·3 M.

After this point is reached, when the induction current is passed through the tube, the walls rapidly become positively electrified, probably by the friction of the molecular stream against the glass, and this electrification extends over the surface of any object placed inside the tube. I will show you how this electrification of the inner walls of the tube acts on the molecular stream at high vacua. In this tube, Fig. 11

(P = 0·001 mm. or 1·3 M), are fixed two exactly similar phosphorescent screens, C and D; at one end of each is a mica gate, E, E', with a negative pole A, A', facing it. One of the screens, C, is in the cylindrical part of the tube and close to the walls; the other, D, is in the spherical portion, and therefore far removed from the walls. On passing the current the screen D in the globe shows a narrow sharp streak of phosphorescence, proving that here the molecules are free to follow their normal course straight from the negative pole. In the cylindrical part of the tube, however, so great is the attraction of the walls that the molecular stream is widened out sufficiently to make the whole surface of the screen, C, glow with phosphorescent light.

If an idle pole, C, C, Fig. 12 (P = 0·0001 mm. or 0·13 M), protected all but the point by a thick coating of glass, is brought into the centre of the molecular stream in front of the negative pole A, and the whole of the inside and outside of the tube walls are coated with metal, D, D, and "earthed," so as to carry away the positive electricity as rapidly as possible, then it is seen that the molecules leaving the negative pole and striking upon the idle pole C on their journey along the tube carry a negative charge, and communicate negative electricity to the idle pole.

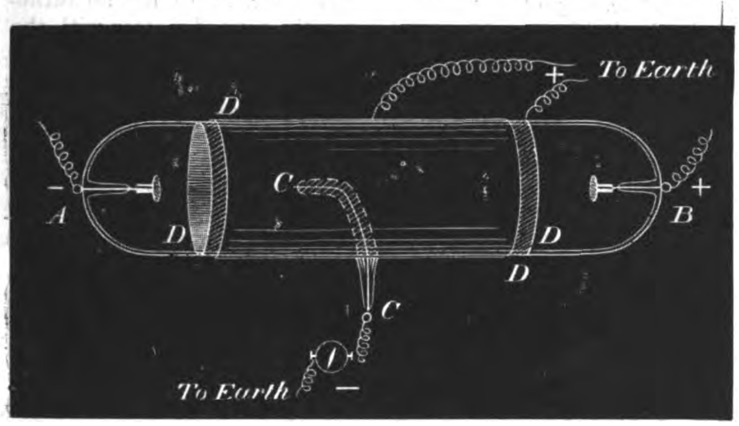

Fig. 12.—Pressure = ·0001 mm. = ·13 M.

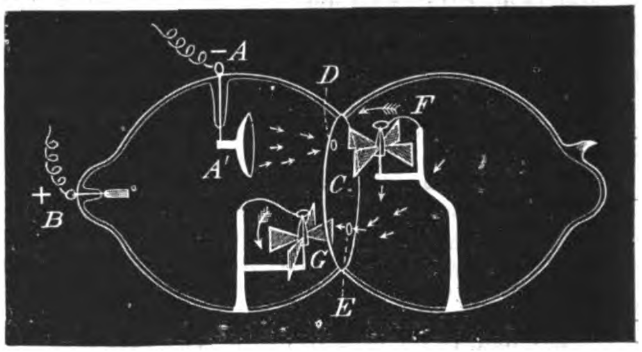

Fig. 14.—Pressure = .001 mm. = 1·3 M.

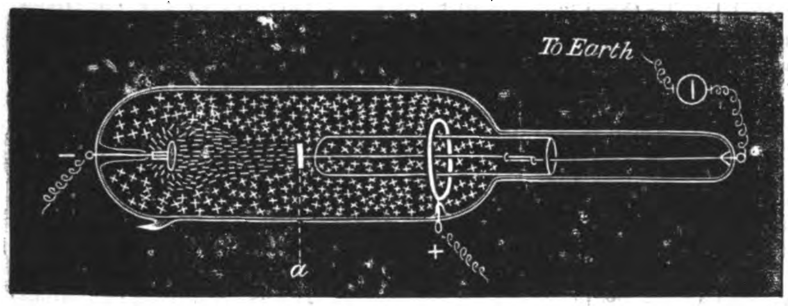

Fig. 13A.—Pressure = ·0001 mm. = ·13 M.

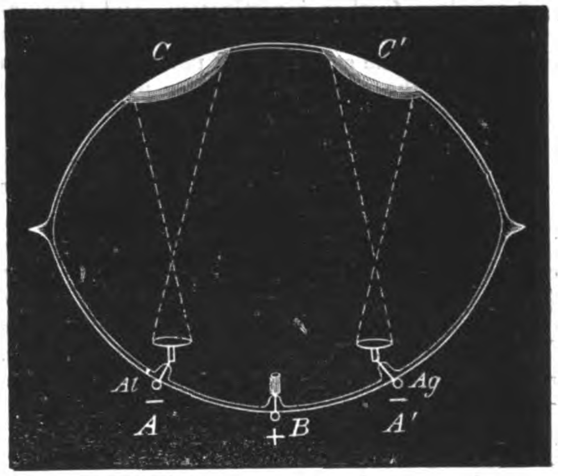

Fig. 15.—Pressure = ·00068 mm. = ·9 M.

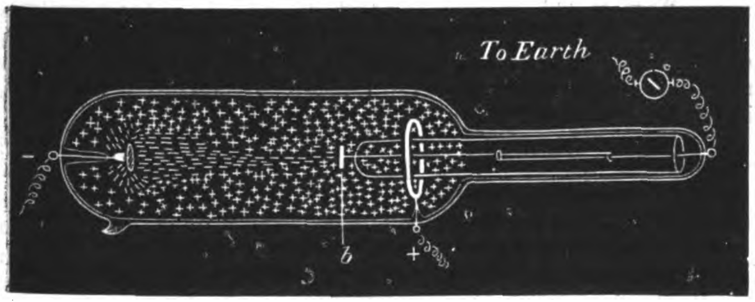

Fig. 13B.—Pressure = ·0001 mm. = ·13 M.

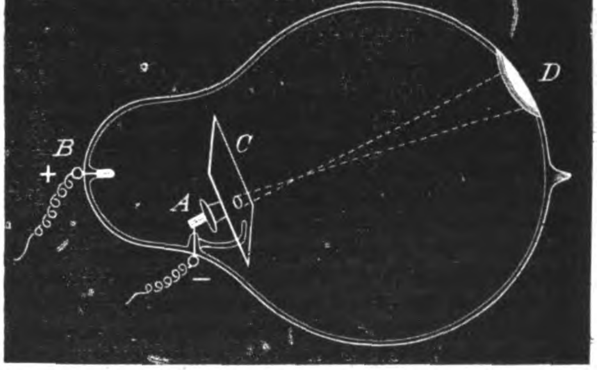

Fig. 16.—Pressure = ·00068 mm. = ·9 M.

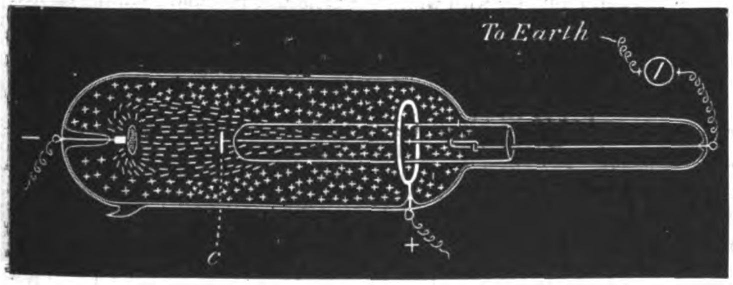

Fig. 13c.—Pressure = ·0001 mm. = ·13 M.

This tube is of interest since it is the one in which I was first able to perceive how in my earlier results I always obtained a positive charge from an idle pole placed in the direct stream from the negative pole. Having got so far, it was easy to devise a form of apparatus that completely verified the theory, and at the same time threw considerably more light upon the subject. Fig. 13, *a*, *b*, *c*, is such a tube, and in

Digitized by Google

this model I have endeavoured to show the electrical state of it at a high vacuum by marking a number of + and − signs. The exhaustion has been carried to 0·0001 mm. or 0·13 M, and you see that in the neighbourhood of the positive pole and extending almost to the negative, the tube is strongly electrified with positive electricity, the negative atoms shooting out from the negative pole in a rapidly diminishing cone. If an idle pole is placed in the position shown at Fig. 13, *a*, the impacts of positive and negative molecules are about equal and no decided current will pass from it through the galvanometer to earth. This is the *neutral* point. But if we imagine the idle pole to be as at Fig. 13, *b*, then the positively electrified molecules greatly preponderate over the negative molecules, and positive electricity is shown. If the idle pole is now shifted, as shown at Fig. 13, *c*, the negative molecules preponderate, and the pole will give negative electricity.

As the exhaustion proceeds. the positive charge in the tube increases, and the neutral point approaches closer to the negative pole, and at a point just short of non-conduction so greatly does the positive electrification preponderate that it is almost impossible to get negative electricity from the idle pole, unless it actually touches the negative pole. This tube is before you, and I will now proceed to show the change in direction of current by moving the idle pole.

I have not succeeded in getting the "Edison" current n incandescent lamps to change in direction at even the highes degree of exhaustion which my pump will produce. The subject requires further investigation, and like other residual phenomena these discrepancies promise a rich harvest of future discoveries to the experimental philosopher, just as the waste products of the chemist have often proved the source of new and valuable bodies.

*Properties of Radiant Matter.*

One of the most characteristic attributes of radiant matter —whence its name—is that it moves in approximately straight lines and in a direction almost normal to the surface of the electrode. If we keep the induction current passing continuously through a vacuum tube in the same direction, we can imagine two ways in which the action proceeds; either the supply of gaseous molecules at the surface of the negative pole must run short, and the phenomena come to an end, or the molecules must find some means of getting back. I will show you an experiment which reveals the molecules in the very act of returning. Here is a tube (Fig. 14) exhausted to a pressure of 0·001 mm. or 1·3 M. In the middle of the tube is a thin glass diaphragm, C, pierced with two holes, D and E. At one part of the tube a concave pole, A′, is focussed on the upper hole, D, in the diaphragm. Behind the upper hole and in front of the lower one, are movable vanes, F and G, capable of rotation by the slightest current of gas through the holes.

On passing the current with the concave pole negative, the small vanes rotate in such a manner as to prove that at this high exhaustion a stream of molecules issues from the lower hole in the diaphragm, whilst at the same time a stream of freshly charged molecules is forced by the negative pole through the upper hole. The experiment speaks for itself, showing as forcibly as an experiment can show that so far the theory is right.

This view of the ultra-gaseous state of matter is advanced merely as a working hypothesis, which, in the present state of our knowledge, may be regarded as a necessary help to be retained only so long as it proves useful. In experimental research early hypotheses have necessarily to be modified, or adjusted, or perhaps entirely abandoned, in deference to more accurate observations. Dumas said, truly, that hypotheses were like crutches which we throw away when we are able to walk without them.

*Radiant Matter and "Radiant Electrode Matter."*

In recording my investigations on the subject of radiant matter and the state of gaseous residues in high vacua under electrical strain, I must refer to certain attacks on the views I have propounded. The most important of these questionings are contained in a volume of "Physical Memoirs," selected and translated from foreign sources under the direction of the Physical Society (Vol. I., Part 2). This volume contains two memoirs, one by Hittorff on the "Conduction of Electricity in Gases," and the other by Puluj on "Radiant Electrode Matter and the So-called Fourth State." Dr. Puluj's Paper concerns me most, as the author has set himself vigorously to the task of opposing my conclusions. Apart from my desire to keep controversial matter out of an address of this sort, time would not permit me to discuss the points raised by my critic; I will, herefore, only observe in passing that Dr. Puluj has no authority for linking my theory of a fourth state of matter with the highly transcendental doctrine of four dimensional space.

Reference has already been made to the mistaken supposition that I have pronounced the thickness of the dark space in a highly-exhausted tube, through which an induction spark is passed, to be identical with the natural mean free path of the molecules of gas at that exhaustion. I could quote numerons passages from my writings to show that what I meant and said was the mean free path as amplified and modified by the electification.* In this view I am supported by Prof. Schuster,† who in a passage quoted below distinctly admits that the mean free path of an electrified molecule may differ from that of one in its ordinary state.

The great difference between Puluj and me lies in his statement that‡ "*the matter which fills the dark space consists of mechanically detached particles of the electrodes which are charged with statical negative electricity, and move progressively in a straight direction.*"

To these mechanically detached particles of the electrodes, "of different sizes, often large lumps," § Puluj attributes all the phenomena of heat, force, and phosphorescence that I from time to time have described in my several Papers.

Puluj objects energetically to my definition "Radiant Matter," and then proposes in its stead the misleading term, "Radiant Electrode Matter." I say "misleading," for while both his and my definitions equally admit the existence of "Radiant Matter," he drags in the hypothesis that the radiant matter is actually the disintegrated material of the poles.

Puluj declares that the phenomena I have described in high vacua are produced by his irregularly shaped lumps of Radiant Electrode Matter. My contention is that they are produced by Radiant Matter of the residual molecules of gas.

Were it not that in this case we can turn to experimental evidence I would not mention the subject to you. On such an occasion as this controversial matter must have no place; therefore I content myself, at present, by showing a few novel experiments which demonstratively prove my case.

Let me first deal with the Radiant Electrode hypothesis. Some metals, it is well known, such as silver, gold, or platinum, when used for the negative electrode in a vacuum tube, volatilise more or less rapidly, coating any object in their neigh-

* "The thickness of the dark space surrounding the negative pole is the measure of the mean length of the path of the gaseous molecules between successive collisions. The electrified molecules are projected from the negative pole with enormous velocity, varying, however, with the degree of exhaustion and intensity of the induction current."—(*Phil. Trans.*, Part I., 1879, par. 530.)

"The extra velocity with which the molecules rebound from the excited negative pole keeps back the more slowly moving molecules which are advancing towards the pole. The conflict occurs at the boundary of the dark space, where the luminous margin bears witness to the energy of the discharge."—(*Phil. Trans.*, Part I., 1879, par. 507.)

"Here, then, we see the induction spark actually illuminating the lines of molecular pressure caused by the excitement of the negative pole."—(R. I. Lecture, Friday, April 4, 1879.)

"The electrically excited negative pole supplies the *force majeure* which entirely, or partially, changes into a rectilinear action the irregular vibration in all directions."—(*Proc. Roy. Soc.* 1880, page 472.)

"It is also probable that the absolute velocity of the molecules is increased so as to make the mean velocity with which they leave the negative pole greater than that of ordinary gaseous molecules."—(*Phil. Trans.*, Part II., 1881, par. 719.)

† "It has been suggested that the extent of the dark space represents the mean free path of the molecules. . . . It has been pointed out by others that the extent of the dark space is really considerably greater than the mean free path of the molecules, calculated according to the ordinary way. My measurements make it nearly twenty times as great. This, however, is not in itself a fatal objection; for, as we have seen, the mean free path of an ion may be different from that of a molecule moving among others."—Schuster, *Proc.* Roy. Soc., XLVII., pp. 556-7.

‡ "Physical Memoirs," Part 2, Vol. I., p. 244. The paragraph is italicised in the original.

bourhood with a very even film. On this depends the well-known method of electrically preparing small mirrors, &c. Aluminium, however, seems exempt from this volatility. Hence, and for other reasons, it is generally use for electrodes.

If, then, the phenomena in a high vacuum are due to the "electrode matter," the more volatile the metal used the greater should be the effect.*

Here is a tube (Fig. 15, P. = 0·00068mm., or 0·9 M.), with two negative electrodes, A, A′, so placed as to project two luminous spots on the phosphorescent glass of the tube. One electrode, A′, is of pure silver, a volatile metal; the other, A, is of aluminium, practically non-volatile. A quantity of "electrode matter" will be shot off from the silver pole, and practically none from the aluminium pole; but you see that in each case the phosphorescence, C, C′, is identical. Had the Radiant Electrode matter been the active agent, the more intense phosphorescence would proceed from the more volatile pole.

A drawing of another experimental piece of apparatus is shown in Fig. 16. A pear-shaped bulb of German glass has near the small end an inner concave negative pole, A, of pure silver so mounted that its inverted image is thrown upon the opposite end of the tube. In front of this pole is a screen of mica, C, having a small hole in the centre, so that only a narrow pencil of rays from the silver pole can pass through, forming a bright spot, D, at the far end of the bulb. The exhaustion is about the same as in the previous tube, and the current has been allowed to pass continuously for many hours so as to drive off a certain portion of the silver electrode, and upon examination it is found that the silver has all been deposited in the immediate neighbourhood of the pole, whilst the spot, D, at the far end of the tube that has been continuously glowing with phosphorescent light is practically free from silver.

The experiment is too lengthy for me to repeat it here, so I shall not attempt it, but I have on the table the results for examination.

The identity of action of silver and aluminium in the first case, and the non-projection of silver in this second instance, in themselves are sufficient to condemn Dr. Puluj's hypothesis, since they prove that phosphorescence is independent of the material of the negative electrode. In front of me is a set of tubes that to my mind puts the matter wholly beyond doubt. The tubes contain no inside electrodes with the residual gaseous molecules, and with them I will proceed to give some of the most striking radiant matter experiments without any inner metallic poles at all.

In all these tubes the electrodes, which are of silver, are on the outside, the current acting through the body of the glass. The first tube contains gas only slightly rarefied and at the stratification stage. It is simply a closed glass cylinder, with a coat of silver deposited outside at each end, and exhausted to a pressure of 2 mm. The outline of the tube is shown in Fig. 17. I pass a current and, as you see, the stratifications, though faint, are perfectly formed.

The next tube, seen in outline in Fig. 18, shows the dark space. Like the first it is a closed cylinder of glass, with a central indentation forming a kind of hanging pocket, and almost dividing the tube into two compartments. This pocket, silvered on the air side, forms a hollow glass diaphragm that can be connected electrically from the outside, forming the negative pole, A; the two ends of the tube, also outwardly silvered, form the positive poles, B B. I pass the current and you all see the dark space distinctly visible. The pressure here is 0·076 mm., or 100 M. The next stage, dealing with more rarefied matter, is that of phosphorescence. Here is an egg-shaped bulb, shown in Fig. 19, containing some pure yttria, and a few rough rubies. The positive electrode, B, is on the bottom of the tube under the phosphorescent material; the negative, A, is on the upper part of the tube. See how well the rubies and yttria phosphorescence under molecular bombardment, at an internal pressure of 0·00068 mm., or 0·9 M.

A shadow of an object inside a bulb can also be projected on to the opposite wall of the bulb by means of an outside pole. A mica cross is supported in the middle of the bulb (Fig. 20), and on connecting a small silvered patch, A, on one side of the bulb with the negative pole of the induction coil, and putting the positive pole to another patch of silver, B, at the top, the opposite side of the bulb glows with a phosphorescent light, on which the black shadow of the cross seems sharply cut out. Here the internal pressure is 0·00068 mm., or 0.9 M.

Passing to the next phenomenon, I proceed to show the production of mechanical energy in a tube without internal poles. It is shown in Fig. 21 (P. = 0·001 mm., or 1·3 M.). It contains a light wheel of aluminium, carrying vanes of transparent mica, the poles, A, B, being in such a position outside that the molecular focus falls upon the vanes on one side only. The bulb is placed in the lantern, and the image is projected on the screen; if I now pass the current you see the wheel rotates rapidly, reversing in direction as I reverse the current.

Here is an apparatus (Fig. 22) which shows that the residual gaseous molecules when brought to a focus produce heat. It consists of a glass tube with a bulb blown at one end and a small bundle of carbon wool, C, fixed in the centre, and exhausted to pressure of 0·000076 mm., or 0·1 M. The negative electrode, A, is formed by coating part of the outside of the bulb with silver, and it is in such a position that the focus of rays falls upon the carbon wool. The positive electrode, B, is an outer coating at the other end of the tube. I pass the current, and those who are close may see the bright sparks of carbon raised to incandescence by the impact of the molecular stream.

You thus have seen that all the old "radiant matter" effects can be produced in tubes containing no metallic electrodes to volatilise. It may be suggested that the sides of the tube in contact with the outside poles become electrodes in this case, and that particles of the glass itself may be torn off and projected across and so produce the effects. This is a strong argument, which fortunately can be tested by experiment. In the case of this tube (Fig 23, P = 0·00068 mm, or 0·9 M) the bulb is made of lead glass phosphorescing blue under molecular bombardment. Inside the bulb, completely covering the part that would form the negative pole, A, I have painted a substantial coat of yttria so as to interpose a layer of this earth between the glass and the inside of the tube. The negative and positive poles are silver discs on the outside of the bulb, A being the negative and B the positive poles. If, therefore, particles are torn off and projected across the tube to cause phosphorescence, these particles will not be particles of glass but of yttria, and the spot of phosphorescent light, C, on the opposite side of the bulb, will not be the dull blue of lead glass, but the golden yellow of yttria. You see there is no such indication; the glass phosphoresces with its usual blue glow, and there is no evidence that a single particle of yttria is striking it.

Witnessing these effects I think you will agree I am justified in adhering to my original theory that the phenomena are caused by the radiant matter of the residual gaseous molecules, and certainly not by the torn off particles of the negative electrode.

*Phosphorescence in High Vacua.*

I have already pointed out that the molecular motions rendered visible in a vacuum tube are not the motions of molecules under ordinary condition, but are compounded of these ordinary or kinetic motions and the extra motion due to the electrical impetus.

Experiments show that in such tubes a few molecules may traverse more than a hundred times the *mean* free path, with a a correspondingly increased velocity, until they are arrested by collisions. Indeed, the molecular free path may vary in one and the same tube, and at one and the same degree of exhaustion.

Very many bodies, such as ruby, diamond, emerald, alumina, yttria, samaria, and a large class of earthy oxides and sulphides, phosphorescence in vacuum tubes when placed in the path of the stream of electrified molecules proceeding from the negative

* In a valuable Paper read before the Royal Society, November 20, 1890, by Profs. Liveing and Dewar, on finely-divided metallic dust thrown off the surface of various electrodes in vacuum tubes, they find not only that dust, however fine, suspended in a gas will not act like gaseous matter in becoming luminous with its characteristic spectrum in an electric discharge, but that it is driven with extraordinary rapidity out of the course of the discharge.

Digitized by Google

pole. The composition of the gaseous residue present does not affect phosphorescence; thus, the earth yttria phosphorescences well in the residual vacua of atmospherical air, of oxygen, nitrogen, carbonic anhydride hydrogen, iodine, sulphur, and mercury.

With yttria in a vacuum tube, the point of maximum phosphorescence, as I have already pointed out, lies on the margin of the dark space. The diagram (Fig. 24) shows approximately the degree of phosphorescence in different parts of a tube at an internal pressure of 0·25mm., or 330 M. On the top you see the positive and negative poles, A and B, the latter having the outline of the dark space shown by a dotted line, C. The curve D, E, F, shows the relative intensities of the phosphorescence at different distances from the negative pole, and the position inside the dark space at which phosphorescence does not occur. The height of the curve represents the degree of phospherescence. The most decisive effects of phosphorescence are reached by making the tube so large that the walls are outside the dark space, whilst the material submitted to experiment is placed just at the edge of the dark space.

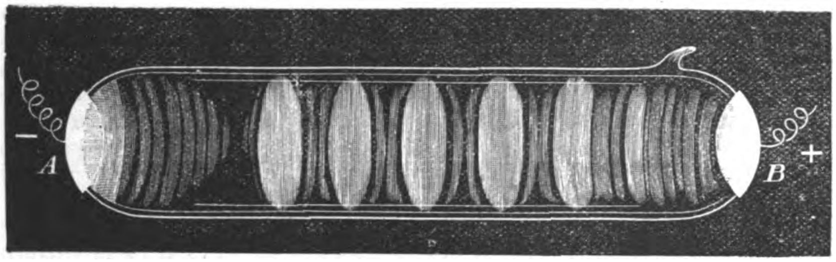

FIG. 17.—Pressure=2· mm.

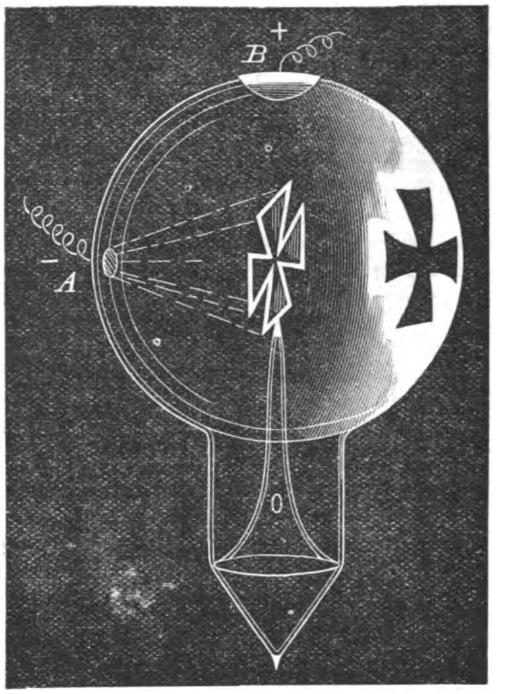

FIG. 20.—Pressure=·00068 mm.=·9 M.

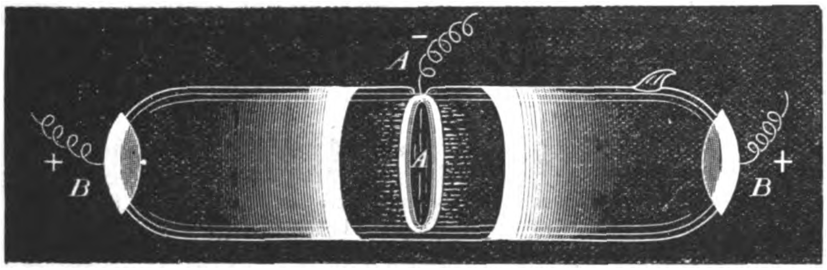

FIG 18.—Pressure= ·076 mm=100·M.

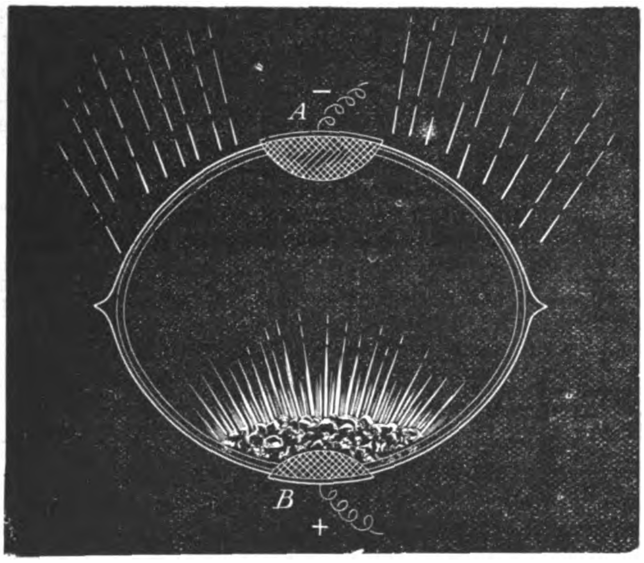

FIG. 19.—Pressure=·00068 mm=·9M.

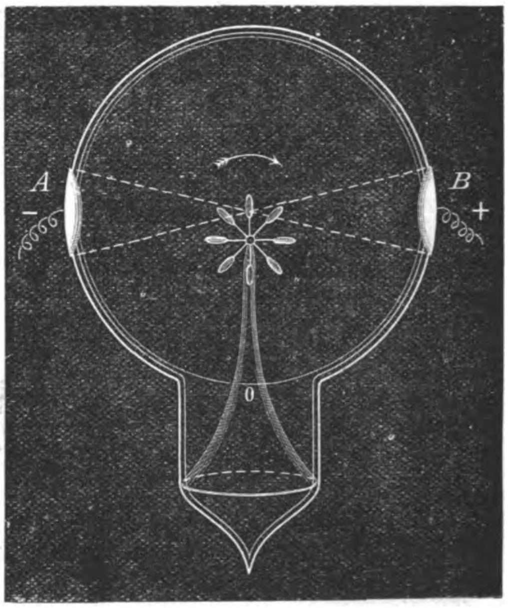

FIG, 21.—Pressure=·001 mm.=1·3 M.

Hitherto I have spoken only of phosphorescence of substances placed under the negative pole. But from numerous experiments I find that bodies will phosphoresce in actual contact with the negative pole.

This is only a temporary phenomenon, and ceases entirely when the exhaustion is pushed to a very high point. The experiment is one scarcely possible to exhibit to an audience, so I must content myself with describing it. A U-tube, shown in Fig. 25, has a flat aluminium pole, in the form of a disc, at each end, both coated with a paint of phosphorescent yttria. As the rarefaction approaches about 0·5 mm. the surface of the negative pole A becomes faintly phosphorescent. On continuing the exhaustion this luminosity rapidly diminishes, not only in intensity but in extent, contracting more and more from the edge of the disc, until ultimately it is visible only as a bright spot in the centre. This fact does not prop a recent theory, that as the exhaustion gets higher the discharge leaves the centre of the pole, and takes place only between the edge and the walls of the tube.

Digitized by Google

If the exhaustion is further pushed, then at the point where the surface of the negative pole ceases to be luminous, the material on the positive pole, B, commences to phosphoresce, increasing in intensity until the tube refuses to conduct, its greatest brilliancy being just short of this degree of exhaustion. The probable explanation is that the vagrant molecules I introduce in the next experiment, happening to come within the sphere of influence of the positive pole, rush violently to it and excite phosphorescence in the yttria, whilst losing their negative charge.

A C B is a U-shaped tube with terminals, A and B, at each end; D and E are two mica screens covered with a phosphorescent powder, having at F and G other screens with a small slit in front, so as to allow only a narrow beam of charged molecules to pass through. At first the tube is exhausted to a pressure of 0·076 mm. or 100 M., and you see how sharp and slightly divergent is the luminous image on screen D, whilst not a trace of phosphorescence is to be seen on the screen E in the other limb of the tube. Now I

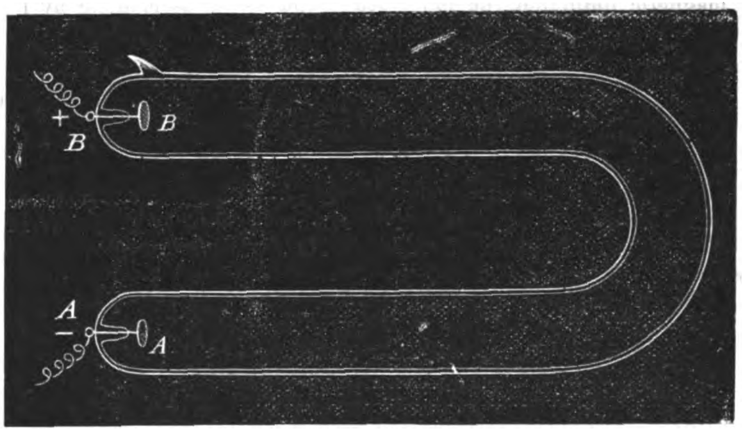

FIG. 25.

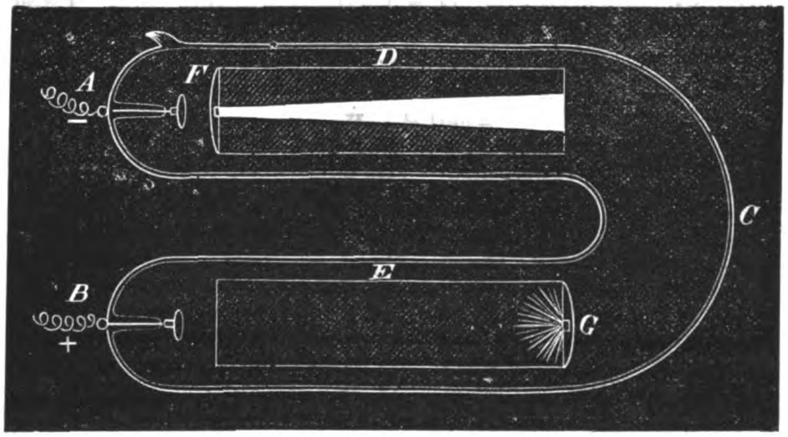

FIG. 26.—Pressure = ·076 mm. = 100 M.

*Loose and Erratic Molecules.*

In the brief time left to me this evening I cannot touch upon the mass of experiments made to render this result clear, so I will at once show you a piece of apparatus that clearly illustrates the cause of phosphorescence at the positive pole. A drawing of this tube is shown at Fig. 26, but let me first explain the effect I expect to obtain, and then endeavour to show the actual experiment.

push the exhaustion to the highest point short of non-conduction (0·000076 mm., or 0·1 M.), and the phenomena change. The initial line of light on D becomes wider and unsteady, whilst at the gate, G, a decided phosphorescence is observable entering the second screen, E. This luminosity diverges to a considerable extent, much more than did the stream of charged molecules observed in the first limb of the

Digitized by Google

tube at the lower exhaustion. This is only to be expected, inasmuch as those sparse molecules which have run the gauntlet of the crowd and have been hunted and buffeted round the corner will have little or no lateral support, but wander to the furthest part of the tube, and altogether behave differently to the orderly procession of molecules at more moderate exhaustion.

(*To be continued.*)

## THE ROTATIONAL ETHER IN ITS APPLICATION TO ELECTRO-MAGNETISM.

BY OLIVER HEAVISIDE.

According to Maxwell's theory of electric displacement, disturbances in the electric displacement and magnetic induction are propagated in a non-conducting dielectric, after the manner of motions in an incompressible solid. The subject is somewhat obscured in Maxwell's treatise by his equations of propagation containing **A**, Ψ, and J, all of which are functions considerably remote from the vectors which represent the state of the field, viz., the electric and magnetic forces, and by some dubious reasoning concerning Ψ and J. There is, however, no doubt about the statement with which I commenced, as it becomes immediately evident when we ignore the potentials and use **E** or **H** instead, the electric or the magnetic force.

The analogy has been made use of in more ways than one, and can be used in very many ways. The easiest of all is to assume that the magnetic force is the velocity of the medium, magnetic induction the momentum, and so on, as is done by Prof. Lodge (Appendix to "Modern Views of Electricity"). I have also used this method for private purposes, on account of the facility with which electro-magnetic problems may be made elastic-solid problems. I have shown that when impressed electric force acts it is the curl or rotation of the electric force which is to be considered as the source of the resulting disturbances. Now, on the assumption that the magnetic force is the velocity in the elastic-solid, we find that the curl of the impressed electric force is represented simply by impressed mechanical force of the ordinary Newtonian type. This is very convenient.

But the difficulties in the way of a complete and satisfactory representation of electro-magnetic phenomena by an elastic-solid ether are insuperable. Recognising this, Sir W. Thomson has recently brought out a new ether; a rotational ether. It is incompressible, and has no true rigidity, but possesses a quasi-rigidity arising from elastic resistance to absolute rotation.

The stress consists partly of a hydrostatic pressure (which I shall ignore later), but there is no distorting stress, and its place is taken by a rotating stress. It gives rise to a translational force and a torque. If **E** be the torque, the stress on any plane **N** (unit normal) is simply **VEN**, the vector product of the torque and the normal vector.

The force is − curl **E**. We have therefore the equation of motion

$$-\,\text{curl}\,\mathbf{E} = \mu\dot{\mathbf{H}},$$

if **H** is the velocity and $\mu$ the density. But, alas, the torque is proportional to the rotation. This gives

$$\text{curl}\,\mathbf{H} = c\dot{\mathbf{E}},$$

where $c$ is the compliancy, the reciprocal of the quasi-rigidity.

Now these are the equations connecting electric and magnetic force in a non-conducting dielectric, when $\mu$ is the inductivity and $c$ the permittancy. We have a parallelism in detail, not merely in some particulars. The kinetic energy $\frac{1}{2}\mu H^2$ represents the magnetic energy, and the potential energy $\frac{1}{2}cE^2$ the electric energy. The vector-flux of energy is **VEH**, the activity of the stress.

This mode of representation differs from that of Sir W. Thomson, who represents magnetic force by rotation. This system makes electric energy kinetic, and magnetic energy potential, which I do not find so easy to follow.

Now let us, if possible, extend our analogy to conductors. Let the translational and the rotational motions be both frictionally resisted, and let the above equations become

$$-\,\text{curl}\,\mathbf{E} = g\mathbf{H} + \mu\dot{\mathbf{H}},$$
$$\text{curl}\,\mathbf{H} = k\mathbf{E} + c\dot{\mathbf{E}},$$

where $g$ is the translational frictionality; $k$ will be considered later. We have now the equations of electric and magnetic force in a dielectric with duplex conductivity, $k$ being the electric and $g$ the magnetic conductivity (by analogy with electric force, but a frictionality in our present dynamical analogy).

We have, therefore, still a parallelism in every detail. We have waste of energy by friction $gH^2$ (translational) and $kE^2$ (rotational). If $g/\mu = k/c$ the propagation of disturbances will take place precisely as in a non-conducting dielectric, though with attenuation caused by the loss of energy.

To show how this analogy works out in practice, consider a telegraph circuit, which is most simply taken to be three co-axial tubes. Let, A, B, and C be the tubes; A the innermost, C the outermost, B between them; all closely fitted. Let their material be the rotational ether. In the first place, suppose that there is perfect slip between B and its neighbours. Then, when a torque is applied to the end of B (the axis of torque to be that of the tubes), and circular motion thus given to B, the motion is (in virtue of the perfect slip) transmitted along B, without change of type, at constant speed, and without affecting A and C.

This is the analogue of a concentric cable, if the conductors A and C be perfect conductors, and the dielectric B a perfect insulator. The terminal torque corresponds to the impressed voltage. It should be so distributed over the end of B that the applied force there is circular tangential traction, varying inversely as the distance from the axis; like the distribution of magnetic force, in fact.

Now, if we introduce translational and rotational resistance in B, in the above manner, still keeping the slip perfect, we make the dielectric not only conducting electrically but also magnetically. This will not do. Abolish the translational resistance in B altogether, and let there be no slip at all between B and A, and B and C. Let also there be rotational resistance in A and C.

We have now the analogue of a real cable: two conductors separated by a third. All are dielectrics, but the middle one should have practically very slight conductivity, so that it is pre-eminently a dielectric; whilst the other two should have very high conductivity, so that they are pre-eminently conductors. The three constants, $\mu$, $c$, $k$, may have any value in the three tubes, but practically $k$ should be in the middle tube a very small fraction of what it is in the others.

It is remarkable that the *quasi-rotational* resistance in A and C should tend to counteract the distorting effect on waves of the *quasi-rotational* resistance in B. But the two rotations, it should be observed, are practically perpendicular, being axial or longitudinal (now) in A and C, and transverse or radial in B; due to the relative smallness of $k$ in the middle tube.

To make this neutralising property work equally, we must transfer the resistance in the tubes A and C to the tube B, at the same time making it translational resistance. Also restore the slip. Then we can have perfect annihilation of distortion in the propagation of disturbances, viz., when $k$ and $g$ are so proportioned as to make the two wastes of energy equal. In the passage of a disturbance along B there is partial absorption, but no reflection.

But as regards the meaning of the above $k$ there is a difficulty. In the original rotational ether the torque varies as the rotation. If we superadd a real frictional resistance to rotation we get an equation of the form

$$\dot{\mathbf{E}} = \left(a + b\frac{d}{dt}\right)\text{curl}\,\mathbf{H},$$

**E** being (as before) the torque, and **H** the velocity. But this is not of the right form, which is (as above)

$$\text{curl}\,\mathbf{H} = \left(k + c\frac{d}{dt}\right)\mathbf{E};$$

therefore some special arrangement is required (to produce the dissipation of energy $k\mathbf{E}^2$), which does not obviously present itself in the mechanics of the rotational ether.

On the other hand, if we follow up the other system, in which magnetic force is allied with rotation, we may put $g = 0$, let − **E** be the velocity and **H** the torque; $\mu$ the compliancy

Digitized by Google

$c$ the density, and $k$ the translational frictionality. This gives

$$-\operatorname{curl}\mathbf{E} = \mu\dot{\mathbf{H}},$$
$$\operatorname{curl}\mathbf{H} = k\mathbf{E} + c\dot{\mathbf{E}}.$$

We thus represent a homogeneous conducting dielectric, with a translational resistance to cause the Joulean waste of energy. But it is now seemingly impossible to properly satisfy the conditions of continuity at the interface of different media. For instance, the velocity − E should be continuous, but we do not have normal continuity of electric force at an interface. In the case of the tubes we avoided this difficulty by having the velocity tangential.

Either way, then, the matter is left, for the present, in an imperfect state.

In the general case, the $d/dt$ of our equations should receive an extended meaning, on account of the translational motion of the medium. The analogy will, therefore, work out less satisfactorily. And it must be remembered that it is only an analogy in virtue of similitude of relations. We cannot, for instance, deduce the Maxwellian stresses and mechanical forces on charged or currented bodies. The similitude does not extend so far. But certainly the new ether goes somewhat further than anything known to me that has been yet proposed in the way of a stressed solid.

## PHYSICAL SOCIETY.

At the meeting of this Society, held on the 16th inst., Prof. G. M. Minchin, M.A., read a Paper entitled

### "Experiments in Photo-electricity."

The author's investigations in Photo-electricity were begun in the year 1877, the object then in view being to endeavour to obtain a solution of the problem of photography at a distance for which he had suggested the name of telephotography.

The author's earliest experiments were made with cells containing strips of silver, as electrodes, coated with collodion or gelatine emulsions of various salts of silver, and also eosine, fluorescine, and some aniline dyes, and immersed in dilute solutions of different salts of sodium, potassium, and barium, and even distilled water, the process being, of course, carried out in darkness. One of the electrodes was completely screened from light, while the other could be illuminated at pleasure. Prior to exposure the electrodes were connected through a Thomson reflecting galvanometer, and the current due to inequality in the plates allowed to subside before exposing to light. On exposing the unscreened electrode to light, a current was set up, the screened electrode being positive in some cases and negative in others, this being determined by the salts employed in constructing the cell. The more highly refrangible rays of the spectrum were found in most of the cells to give the greatest effect, but one in which an emulsion of sulphide of silver and a dilute solution of potassium sulphate was employed was most sensitive to the green rays. When an emulsion of silver bromide and a dilute solution of potassium bromide were used, the effect of passing a current through it from a bichromate cell was found to be a blackening of the immersed portion of the silver electrode connected with the carbon pole, and the immersed portion of the other electrode, though not visibly affected by the current, was turned black by means of the ordinary pyrogallic acid developing solution. Similar results were obtained when a photo-electric cell was employed in place of the bichromate cell.

Some extremely interesting results, however, were obtained with electrodes of ordinary commercial tinfoil, unprepared in any way, immersed either in ordinary tap water or in distilled water. The exposed electrode always became initially positive, but after an interval of time, ranging from a few minutes to some hours, the current was reversed in direction and of greater strength than before, and continued for many days if the exposure to light was maintained. When the surface of the tinfoil was chemically cleaned the cells became completely insensitive to light, showing that the photo-electric effects must be due to the presence of a film of some kind on the surface of the foil.

After a long series of experiments, in which an electrometer was used instead of the galvanometer, the author discovered that a sensitive surface which at once became negative on exposure to light could be obtained by coating the tinfoil with sulphide of tin, and the liquid which gave the greatest sensitiveness was methyl alcohol, prepared from oil of wintergreen. The author then described a method at which he had arrived, after a laborious series of experiments, for producing a sensitive surface, which will become positive on exposure to light. The residual effect after exposure to light takes a considerable time to disappear, but it can be rapidly got rid of by connecting the sensitive electrode with the copper, and the insensitive electrode with the zinc of a Daniell's cell. The volts developed were found to be approximately proportional to the square root of the intensity of the incident light.

One of the most curious effects observed with these cells is that after standing for some time they frequently become insensitive, and the cell can be restored to its full original sensitiveness by a slight tap to its support, or to the table on which it stands. When in the sensitive state a similar tap renders the cells insensitive, and this series of alternating sensitiveness and insensitiveness can be continued indefinitely. Cells in the insensitive state may also be made sensitive by electric sparking in their neighbourhood.

The deflection on exposure to light was much smaller when the sensitive plate was in connection with the zinc pole of the Daniell than when connected with the copper pole, and the author, in consequence of this, suggests as a possible explanation of the effect of light on the cells, that it may reduce the amount of oxygen on the films, for when the sensitive plate was connected with the copper of the Daniell the amount of oxygen on it would be increased, while it would be diminished when the sensitive electrode was connected with the zinc.

The author then referred to the so-called "selenium cells," which should more properly be termed "selenium conductors," or "selenium resistances." He stated that last year he first endeavoured to construct selenium cells, properly so-called, viz., cells in which an E.M.F. was set up by the action of light. The best effects were produced by means of aluminium electrodes, one of which was coated on one side with selenium and gradually heated until the brown colour had been attained. When, however, the aluminium plates were immersed in alcohol they became covered with a gelatinous deposit which made it necessary to find some other liquid, and after many trials *acetone* was found to give the best results. These cells differ from any of the photo-electric cells previously constructed by the author in their great sensitiveness to the light from all parts of the spectrum, the maximum effect being produced in the yellow bordering on the green.

The author, in conclusion, called attention to three problems, towards the solution of which these photo-electric cells might contribute. The first was the construction of a really scientific photometer, for purposes of comparison at any rate. Each light would be spread out into a spectrum, and the intensities of the different portions compared by means of the cells, the intensities of the different portions being proportional to the squares of the observed volts. The principle of Newton's chromatic circle could then be applied to determine the resultant intensity of the light. The second problem was the photographing of objects at a distance, and it was one which there appeared to be no prospect of solving at present, in spite of the startling stories appearing from time to time in the newspapers. The third problem was the direct transformation of radiant solar energy into useful work.

The discussion of the paper was postponed to the meeting of February 13th, when the author will repeat some of the most interesting experiments.

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**FRIDAY, January 23rd.**

Royal Institution.

*9 p.m.* Evening Discourse: "Some Applications of Photography," by Lord Rayleigh, F.R.S.

**MONDAY January 26th.**

London Chamber of Commerce.

*4 p.m.* Meeting of the Electrical and Allied Trades' Section Committee.

Society of Arts.

*8 p.m.* Cantor Lecture II. 1. "The Construction and Capabilities of Musical Instruments," by A. J. Hipkins, F.S.A.

**TUESDAY, January 27th.**

Institution of Civil Engineers.

*8 p.m.* Ordinary Meeting. Paper to be read with a view to discussion: "Machine Stoking," by J. Fred. Spencer, M.I.C.E.

Society of Arts.

*8 p.m.* Applied Art Section. Paper to be read: "Lithography: a Finished Chapter of Illustrative Art," by William Simpson.

**WEDNESDAY. January 28th.**

Society of Arts.

*8 p.m.* Ordinary Meeting. Paper to be read: "Illustrated Journalism," by Carmichael Thomas.

Institution of Mechanical Engineers.

*7.30 p.m.* Annual General Meeting. Election of Officers. After which the following Papers will be read and discussed, as far as time permits:—"On some Different Forms of Gas Furnaces," by Bernard Dawson; "On the Mechanical Treatment of Moulding Sand," by Walter Bagshaw; Fourth Report of the Research Committee on Friction; Experiments on the Friction of a Pivot Bearing.

# The Electrician.

**Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny**
**Editorial, Publishing, and Printing Offices:**
**SALISBURY COURT, FLEET ST., LONDON, E.C.**
*Telephone No.* 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

*All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "*THE ELECTRICIAN,*" Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "*THE ELECTRICIAN*" Printing and Publishing Company, Limited, and be crossed "Coutts and Co." All other letters to be addressed to the Editor.*

*All letters intended for insertion in "*THE ELECTRICIAN,*" or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

*"*THE ELECTRICIAN*" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

*"*THE ELECTRICIAN*" is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

*New Volumes of "*THE ELECTRICIAN*" commence in May and November.*

## SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

| | 3 months. s. d. | 6 months. s. d. | 12 months. s. d. |
|---|---|---|---|
| For the United Kingdom | 5 0 | 10 0 | 19 6 |
| For Foreign Parts and Colonies:— | | | |
| Within Postal Union | 6 6 | 12 6 | 24 0 |
| Aden Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar | 7 6 | 14 6 | 28 0 |

## TO ADVERTISERS.

*"*THE ELECTRICIAN*" offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

*Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xvii.) are accepted up to 4 p.m. on Thursday.*

## TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

## "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

*Early in each year is issued "*THE ELECTRICIAN*" *ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consisted of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

*The 1891 Edition is now actively preparing, and Subscription and Advertisement Orders, New Names, Corrections, &c., can be received.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

*All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "*THE ELECTRICIAN*" Printing and Publishing Company, who are proprietors of the well-known "*ELECTRICIAN*" Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

## MECHANICAL EQUIVALENTS IN PATENT LAW.

It may safely be said that until the passing of the Electric Lighting Act of 1888, more money changed hands in connection with electrical patents than was made in legitimate electrical trading. Under the more healthy conditions and sound work of to-day patents are but means, and subordinate means, to an end; and not being so frequently bought and sold they are not so often produced for that purpose. But patents and patent rights, representing as they do an important a portion of the invested capital of many companies, and forming in many cases the acquired capital of so many individuals, are of weighty interest to the electrical profession. Scores of electrical engineers have acquired sufficient knowledge of patent law to draw up very fair specifications, and many of the lesser patent agents seem to expect of their electrical clients, if not a ready-made draft specification, at all events a document which needs but little re-modelling. This being so, patent cases of a typical character, especially if they be not too protracted, are of considerable interest, since from the arguments and judgments may be gleaned a knowledge of the important points with far less labour than from a dry treatise on the subject.

Without wishing to encourage amateur specification-drawing, we would remark that the gist of the subject lies in the proper appreciation of what can, and what cannot be patented; and the chief points in which a patent is liable to be bad. It is hardly fair to divide these into intentional and unintentional cases, but of the former, an infringement by a "colourable imitation" may be taken as an example, while an invalidation by prior publication is an instance of the latter. Since an idea or a principle cannot be protected by a patent, but only the method by which it can be carried out in practice, the inventor either describes and claims as many different methods as he can think of, or divides them into several different patents, so that if one is faulty the others

Digitized by Google

will still be valid. Then when his invention turns out to be a good thing, and attracts the attention of other workers, they cannot be blamed if they discover some other device which the inventor overlooked, and though the credit of the idea or principle may be his, their more perfected arrangements may perhaps supplant the less mature designs of the original patentee. But of another class are they whose ingenuity is directed, not to new methods, but to close imitations of those which have proved to be successful. Of these colourable imitations, one of the most common is that in which the result achieved by the original invention is arrived at by a slightly altered arrangement of parts. Had Mr. MORDEY done nothing more than build a FERRANTI dynamo with a fixed armature and revolving magnets, it would probably have been held that such a machine was an infringement of FERRANTI'S patent, since the dynamical action and the electrical result would have been identical, with the sole advantage of dispensing with collecting brushes. Mr. MORDEY, as all the world knows, did something very different from this, as he marvellously simplified the field-magnet part, and cheapened its construction.

One man may take the invention of another, as, for example, BINNS' knot-tying mechanism, which was patented for tying warps for weaving, and may apply it to sheaf binding, if the inventor only specified that one purpose of tying warps. While some machines, depending merely on the relative motion of two parts, as in a dynamo or a coffee mill, will produce exactly the same results if the moving part be fixed and the stationary part be moved, there are obviously many machines in which such an interchange would be absurd and would give no result whatever, as, for example, a MORSE sounder with an armature fixed and with the magnet and its attachments free to move. A great number of cases have been decided upon the question of mechanical equivalents, such as the well-known PROCTER v. BENNIS, where a mechanical stoker with a coal spreader keyed on a moving shaft was imitated by a similar spreader swung upon a fixed pin. On the other hand, there is the classical example of WATT'S sun-and-planet motion, which he devised (though in one sense a mere mechanical equivalent) in order to avoid the use of the crank, which, though his own invention, had been patented by one of his own employés.

In approaching the question whether a device is a mechanical equivalent in the sense in which such would constitute an infringement of a patent, the first thing to examine is the result intended, next the method, and lastly the means employed. At first sight it certainly appeared, during the patent case tried last week, that to rotate a frame containing hides in a stationary vat, or to cause the vat to rotate while the frame was fixed, was very similar to the modified arrangement of the coffee mill or the dynamo to which we have alluded; and curiously enough, the relative movements in the two cases are closely comparable, though the result would be totally different. In the latter arrangement the bulk of the liquor would remain stationary, and that very part would rotate which in the former and practical arrangement is retarded, the cause in each case being the skin friction of the sides of the vat. In a case cited last week, woollen goods were finished by pressing between hot metal surfaces. In one patent these were flat, and were moved by screws or hydraulic pressure, and in another, hot rollers were used, and it was decided that there was no infringement. Here the results were the same, and the method, that is the use of hot metal surfaces, was the same, but the means were different.

There have been cases where owing to an extraordinary comprehensiveness of definition it has been impossible for any intending competitors to avoid the use of means which might be held to be mechanical equivalents of an important part of an invention. In the telephone transmitter patent the well known combination of parts called a microphone were made to vibrate by means of a diaphragm, and so wide did the definition of a diaphragm become that it eventually embraced everything by which a microphone could be set in vibration. Patentees who are ambitious and desire to have a far-reaching patent would do well to forsake the vulgar tongue for any high-sounding terms that they can find when describing their apparatus. A filament of a glow lamp, it has been said, may be as thick as a cow's tail; for if it be long enough to reach to the moon it might fairly be called a filament. It has been cynically remarked that the acme of invention in a patentee is to invent a new name for an old device, and thereby secure a monoply for everything that a benevolent judge can be induced to consider as described by that name. If every carbon wire is to be described as a "filament," and every conceivable vibrating organ a "diaphragm," it is useless to discuss what devices are or could be the respective mechanical equivalents of these things. Equivalence has a different meaning in different departments of science. In one sense the substitution of a solution of chloride of nickel for sulphate of nickel in a process for nickel-plating, is the substitution of a chemically equivalent material. But the chemist would emphatically deny that any chloride can be the equivalent of any sulphate, unless used in certain exact combining proportions. A chemically equivalent quantity is not by any means necessarily an equivalent for the purpose of an industrial process. We could adduce a few instances of what may be called electrical equivalents, but it would be invidious to draw attention to them. The fertility of inventive genius has happily been so great that electrical inventors have managed to keep clear of each other as regards means and method; and this is remarkable since the objects are so few in comparison with the multitude of patents. Enormous numbers of arc lamps have been called forth by an immense amount of mechanical ingenuity, and they can be classified into orders and genera, but there seems to be room for all of them—at least, for all the fairly successful types—without any allegations of infringement.

The able speech of Mr. MOULTON, of which a brief report will be found in another column, dealt most exhaustively with this question, and the case which he thus successfully defended, apart from the legal point relating to the International Convention, was of a very typical character, and one which will take its place among the many instructive decisions of patent law.

## OBITUARY.

### EMILE REYNIER.

We have to record the death of M. Emile N. Reynier at the early age of forty.

M. Reynier was born in Paris on May 17, 1851. He was apprenticed to a tinman in 1865, and to an engineer in 1867. From 1868 to 1875 he was engaged in commercial pursuits, but devoted his leisure to mathematical and scientific studies. In 1875 M. Reynier made his *début* in commercial electricity by his invention of metal-coated carbons for arc lamps. In 1878 he brought out an incandescent lamp which worked in the open air. In 1880 he invented his regenerating alkaline battery, but soon abandoned it in favour of the Faure accumulator, with the inventor of which M. Reynier long worked. From 1881 to 1888 he occupied himself with the question of accumulator traction, a new theory of the chemistry of the storage battery, the propulsion of torpedoes,

Digitized by Google

&c., &c. It was during this period that M. Reynier published his chief works: "Les Piles Electriques et Accumulateurs" (1884), "Les Accumulateurs Electriques" (1885), and the "Traité de l'Accumulateur Voltaïque" (1888), the latter of which is now translated into English. In 1889 M. Reynier brought out his "accumulateur à compression externe," which, in the opinion of some, marks a decided step in advance in the history of the accumulator, and a description of the latest modification of this accumulator appeared in a recent issue of this journal.

## REVIEW.

**The Comprehensive International Wire Table.** Compiled by WILFRED S. BOULT, Assoc.M.Inst.C.E. (Published by the Compiler, 60, Castle-street, Liverpool, 1890.)

This most exhaustive wire table surpasses any previous effort of the kind. The first useful wire table that we remember was that given by Mr. J. T. Sprague in his "Electricity." One of the earliest commercial tables was that of Messrs. Glover and Co., but of late years they have become innumerable. The table before us is by no means a single sheet, but occupies 51 pages of a crown folio volume. The pages are arranged in columns, each column being devoted to one size of wire or cable. The columns contain diameters in inches and millimetres, areas, relations of weight and length, current densities, resistance and length and resistance and weight, and a number of figures relating to the heating of conductors according to Mr. Kennelly. The columns are numbered from 1 up to 452, but these figures have no meaning other than that 452 different sizes of wire are dealt with. Among the areas we find "circular mils" and "circular millimetres," a most confusing, ungeometrical and objectionable idea. A circular inch, according to this system, is the area of a circle whose diameter is one inch. However, the worst that can be said is that two lines of these valuable tables are superfluous.

In giving the sectional area and weight of stranded cables a correction for the lay has been allowed, but it is not at all clear what this correction is. Taking the author's figures, he gives ·023461 as the area of 7/16 B.W.G.; this is 7·0702 times the area of a single strand, or an increase of 1·003 per cent. But the area of 7/16 S.W.G. is given as ·0229, which is 7·12 times, or 1·72 per cent. increase. Again, the area of 19/18 B.W.G. is given as ·036546, or 19·388 times, or an increase of 2·04, while 19/18 S.W.G. is ·0319, or 19·29 times, or 1·52 per cent. increase. These are but trifling discrepancies, and it is very possible that different makers employ different pitches in the lay of their cables. If the increase in length be 2 per cent., it means that the pitch is about 20 times the circumference of the cable.

But the question of the resistance is not so easy to arrive at. If there were no lay, but say seven straight wires, the resistance would, of course, be one-seventh of one wire. If they were practically insulated from each other, the resistance of a given length of cable would be *higher* than that of seven straight strands in the proportion of the increase of weight or length of each. But the author assumes that it is *less*—that is to say, that it is proportional to a cylinder of the given weight and length. This question presented itself to us some time ago. We inquired from more than one maker as to the actual facts experienced, and we learn that it is usual to reckon the resistance from the weight and length, as in the present tables. In the absence of any definite information from actual measurements, we are inclined to think that it would be safer to divide the resistance of a single wire by seven or nineteen, as the case may be, but if any of our readers can throw light upon the question we should be glad to hear from them.

The matter does not at first sight appear to be important, but the resulting difference of 2 per cent. in volts at the end of a cable, one way or the other, is of no little importance.

The only other suggestion we have to make with respect to these excellent tables is, that the gauge number and name should be given in more prominent type, as at present it is somewhat difficult to find any given size.

## ELECTRICAL DISTRIBUTION BY TRANSFORMERS FROM CENTRAL AND ECCENTRIC STATIONS.*

BY DR. J. A. FLEMING, M.A.

*(Continued from page 302.)*

*Station Measuring Instruments.*—In connection with the Thomson-Houston transformer system there are some very ingenious measuring instruments specially devised for alternating currents. There is, for example, an amperemeter and voltmeter (*see* Figs. 26 and 27) which act on the same principle. A light brass arm, swinging on almost frictionless bearings, moves in a vertical plane, and carries at its extremity a small horse shoe, or U-shaped piece of soft iron. A flat circular bobbin of wire, wound on a split brass spool, is fixed with its plane vertical, but centre eccentrically

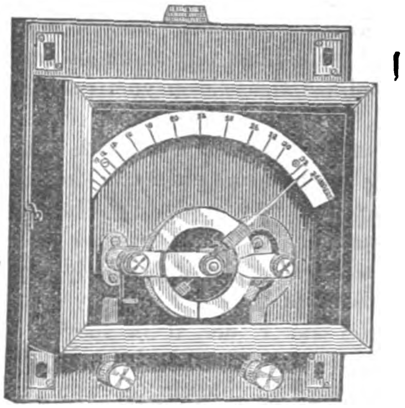

FIG. 26.—Alternating-Current Ammeter.

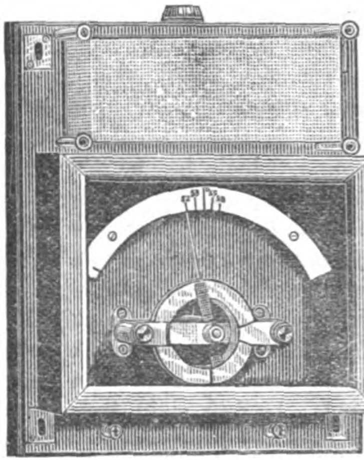

FIG. 27. Alternating-Current Voltmeter.

situated with respect to the pivot of the needle. The U-shaped piece of soft iron embraces the coil, and its motion round the pivot is constrained to be simply a movement nearer to or further from the inside surface of this circular coil. When a current passes through the coil of wire it creates a non-uniform magnetic field in the interior of the coil which is stronger near the inside surface of the coil than it is at points nearer the centre of the coil. The soft iron tends to move from places of weaker to places of stronger field, and in so doing moves the arm to which it is attached round its pivot, and displaces the index arm. This arm carries a counterbalance so fixed that the magnetic force on the iron is opposed by a force due to gravity, and the position which the needle takes up under the influence of these opposing forces is one which is dependent on the strength of the field in the interior of the coil, and therefore of the strength of the current in the coils. The force on the iron due to the current in the

* All rights are reserved.

Digitized by Google

coils is one which depends partly on the strength of the field at the spot where the iron is and partly on the rate of variation of this field from point to point in the circular space. If the spool is wound with coarse wire the instrument may be graduated arbitrarily, and by comparison with a standard as an amperemeter. If the coil is wound with fine wire, and has a German-silver resistance coil in series with it, then the instrument may be graduated as a voltmeter. In the station such a voltmeter is worked off the secondary of a small reducing transformer, which takes current from the mains, and series to measure the primary pressure. These instruments, of course, require to be graduated by comparison with an electro-dynamometer for the particular periodicity for which they are to be used.

*Street Lighting by Incandescent Lamps.*—In addition to the incandescent lighting by single and grouped transformers, the Thomson-Houston Company have elaborated a very good system of street lighting by incandescent lamps which meets the demand for such public lighting over considerable districts in which it would not pay to put down transformers and work the incandescent lamps in parallel off the secondaries. This proves itself in practice to be quick and efficient. In order to keep the current constant for each series line a current indicator is placed on each line in the station, and a switch by means of which one to five relief lamps may be thrown into the circuit. As long as the proper number (viz. 40) of lamps are burning on each series line the current indicator shows a current of 3·5 amperes, but if one lamp breaks or is extinguished the resistance of the circuit falls at once and the current rises. This is shown by the current indicator, and the attendant then switches on one or more relief lamps to restore the current to its proper value. When the broken lamp is replaced by the patrol the current again falls, and the relief lamp in the station is switched off. This series system may be worked by means of a constant potential alternator and primary lines merely for street lighting alone, but it is more frequently used in conjunction with transformer lighting. In this last case the constant potential primary lines are laid about in a district, and from these primaries are taken off not only the distributing conductors to supply the house transformers, but also the series lines for the street incandescents. The arrangement of circuits is then that shown in Fig. 29. Instead of employing the system of

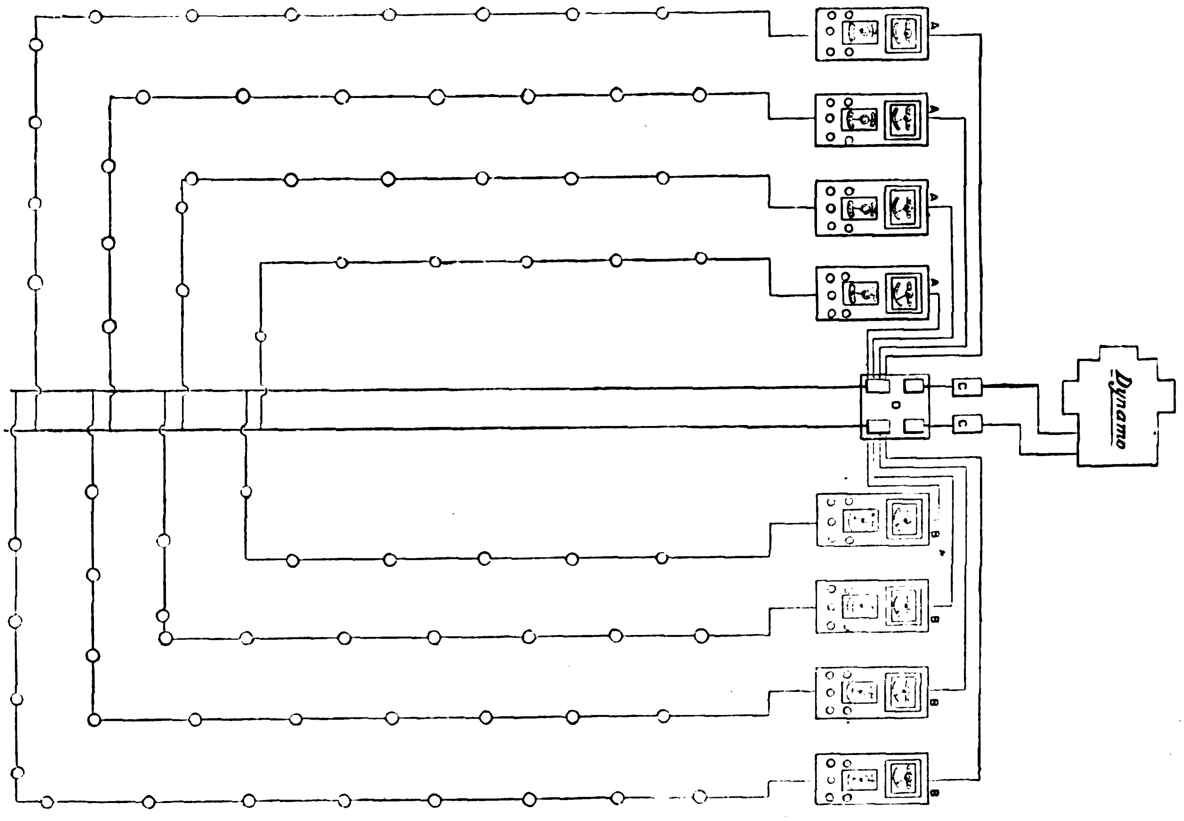

FIG. 28.—Street Lighting by Incandescent Lamps. Diagram No. 1, showing Street Circuits of 40 25 candle-power 25 volt Lamps, or 50 20 candle-power 20 volt Lamps.

system of street lighting consists in running sets of incandescent lamps in series off the primary mains of the transformer circuits. A series circuit starts (see Fig. 28) from a point on one primary of the transformer circuit somewhere in the station, and carries a series of incandescent lamps. This line terminates somewhere or other on the other main primary, and as many of these series lines are run as may be necessary to fill up the district to be lit. The lamps used for this street system require a current of 3·5 amperes, and are of 20, 25, and 40 candle-power. The 25 candle-power lamp is largely used for street lighting. The socket used with the lamp is provided with a spring cut-out, similar to the Thomson Protective Device, the function of which is to keep the circuit closed in the event of the breakage of a lamp. The film is capable of standing the 25 volts required to work the lamp, but in the event of the lamp breaking the full pressure of 1,000 volts is thrown on the film, immediately breaking it through, and thereby short-circuiting that socket. This device relief lamps and current indicator on a bank board, another device is employed sometimes, which consists in using a double socket and double lamps at each spot. One of these lamps only is in the circuit at one time. If its mate breaks, then the second lamp is automatically thrown into the circuit, and keeps a light alive at that place. There is in this case a relief lamp to every lamp, instead of merely five relief lamps in the station. In either case a system of transformer lighting for houses is combined with the street lighting, and the incandescent street lighting is specially applicable in the case of scattered villages and small towns or suburbs, where arc lighting would be impracticable. In connection with this system of street incandescent lighting, light trussed poles of iron are generally used, which carry the overhead series line and also the brackets for the street lamps (*see* Fig. 30). This system of street lighting is being considerably extended. In Malden, Mass., a suburb of Boston, U.S.A., a city of 20,000 inhabitants, street gas lamps have been entirely replaced by about 800 25 candle-

Digitized by Google

power incandescent lamps on this system. The same system is in use at Newton (700 lamps) and Watertown, Mass.; West Point, Va.; Melbourne, Australia; Osaka, Japan; and many other places.

### Thomson-Houston Company's Central Stations. Salem Station.

One of the most complete of the Central Electric Supply stations erected and equipped by the Thomson-Houston Company is that at Salem, Mass., U.S.A. Electric lighting began at Salem in 1881, by the erection of a very small arc-light plant, and has been several times remodelled and extended. Quite recently an exceedingly fine station for an output of 1,700 horse-power has been erected at Salem, and although arc lighting forms the bulk of the work done, yet as there is associated with it alternate-current machinery for incandescent lighting, it may properly be described here. Early in 1888 a site for the new station was secured on Burley Wharf, Peabody-street, close to water, and the erection of the station was begun. The service of lighting was begun in September, 1888. At the beginning of 1890 the current was being supplied for 120 private arc lamps, 180 city arc lamps, 53 incandescent street lamps (series system) of 65 candle-power, 44 of 32 candle-power, and 2,000 of 20 candle-power. The arc-light dynamos are in number 11, of 30 lights each; the incandescent 2, of 400 lights each; 2 of 650 lights each, and 1 of 1,300 lights, and also current is supplied for 50 horse-power in motors. The details of the construction of the Peabody-street plant are as follows:—The station was designed by Mr. Henry C. Patterson, chief engineer of the Thomson-Houston Electric Company. In the construction of this station it was found necessary to drive about one thousand piles of oak and spruce. The piles are held firmly together by an immense bed of concrete made of Portland cement and broken stone two feet thick. On this bed the foundations for engines and shafting were constructed, which foundations are exclusively of granite laid in cement.

In equipping this plant it was thought advisable to install at first one-half of its present capacity. This was done by the erection of two compound condensing engines of 350 horse-power each, and one engine of 160 horse-power. All three engines belt to the same shaft (*see* Figs. 31 and 32), making it possible by the use of clutches to run any one of the engines on the same shaft at one time. In case of accident a defective engine can be shut down, and the load at once taken up by the others. Space is reserved, and foundations are already prepared, for two more engines of 350 horse-power each, and additional shafting. This makes the total output of the plant 1,660 horse-power. The engines are condensed by means of a surface condenser, which returns the condensed water directly back into the boilers, but passing on the way through economisers.

The boiler-house is 90ft. long by 50ft. wide; has space for ten boilers of 125 horse-power each, four of which are already installed with the Jarvis furnace. The boilers are also placed upon granite foundations which rest upon piles, as in the previous case. They are constructed in the most approved manner, from specifications furnished by the engineering department of the Thomson-Houston Electric Company. They are of the ordinary tubular type, 72in. in diameter and 17ft. long, made with extra strong seams and steel tubes, braced in a thorough manner, and having a working pressure of 125lb. to the square inch. The piping of this plant has been carried out with consideration for future output of 1,660 horse-power, and all main steam pipes, as well as exhaust pipes, are large enough for this full duty.

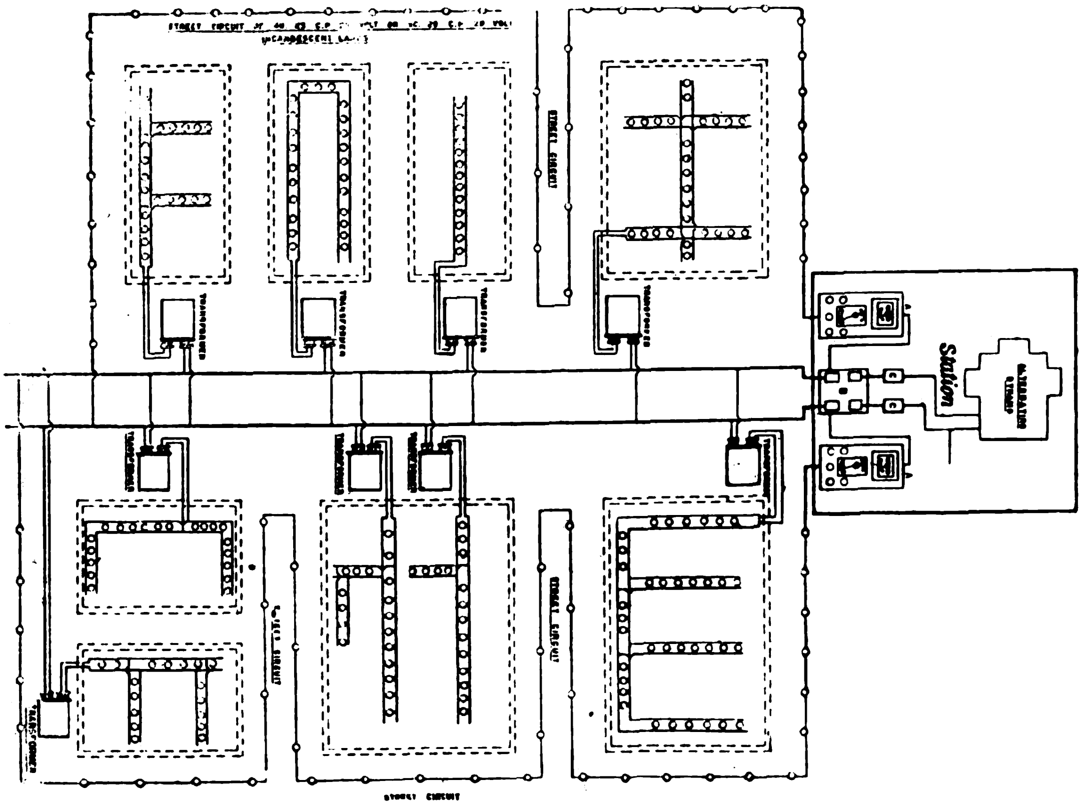

Fig. 29.—Street Lighting by Incandescent Lamps. Diagram No. 2, showing Street Lamp Circuits as arranged in connection with House-to-House Lighting with Transformers.

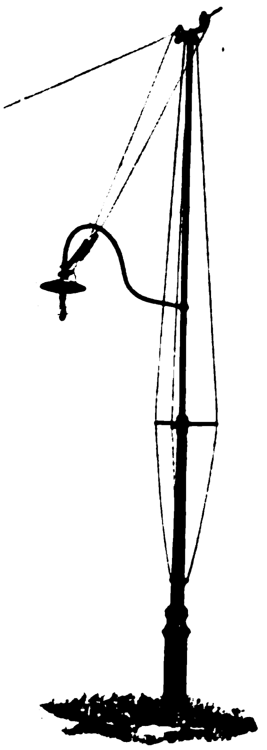

Fig. 30.—Light trussed pole for Incandescent Street Lighting.

The second floor of the main building, which is 115ft. by 66ft., is utilised for machines with a capacity of forty-five Thomson-Houston dynamos, fifteen of which were installed at once. The remainder of the second floor, not used for this purpose, is divided into offices, work-rooms, testing-rooms, toilet-rooms, &c. The coal shed has a capacity for 2,000 tons.

The brick chimney of this plant is 130ft. high, and 13ft. square at the base. The chimney is square in form, with a round core 72in. in diameter at the bottom, and 76in. in diameter at the top. The structure contains 250,000 hard bricks laid in cement, and also 41 perch of granite in the foundations, which rest on 60 oak piles firmly bound together by 3ft. of Portland concrete. This chimney has a capacity of 1,500 horse-power.

Digitized by Google

The entire work of construction, the building, and the placing of the engines, boilers, and machinery was carried out under the direct supervision of Mr. Patterson. In the construction of this plant, it has been Mr. Patterson's endeavour to construct one of the most economical and best running stations possible, and also of an original design. As the Salem Company had increased their plant twice before the construction of this plant, it was their desire to build one of such magnitude as to be entirely sufficient for the future; and as at present they are exerting about 600 horse-power, it would seem that there is ample in reserve for some time to come. Believing that in the construction of an electric light station the best is

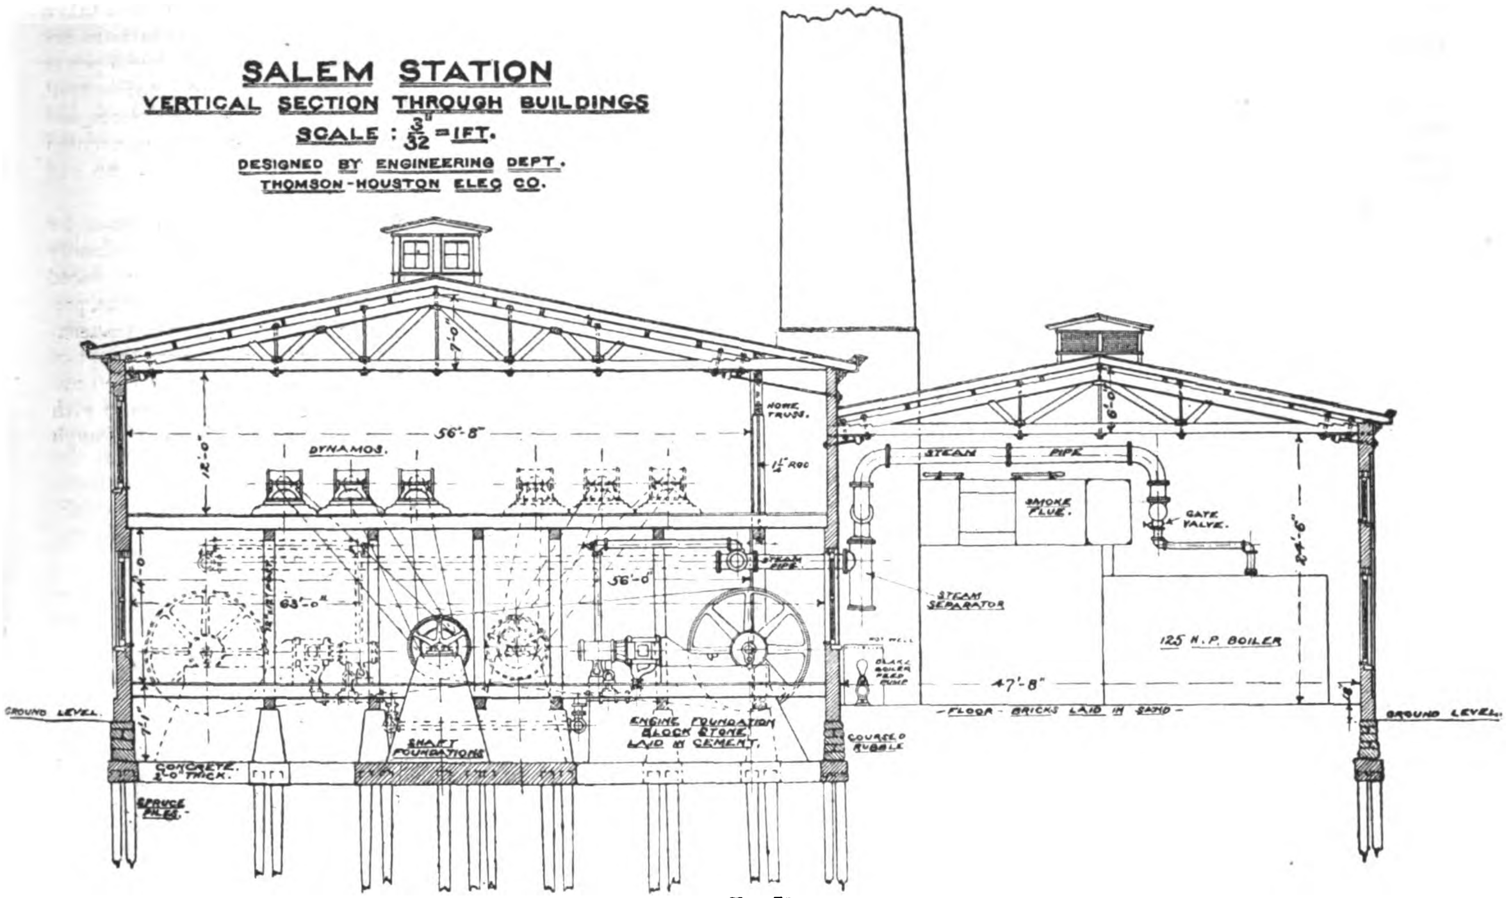

Fig. 31.

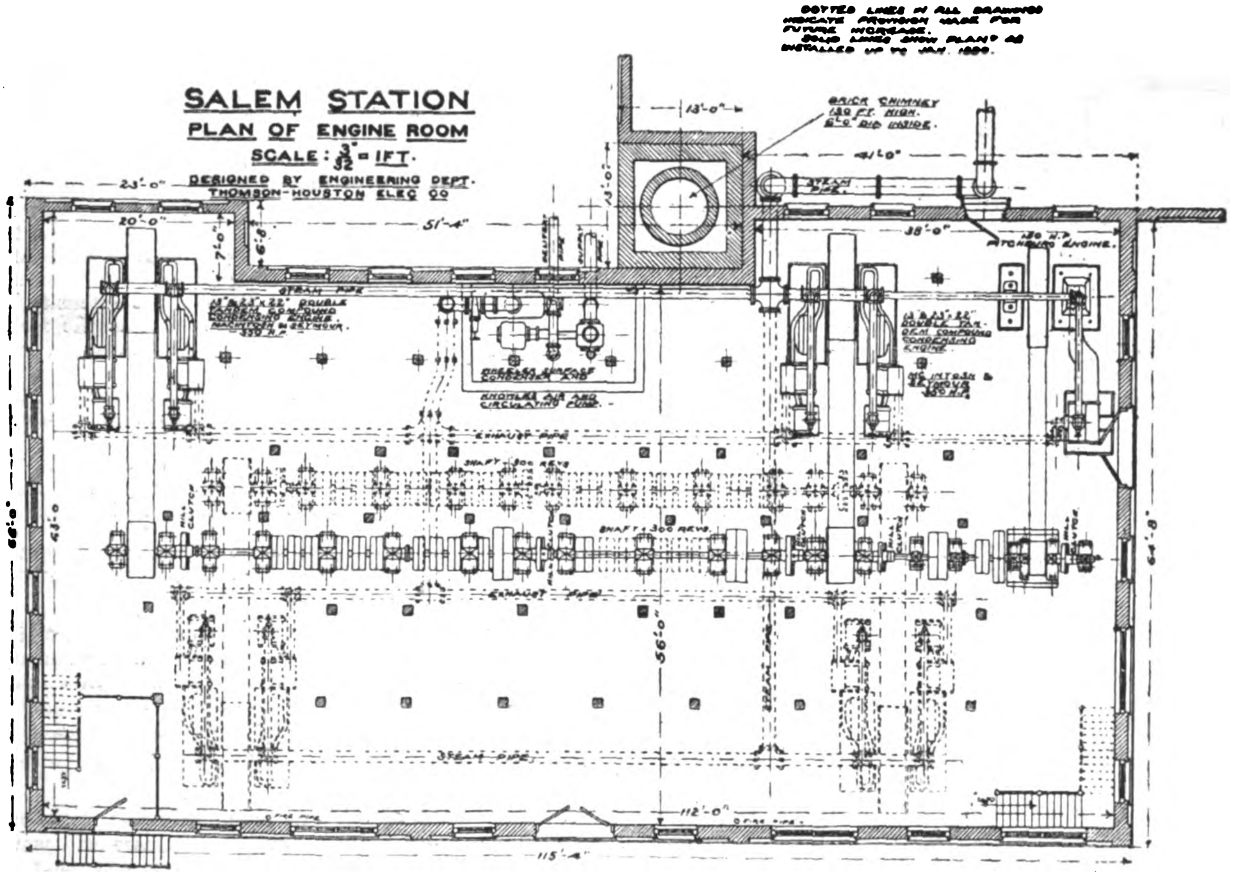

Fig. 32.

Digitized by Google

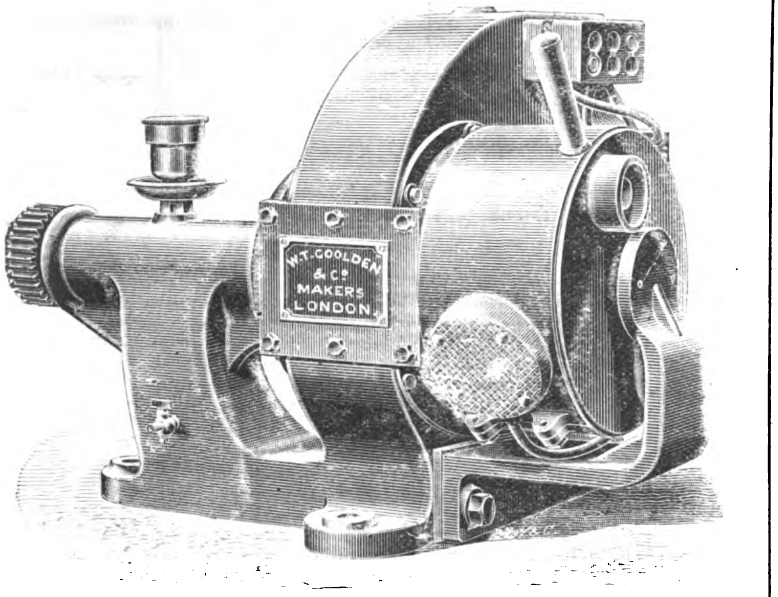
none too good, and that a station should be attractive to the employés, the Salem Company has provided all necessary accomodation for them with the later addition of a library, which is filled with the latest electrical books and periodicals entirely at the disposal of the employés.

In regard to the economy of the steam plant, the change from high pressure to compound condensing, and their present location, has been highly satisfactory, the average coal bills being reduced 50 per cent. since getting the new station into successful operation. This is due to better facilities for getting coal, as also to more economical engines. At a recent preliminary test made with Georgia Creek Cumberland Coal and steam pressure at 110 pounds, the boilers showed an evaporative power of 9·7 pounds of water per pound of combustible. The engines, which were developing a variable load, from 192 to 419 horse-power, showed an economy of 1·8 pounds of coal per horse-power per hour.

*(To be continued.)*

## MOTORS FOR MINING WORK.

Within the last few years—almost it might indeed be said within the last few months—electricity has found a promising field of utility in the application of dynamos and motors to the



various operations of mining. One of the first firms in this country to realise the amount of work which was awaiting the electrical engineer in this direction was Messrs. Goolden and Co., who soon recognised that mining plant had to be designed on very different lines to electrical machinery intended for ordinary above-ground purposes. One of the principal difficulties likely to occur in connection with mining work is the very rough conditions and dirty situations in which the motors have to be used, and a further difficulty in coal mines is the danger that occasionally arises from the presence of explosive gases. For ordinary purposes, even in coal mines, it may be safely assumed that the motor will not be working in an explosive atmosphere, and it is, therefore, sufficient to carry out the arrangement first used some years ago by Messrs. Goolden and Co. of enclosing the whole armature and brushes in air-tight and dirt-tight coverings. These coverings are sufficient to exclude an explosive mixture for many hours, and before such mixture finds its way into the neighbourhood of the armature or brushes the condition of the atmosphere will have been noted by the attendant, and the current cut off.

The annexed illustration shows one form of Goolden mining motor, in which the complete enclosing of the armature is one of several important features. The construction of the armature is unusually strong, since the wires are keyed in every position and insulated from the core and from one another by means of mica. This has enabled these motors to be used for driving hauling machinery, subject to great vibration and shocks, by the use of gearing, thus doing away with belts, chains, and other forms of connection, all of which have proved in practice to be unsuitable for working, at all events, where portability is a *desideratum*, which is the case with the bulk of mining machinery. The enclosure of the armature has been supposed by some to be impossible, on the ground of the want of ventilation; and in the discussion on mining motors, which took place some two years ago at Sheffield, at the meeting of the Mining Institute, several eminent electrical engineers stated that in their opinion it was impossible to work a motor thus enclosed. It is sufficient to state that even at that date Messrs. Goolden were using motors working up to 30 or 40 horse-power with such enclosed armatures. In cases where it is desired to make a machine absolutely safe in an explosive mixture, Messrs. Goolden employ an arrangement in which the volume of gas enclosed in the cover of the brushes in contact with the commutator is as small, or less, than that enclosed in an ordinary safety lamp; and, therefore, should ignition result, the volume of gas compared with the length and cooling surface of the outlet is such that no flame will appear externally. These motors are now being widely adapted for use in electric coal-cutting machinery, electric pumps, electric haulage, and rock-drilling plants.

## THE INTENSITY OF TELEPHONIC EFFECTS.*

BY E. MERCADIER.

The intensity of the action of a telephone depends principally on the thickness and diameter of the diaphragm, the strength of the magnetic field, and the shape of the magnetic field, and of the magnetising coils. I have already investigated the influence of the thickness of the diaphragm, in a contribution to the *Comptes Rendus*, in April, 1889, and shown that for every telephone with a given magnetic field there is a thickness of diaphragm which gives maximum effect.

*Influence of the diameter of the diaphragm.*—Knowing the thickness of the diaphragm for maximum effect, we can vary its diameter. If we do this we discover that there is also a particular diameter, which gives the best effect. This may be attributed to two causes:—(1) The magnetic field only produces a sensible effect on a limited portion of the diaphragm. So that if we increase the diameter we also increase the proportion of the diaphragm, which, from the point of view of induction, is inert, and do not increase the part subjected to induction. (2) By progressively increasing the diameter, we, doubtless, augment its flexibility, and thus assist its movements; but, on the other hand, we also increase its mass, and consequently render its movements more difficult. For the necessarily limited variations in magnetic intensity, it follows from this, and experiment, moreover, confirms the fact, that the diameter, which produces the best effect, must be greater the stronger the field. We thus see how telephones of large diameter, and relatively strong magnetic field, like the Gower, Pollard, and other instruments, do not give better results than instruments with weaker fields and smaller diameters, as the D'Arsonval, Ader, and Aubry telephones. Hence, if we wish to obtain the maximum effect with a given telephone, it is necessary to proportion the thickness and diameter of the diaphragm to the intensity of the magnetic field.

*Influence of intensity of magnetic field.*—This influence is far from being as great as is commonly thought. I carried out a long series of experiments on this point, magnetising the soft iron cores of the magnetising spirals by means of an electro-magnet, instead of fixing them as is usual on the poles of a permanent magnet. In this manner it is easy by varying the strength of the exciting current to produce magnetic fields of widely different intensity. On gradually increasing the strength of the field, a limit is soon attained, after which the telephonic effect is not sensibly increased. This is because the diaphragm rapidly becomes magnetically saturated and an ever-increasing number of lines of force pass across it, as one can see by throwing iron filings on it. Hence an increasing proportion of the magnetic field is useless, so far as the production of telephonic effects is concerned. It must moreover, be remembered that these effects are due to deformation of the lines of force of the field, and that the stronger the magnetic field the more the lines resist deformation by the waves coming from

* From the *Comptes Rendus*, Vol. CXII. No. 2.

Digitized by Google

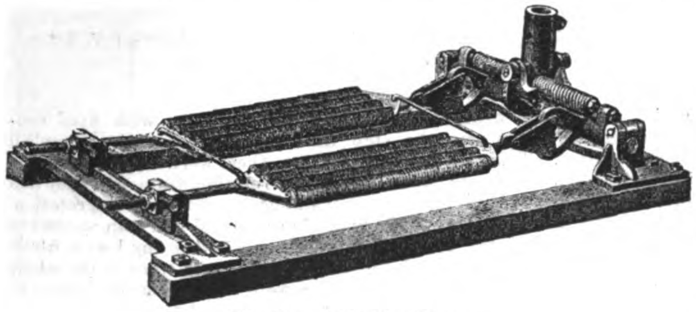
the voice, and the energy of these waves is necessarily limited. This applies equally well to the receiver, in which the energy of the voice waves is replaced by the energy of the electric waves, which the transmitter has produced. We can thus explain the want of success of the many attempts which have been made to increase the intensity of telephonic effects by increasing the strength of the magnetic field, and how, finally, practical men have decided only to use instruments of small dimensions (which are consequently more manageable) with relatively weak magnets.

*Influence of the shape of the magnetic field and of the coils.*—It may be said, without exaggerations, that all possible shapes have been tried, but it is evident that, other things being equal, theoretically the best shape is that in which the lines of force are perpendicular to the direction of the coils. That this is so, indeed, M. D'Arsonval has shown in his telephone, and my own experiments on this subject corroborate this conclusion. Moreover the variation of the shape of the field (the source of telephonic effects) can be facilitated by increasing the mobility of the field, and this can be increased to a certain point by increasing the mobility of the magnet, and of the cores of the coils. This result was recently obtained by Aubry, who fixed the magnet to a vibrating plate, but there is a limit to this which must not be passed, and which experiment determines.

It follows from these well-known effects, which I have pointed out, and from my own investigations, that to obtain the maximum effect from a telephone it is necessary:—(1) To increase the mobility of the lines of force. (2) To pass as many lines of force as possible through the coils in a direction perpendicular to them. (3) To diminish the thickness of the diaphragm, until this is just sufficient to absorb the greatest number of lines of force existing in its vicinity. (4) To increase the ratio of the volume of the diaphragm under induction to the total volume, which necessarily leads to diminution of the diameter up to a certain point.

## ELECTRIC RAILWAY DEVICES.

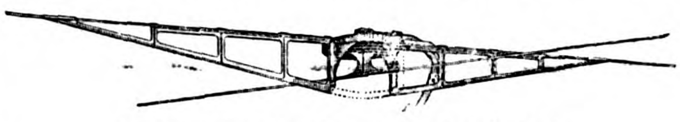
The development of the overhead system of electric traction in the United States has given rise to a great variety of clever devices. In our issue of December 12th we gave an illustrated description of an ingenious trolley base devised by Mr. Charles Lieb, of New York. The trolley base illustrated herewith is one which is, perhaps, not quite so ingenious, but it is one which has been used with success on over 1,000 electrical cars. It is the joint invention of Messrs. Albert and J. M. Anderson, of Boston. The figure



The Boston Trolley Base.

shows the base of the trolley with the pole removed. It will be seen, says the *Electrical World*, that the movement of the trolley pole in a direction parallel to the length of the car, whether forward or backward, brings the eight longitudinal spiral springs into tension. These springs are hung to the rocker arm by a method which provides in a very ingenious manner for maintaining a constant tension in all positions of the trolley arm. The forward and backward motion of the trolley arm brings into action the one or the other of two independent centres between the springs and the rocker arm, and this arrangement is such that a very slight motion in the trolley will put the springs under tension. The movement of the trolley pole at right angles to the length of the car is provided for by an axis of suspension at right angles to the main axis and by two spiral springs placed as shown. All these springs have suitable adjustments for regulating the tension.

In a recent issue the *Electrical Engineer* of New York describes the Bagnall Trolley Wire Crossing Device. In the erection of overhead trolley wires, where the tracks of one company cross the tracks of another, the company first to erect their trolley line will obviously have the right to the most favourable position, that is, the under position. The company last on the ground are required to take the upper position. Their cars are, therefore, left without current while passing the crossing. The current must be shut off from the motor before reaching the crossing so as to avoid arcing at the crossing gap. The Bagnall trolley wire crossing, manufactured by the Emerson Electrical Manufacturing Company, of St. Louis, is designed to avoid this difficulty and maintain continuity of the current to the trolley arm while passing such a crossing. The accompanying illustration shows a perspective view of the device. To the upper trolley wire is attached a bridge-piece of light lattice casting, at the centre of which is a gap through which the under trolley wire passes. It is attached to, but insulated from, the bridge by means of a disc of insulating material placed in an inverted cup at the centre of the bridge. A curved lever hinged to the upper side of the insulator cup rests by the action of gravity in the position shown. The passage of a trolley wheel along the wire from right to left will carry the lever along with it, and thus bridge over the gap as shown by the dotted lines and maintain a continuous connection between the upper trolley wire and



Bagnall Trolley Wire Crossing for Electric Roads.

the trolley wheel. After the trolley wheel has passed over the gap, the lever is released and falls by gravity into its former position of rest. The hinge and guides of the lever are protected by a hood—not shown—as a protection against ice. In fixing this crossing in position it is not necessary to cut either of the trolley wires. It is attached directly to the upper trolley wire by means of clips and solder, and the under trolley wire is attached in the same way to its insulator web. In case of slackening or changing in position of the trolley wires, the clips can be unsoldered, and the bridge moved along in the direction necessary to secure the readjustment and then soldered again.

## LEGAL INTELLIGENCE.

### British Tanning Company v. Groth.

THURSDAY, JANUARY 15TH (*continued*).

Mr. MOULTON, Q.C., in addressing the Court in support of the defendant's case, said that in this action he had one great advantage, and that was that the nature of the case was such that the evidence that had been given—and which he might say, and he thought his lordship would agree with him, had been given very fairly by the witnesses of the plaintiffs. But they had certainly given him evidence on which he should be prepared to submit that the plaintiffs' case had broken down. He did not think his learned friends had fully appreciated the case that had been made on either of the two main points—that of anticipation by prior publication and the point of the convention; in fact, he thought he might say that his lordship had shown he was considerably ahead of them in appreciating what the defendant's case was. It was a case, in his opinion, that depended on some very fundamental matters in patent law, principles that would scarcely be denied by his learned friends, and the application of those by the Court in the way laid down again and again by many judges and by many Courts. To the particular specification in this question he should submit that was sufficient to decide this case on the evidence that had been put before his lordship for the plaintiffs. It had been said again and again there were three duties on a patentee; he must first make an invention; secondly, he must describe it; and he must, thirdly, delimit his invention. Our law was not like that of other countries, because a patentee described or delimited at his own peril. If the patentee made his narrow he had the additional security of showing that it had not been anticipated; if he claimed widely his patent was much more valuable if it could be sustained, but if in any portion he was anticipated his patent was bad. As his lordship was well aware that was left to the patentee to do at his peril. What were the principles of interpretation applied to a patent? The Courts more and more every day were getting fairer, not by having what in many cases in olden time was an exceedingly benevolent neutrality, but in trying to hold the scales evenly between the public and the patentee. He could cite a dozen cases in which the Courts had said they were not to strain a patent, either in favour of a patentee or of the public. Of old there was a notion there were monopolies; then came the natural reaction. There was what was called the beneficent interpretation in favour of the patentee, but now the Courts saw there were neither of those things right nor fair; what they must do was, they must try and fairly construe as between the patentee and the public, having a bias for neither. What was the material construction? A patent in its novelty, in its description, and in its delimitation had always to be judged by the knowledge of the time, and to be taken as being addressed to persons who possessed substantially that knowledge. He thought that would be taken and would be accepted by the Courts at the present time as the real material on which the Court had to do the whole of its construction, and on what the inference had to turn.

The ambit of the patent was to be determined by the construction of the specification in view of the knowledge at the time as possessed by

Digitized by Google

those people to whom the patent was taken to be addressed; that was, the people who were in the trade or profession who had to deal with the particular subject matter, and the Courts had again and again said that the Court was to instruct itself up to the point, to take the evidence of experts, and it might take evidence as to the state of public knowledge so far as possible, to put the Court in the position of one of the persons to whom the patent was addressed. Once having done that, the whole responsibility was upon the Court. They judged of the validity or invalidity of a patent by whether or not it was valid or invalid at the moment when it was applied for, and they judged of the ambit of a patent in the same way. The ambit of a patent could neither be increased nor decreased, except by way of alteration by disclaimer, which was not the question here. Let him apply those principles to this patent; first of all, let him put himself in the position of a person who was a tanner at the time the patent was first taken out. In the first place, they had it that tanning was well-known for more years than one could count—perhaps even as far back as the time when Noah took to business again—to be a process in which skins were turned into the more durable article, leather, by the absorption of the tan liquor through the orifices of the skin; and it was known perfectly well that these skins took away the tanning substance from the portions of the fluid nearest the skins, and therefore those, excepting by the slow process of diffusion, were impoverished, remained impoverished, and the action got less and less active as that impoverishment went on. What did practical people do? It was fully realised why they took out the skins and moved them about; it was to keep the liquid well mixed up and all equally charged. The result of that was that people said they would substitute a mechanical disturbance for hand labour, and plant after plant was laid down for this purpose. In the plaintiffs' process they had a description given of a huge barrel with rows of pegs inside. The barrel was about one-third filled when the hides were thrown into it with the tanning liquor and some other ingredients. Then when it was turned round the hides got heaped up on one side so that they were always working against that weight. The hides rolled over against each other and splashed in the water. The consequence was that so much power was used in moving these and wasted in the friction between the hides that they actually raised the water 10 or 20 degrees in temperature. This rise of temperature came from the churning of the hides, and was confined within the barrel. His lordship would see that a vast amount of motive power must be used in the turning and wasted, but it had been said by Mr. Blackmore that the increased temperature in consequence was one of the most important parts of the plaintiffs' invention. Because it was absent in the defendant's process Mr. Blackmore said they could not tan the hides under 35 days.

But let them see if there was not another factor. The hides were rolled over and over, and Mr. Blackmore said that was one of the things that would affect the tanning. Let him go on. There was one thing that everyone admitted, viz., that the bending of these hides over one another produced a special suppleness, and that if they did not want it they had to use it with only a small amount of hides; whatever charge they used they must produce this suppleness, this rolling and kneading action. The only effect of the rotatory drum, added to all the previous methods and subsequent methods of mechanical motion in tanning, was just to freshen the liquor. The liquid moved in a body, and, if he might say so, it was something like the way in which the articles were dashed in bleaching; they were thrown over and over, and they had a violent action for the purpose of effectively doing these things. He should show presently that it was admitted by the patentee, and relied on by the patentee, that this rotatory drum was a specially effective tanning agent, with advantages of its own as contrasted with other methods used in tanning. He would not go into the other instances of motion which they proved existed, but he stopped here to explain the state of knowledge at the date of the plaintiffs' patent. One had to put one's self in the position of persons knowing and familiar with those things, both in justice to the patentee and in justice to the public.

Now he went to the patent, and here he was in a most peculiar position, a position, he admitted, of advantage to him. He had got two patents, and it sufficed for his purpose to show that he was outside either for this reason. His learned friend said with regard to the patent in the convention, that if a person at that date came into England within seven months of taking out a patent in France, and took out a patent for the same invention in England, his patent was valid in spite of prior publication in England. Let him point out what that led to. If the English patent was wider than the French one, then he had not patented the same invention; he could not patent A in France and then come to England and patent A plus B, and say he had a right to antedate his patent. The Patent Office was now so strict that he believed they insisted that the specifications should be in the same terms. But he said, that if he could show the invention patented in France was outside the French patent, his learned friend was in this dilemma, either it was the same ambit, and was right, or it was wider, and he could not take advantage of the convention. What he was going to do was to ask his lordship to take the French patent with him, and to put himself in the position of persons of those days who knew the principles of tanning, and that movement had been obtained in all sorts of ways, but that a special way had not only obtained movement, but had special advantages; he asked his lordship to do as the Court ought to do, to construe fairly as soon as he had the knowledge of the time. He would now begin—"The idea of applying electricity to the tanning of skins in pits has already been entertained, and the various inventors who have tried that process have all ascertained the favourable intervention of electricity from the point of view of rapidity of tanning." That said frankly enough it was well known by many inventors that electricity would accelerate tanning, and it was frankly admitted by Mr. Swinburne that meant the absorption of the tanning from the liquid. "On the other hand, the utilisation of rotatory drums for the tanning of skins produce economical advantages which are too well known for it to be necessary to repeat it here." Now, what did the patentee say? He said he appealed to French tanners; they knew how well the rotatory drum had gone; it kept it all in, it got warm, it splashed, and it made the things supple. Those economical advantages, as they saw, were attributed by the patentee to the rotatory drums, and that the rotatory drums had special advantages possessed by no others; that it was so well known there was no need to repeat it. "We have conceived the idea of applying electricity to this latter mode of tanning—that is to say, tanning by rotatory drums, by placing the skins in contact with the tanning juices in the interior of revolving drums." Was it possible for any patentees to have said more, to let an honest member of the public reading that know what the invention was, and coming to the delimitation of the invention, would he not say to himself, the patentees meant to combine the advantages of the rotating drums and electricity by applying electricity to the hides while they were in these revolving drums? "By this combined action of electricity and rotation in the apparatus an extremely rapid tanning is obtained." He treated as co-ordinate the electricity and the revolving drum; he used the same language to people knowing the object of one and the other, and it would be just as fair to say that something else besides electricity was included as something else besides revolving drums. He (Mr. Moulton) called that an honest specification, and he thought his lordship would see it was thoroughly honest from beginning to end. There was no attempt to hedge, and there could be no doubt that a person who used these words with an intention of going beyond them would have been deliberately deceiving the public. The patentee said that in order to carry out this process of rapid tanning by the double action of electricity and rotation, they had had to adopt the construction of the rotatory drum. By adopting that scheme meant the obtaining the passage of the electric current through the drum. What did the inventors consider to be the invention? They had made a rotatory drum, and to adapt electricity to it they fixed

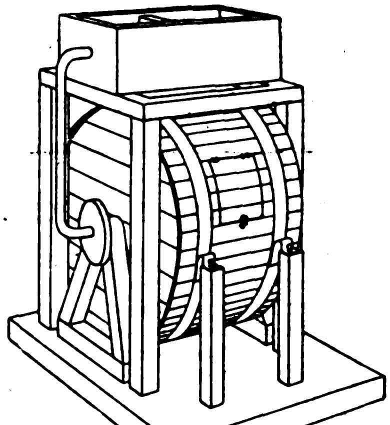


FIG. 1.—Worms and Balé (plaintiff) Machine. Model "S.P.T. 3."
(See *The Electrician*, Vol. XXV., p. 37.)

on the rim of the drum two parallel rims of copper with fixed conductors inside. That was the step that enabled them to accomplish their invention. Taking a rubbing contact they were always applying the electricity which would pass through the rotating drum, and they had solved the problem of combining the advantages of electricity and rotation. The inventor had stated what his invention was, and if a man wanted to limit himself to that, he (Mr. Moulton) doubted whether any better words could have been used; he could not see an ambiguous word in the whole article. It was perfectly well known there were other forms of motion to which electricity could be applied, and that the patent could not claim all of them; but this was an attempt to ride in a wider meaning than the patentee meant, or than the public understood, and that was what he (Mr. Moulton) protested against. The meaning of the patent was settled the moment the patent was taken out; it was the meaning which a person well instructed in what was the knowledge of the time would fairly—trying neither to widen nor to narrow—understand the patent to be, and who, knowing the state of knowledge at the time, must come to the conclusion these people claimed what they had stated and described, viz., a device which, by using a rotating drum with circular electrodes and rubbers, enabled them to get the well-known advantages of the rotating drum and electricity; that they never patented anything else; and that if that was established the Court would not widen the specification. The Court would not, because it thought the patentee might have claimed more, alter his claim and make it more than he felt it to be. When they came to read the French specification, one could not come to any other conclusion than there had been no infringement, for it was not suggested that what the defendant did was either to use the rotating drum or to get the well-known economical advantages of the rotating drum. He would point out that it was admitted that the defendant did not by his process get the well-known advantages of the rotating drum, and Mr. Blackmore said it would take 35 days to complete the operation of tanning, and that, apart from electricity, the defendant's method would fail. He thought Mr. Blackmore rather overdid it. The defendant did not think so poorly of his method, and he (Mr. Moulton) did not think the plaintiffs thought so poorly of it, or they would not have given them so many eminent people in the witness-box or have brought the action; but that was a detail. What the defendant said was that it was not the same

Digitized by Google

appliance as the rotating drum, and since the plaintiffs had claimed only the advantages of the rotating drum, that therefore they could not now turn round and say that the defendant, who had not used that, had infringed their patent.

At this stage the further hearing was adjourned until Friday morning.

FRIDAY, JANUARY 16TH.

The hearing of this action was resumed before Mr. Justice Romer on Friday, when

Mr. MOULTON, Q.C., continued his remarks to his lordship on behalf of the defendant. He said that when the Court rose the previous night he was going through the French patent in order to show the patentees there only claimed the application of electricity to one particular form of tanning plant; it was a combination of a drum and electrical action, that the patentees treated as two co-ordinate factors, the rotating drum and electricity. Whatever might be the result of the matter on the legal point, he felt sure that the patentees, Messrs. Worms and Balé, never intended to do more than claim a combination of a rotating drum and electricity, and if they obtained anything more it would be because the law forced it on them. He was now going to examine into the proposition, aye or no, did English law give a patent any wider meaning than a man meant it to have, provided he used words which fully carried out his meaning? He was not going to say a man might not draw a patent and give it a wider meaning than he meant, but taking the words used and the meaning they would bear to the instructed people at the time, which was the meaning they must suppose he had, was there any doctrine in English law that gave a patent a wider meaning than that? He submitted there was none; there was no authority and no reason for it. That was the point of the case The advisers

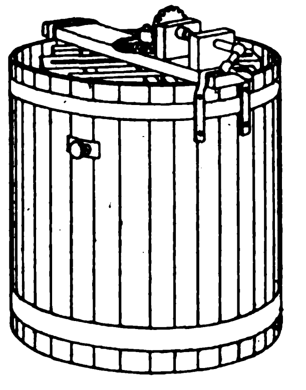

FIG. 2—Groth's (defendant Rotary Machine. Model "S.P.T. 1."

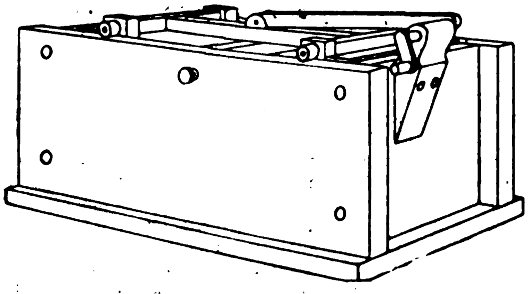

FIG. 3.—Groth's Reciprocating Machine. Mode "S.P.T. 3."

of the patentee said he might have made a broader claim, as they did not find that anybody claimed electricity with mechanical motion. If the patentee had claimed that it would have been safe, but he would show they asked them to read this claim, or the broadest claim the patentee could have made in the light of subsequent knowledge. That, he said was not permitted in English law. They had a right to stake out their ground, but they did it at their own peril; if it was too wide a plot it was bad until it was altered, and if too narrow they had that and nothing else. The late Master of the Rolls said, "The claim shows all that he keeps for himself, and everything without that claim is not his." Here he said these persons had a knowledge of many ways of applying motion; when they came to stake out their plot they said they claimed the rotating drum and electricity. Whether it would have been possible to make a wider claim, they did not do so, and now he said his lordship could not read that to be a claim generally for combining motion, which at that time had been done in many other ways with the rotating drum, and electricity. If he could convince his lordship of that, the whole of the evidence of the plaintiffs went, for every one of the experts was obliged to admit that it was because of the two factors, motion and electricity, that they considered the defendants an infringement of the plaintiffs' patent; in other words, if those were sufficient to constitute an infringement, it must be that the patent generally was for a combination of those two things. Suppose a man was to use instead of a rotating drum a sphere rotating upon a horizontal axis, the answer would be it behaved as a drum, the motion of the hides, the plashing in the water, the giving off of gases, everything was the same, and there a sphere and a drum were identically the same things; they had only coloured their invention.

Mr. JUSTICE ROMER: It appeared to me earlier in the case, and still does appear to me, that the real question here I have to try is whether or not the form of instrument you may use, apart from electricity, comes substantially within the meaning of the tanning machine known as the rotating drum.

Mr. MOULTON said that was exactly what he was about to argue, and the instance of the sphere he meant to be an exact instance of that, aye or no, did it come substantially within the meaning of the rotating drum? That was what he was leading up to when he said he would meet the question of a mechanical equivalent. That which was protected was that which was specified, and that which was held to be an infringement must be an infringement of that which was specified. Defendant's process was nothing like a rotating drum, and the accident that it was round was due to the fact that it was convenient to try it in a tub, a brewer's mash tub, but it practically was a pit; they had a cage or framework, and it need not revolve, but move forwards and backwards. All these were familiar characteristics to persons acquainted with tanning, but none of them would call the defendant's moving frame a rotating drum. The issue to be decided was whether a person at that date would have taken defendant's models to be, in the language of tanners, a rotating drum, and to be referred to by Worms and Balé in that way.

Mr. JUSTICE ROMER: You are going to call evidence? On the plaintiffs' side there is not much evidence directed to the present state of the tanning trade.

Mr. MOULTON said he would call a witness who would prove that. There had been a question about mechanical equivalent. The first thing necessary for a thing to be a mechanical equivalent was that it should be an equivalent, so that the world could say it was a mechanical equivalent. It could not be said that defendant's model was the mechanical equivalent of the plaintiffs', when the action upon the hides was so different.

Mr. JUSTICE ROMER: It is not a question whether it is a mechanical equivalent for the purpose of motion at large, but whether it is so far the class of motion covered by the rotating drum.

The ATTORNEY-GENERAL said the better expression would be a known alternative.

Mr. MOULTON: A known alternative for producing the same thing; it must produce the *same* thing, or it could not be an equivalent. His learned friend said that the drum was necessarily a mechanical equivalent for a cage revolving in a vat. If his learned friend went to a fair, and bought a merry-go-round, he might succeed; but if he put the people in a revolving drum, and told them they would be equally successful with that, he thought he might have some trouble (laughter). So far as tanning was concerned, the defendant's process was totally different from the treatment the hides were subjected to in a drum, and it was no use saying it was a known equivalent. There might be cases in which the drum might produce the same mechanical action, the hides might be stretched in such a way that the action would be the same as in defendant's model, but before it could be a mechanical equivalent they must show it produced the same result. The moment they considered it in that point of view the possibility of equivalents went at once, and that was why he asked if there would be a good patent for the plaintiffs' model? Of course there would. It was a very daring thing to use the hides in the way they were used in the rotating drum, because it spoiled some leathers whilst it improved others, but they were no more equivalents than two broadly different modes of action, therefore he said they were not mechanical equivalents. Bodies stretched upon a frame, and then turned round, were not known substitutes, because they would not do one thing for the other. In the same way sweetmeats rolling over one another and rolling against each other.

The ATTORNEY-GENERAL: Really we know nothing about sweetmeats. There is deal of this scientific evidence that does not come from the witnesses.

Mr. MOULTON said it was used as an argument. His argument was that the plaintiffs must prove that the defendant's process was equivalent in its action to theirs, and in this first stage the plaintiffs broke down entirely.

Mr. JUSTICE ROMER: Mr. Attorney-General, for the explanation of the Court, may I ask whether you contend that under Section 103, when there has once been a Convention with any foreign country, that a person who applies for protection rather than a patent, that person must only obtain the limited term, or has he his choice open?

The ATTORNEY-GENERAL said that since the new rules he could not deny that a person had his choice, but before the new rules were framed that was not so. He should put it as argument before his lordship that the patent must be dated back, and if not, the result would be that the term of the patent would be shortened at the other end.

Mr. Justice ROMER: Between 1883 and 1885?

The ATTORNEY-GENERAL said the new rules were dated May 15, 1888.

Mr. MOULTON said they were merely rules made under the Act. He must not be taken as admitting there was no way of persons informing the Patent Office of any point they wanted to raise. The new rules were not a fresh enactment.

Mr. JUSTICE ROMER: That does not relieve the difficulty in the Attorney-General's way; he would have to argue the effect of the rules was to alter the effect of the statute in a very serious point; that the effect of the statute was to deprive the inhabitants of such foreign country of their choice which was restored to them in the rules.

Mr. ALFRED WILSON, a practical tanner, was the first witness called, and he stated that he had been engaged in the tanning business for a period of over 30 years. Prior to the year 1887 there had been various means of mechanically moving hides whilst in the process of tanning. He had worked with some of them himself; he had worked with the form of dipping the hides up and down on a frame, and with the American rocker.

Digitized by Google

The ATTORNEY-GENERAL said he understood this evidence was being taken not for the purpose of narrowing his specification, but to improve the knowledge of the Court.

Mr. JUSTICE ROMER: Certainly, that is so.

Examination continued: There were several methods of motion. He had seen both defendants' modes. The round one (Fig. 2.) was novel as far as the mechanical arrangement was concerned, but the vat was an ordinary one used in many Continental States. The mechanical arrangement caused the hide to rotate and the liquor also. The mechanical arrangement would work equally well in any other shape. An instrument known as a rotating drum, similar to that of the plaintiffs' (Fig. 2.), was known in the tanning trade.

In cross-examination by the ATTORNEY-GENERAL, he had never seen a cage on a vertical shaft in which skins were suspended. He had seen hides suspended on a drum, the shaft horizontal and turned round in tanning liquor. The axes were immersed in the liquor, which went over the whole framework. That formed the patent.

Mr. JUSTICE ROMER: Was that a distinct patent from the other?

The ATTORNEY-GENERAL said that whether a patent or not made no difference for his purpose, as they were not set up as anticipations.

Cross-examination continued: Provided there was clearness for the skins to fall over, it made no difference whether it was a pit or a drum.

Re-examined: In the case of tanning on the outside of rotating drums, the skins were attached to movable sticks placed on the drum and practically forming the drum. They were fastened only at one end, and rubbed and fell against one another in the operation.

Dr. RIDEAL, Lecturer in Chemistry at St. George's Hospital, said he had given attention to the subject of tanning. He knew the various forms of plant used in tanning before the date of 1887. He had heard the various forms given for motion in use before 1887, and he agreed with those descriptions. There were also several other forms to those described of the use of motion so as to keep the liquid fully charged with the tanning. He knew of the process of tanning in a revolving drum, a process that was always accompanied with a great rise of temperature and pressure. The absence of air in an enclosed drum also affected the tanning process. The hides by being beaten about lost a considerable quantity of material, such as gelatine and albumen, which was beaten out of the hides by the operation of the revolving drum. This made the hides more supple when finished. Such a drum was used for special kind of work. He had seen both defendant's models, and believed these two forms were about equally efficient when used under the same conditions. They were used with an open top, except that a board was placed on the top to prevent the liquor splashing out. The operation to which the hides were subjected was not the same as the operation in the revolving drum, and he did not agree with some of the witnesses yesterday in that respect. In both of defendant's forms the hides were suspended, whilst in the revolving drum they were loose. In the two forms of the defendant's apparatus the hides were placed parallel to the electrodes, whereas in the revolving drum the hides would be at right angles to the plane of the electrodes. The defendant's two forms were similar in that respect, and, therefore, differed from the revolving drum. There was no rise of temperature or kneading of the hides in defendant's process, whilst these actions took place in the revolving drum. These matters affected the result of the tanning, and he should think the defendant's process was best for sole leather, the plaintiffs' being better for kips and bazils. Prior to 1887 a form of tanning was known to tanners as tanning with the rotating drum. He should certainly not call either of defendant's models a rotating drum.

Cross-examined by the ATTORNEY-GENERAL: He gave this evidence as an expert witness, and not as a practical tanner, though he had tanned skins. The defendant's process required, when worked alternately day and night, about a month to repeat the tanning process. He had never heard that if worked consecutively the process required only 80 or 90 hours. He had seen motion and electricity applied for a period of eight or ten hours. He had never tried to tan consecutively by the process for four or five days. From the rate at which tanning took place in the eight or ten hours, he should say it would not tan in four or five days; he should be very much surprised if it did. Leaving electricity on one side, he considered the principal object of the rotatory drum was to produce the suppleness that was important in kips and bazils and all soft leather. Undoubtedly one of the objects in keeping hides immersed and the tanning liquor in motion, was to bring a stronger liquor to bear on the hides. The principal object in the defendant's apparatus was to cause a uniform action of the liquor and electricity on the hides. It was only an advantage to remove the gelatine and albumen in the case of soft leathers. Speaking generally, he should say that no gelatine or albumen was taken out by the defendant's process, and he should not use defendant's apparatus to produce soft leathers. He was not chemist to the syndicate, and had nothing to do with it. Mr. Groth asked him to examine his work, and he did so. He had seen defendant's original specification, and he thought to describe the apparatus as a revolving drum was a peculiar word to use.

In re-examination Dr. RIDEAL said that upon a vertical axis the hides could not tumble over one another as in a revolving drum. In a revolving drum the hides lost in weight, but gained in softness. The revolution of the cage in defendant's apparatus moved the fluid.

Mr. A. TROTTER said he had given great attention to electricity and mechanism. He had been to the Grange, Bermondsey, and seen the defendant's process in work frequently. He had, in co-operation with the last witness, made experiments in the tanning produced there. With regard to the results produced by the two machines used by the defendant, they found them to be almost identical as measured by the absorption of tannin. As to the amount of power required to work them he should estimate it was about one-eighth of the power required to work the plaintiffs' apparatus. He should think that defendant's reciprocating machine would require one horse-power to work and the round model considerably less, whilst the plaintiffs' would take at least seven horse-power. Nothing could be more different than the effect upon hides in a revolving drum and these placed in a drum with a vertical axes. A vastly smaller effect would be the result if the cage were held fast, and the vat rotated, compared with a stationary vat and a rotating cage. The only motion that could be produced would be due to the friction on the sides of the vat. If the vat were turned round and the cage kept fixed, the motion would obviously be where there were no hides, that is, nearest the walls of the vat. It appeared to him that the effect of the electricity in the plaintiffs' machine must be somewhat localised; and if he might take Prof. Sylvanus Thompson's evidence, in which he said the current was more dense under the shaft, it would be more localised than he had previously estimated. In defendant's round model it was almost uniform, and the hides had every opportunity of presenting themselves to its action, and in the reciprocating machine it was as uniform as any current could possibly be.

Cross-examined by the ATTORNEY-GENERAL: He should hesitate very much to accept the statement that it only took 1½ horse-power to work the plaintiffs' machine. The electrical action upon the hides was better in defendant's process than the plaintiffs', because it was more uniformly produced. Beyond that he did not suggest any difference.

This closed the defendant's evidence, and

Mr. MOULTON said, that having addressed his lordship so recently and so fully, he did not intend to say more than a few words. The only new point was with regard to the interpretation of the specification. The learned Attorney-General had put in a specification of the defendant's, but the complete specification completely corrected the use of the word "drum." What his lordship had to decide was the meaning of a public document, and the substance of the case, apart from the construction, was the question, aye or no, was what the defendant did a case of tanning in a rotatory drum as understood by tanners. Not one of the witnesses said that what the defendant was doing would be called using a rotating drum. He submitted that the plaintiffs had chosen for the patent a narrow ambit, and that the defendant had succeeded, and if he succeeded on that, he ought to succeed also on the question of the invalidity and non-infringement.

Mr. JUSTICE ROMER asked Mr. Farwell, who was about to reply on behalf of the plaintiffs, whether, after the passing of the Patent Act, the plaintiffs could not have applied for a patent for the full period, and not have applied under Section 103.

Mr. FARWELL submitted there was at the time no distinction in the form of the application. With regard to the point of infringement, his lordship had heard the various witnesses, and it came back to whether it was or was not a colourable imitation. All they said was that the hides might more or less be tumbled over. According to the plaintiffs' system, in their machine it appeared from the evidence, if they desired to tan, not rendering the leather supple, it was simple to do so by adding to the strength, diminishing the number of hides in the machine, and working the machine slowly, so that they could tan hides for all purposes in the machine invented by the plaintiffs. Did it make any real difference that the defendant said by his process they could only tan in one way? It really came back to this. They found the two processes; they found motion, leaving out the question whether it was rotatory or not; the only distinction between the two processes was that the skins were doubled up more in one than the other; the gist of the matter was electricity applied to motion. They had in both the same tanning liquid and acceleration, and having the same rotatory motion, so that everything was common except that the defendant's rotation was done by means of rotation inside the barrel instead of, as in the plaintiffs', the barrel rotating with the hides inside. The only distinction the defendant could point to was that in plaintiffs' it was more adapted to produce soft leather, and in producing sole leather they had to vary the mode of operation; that was really the only distinction. Because the defendant took a variation of the plaintiffs' invention did not make it less an infringement, nor was it less an infringement because it had not the advantages that plaintiffs possessed. His lordship had the case fully before him, and he would leave it in his hands.

Mr. JUSTICE ROMER then delivered judgment. He said: The two points in this case I have to consider are—first, invalidity of the patent owing to prior publication; secondly, the infringement. I will deal with the question of validity or invalidity first. The point is a very short one. The patentees in this case, before they obtained their patent in England, had patented the invention in France, that an abridgment of the description of the invention as contained in the French patent was published in this country through an American translation before the date of the English patent. It is admitted by the plaintiffs that that would be such a publication as would vitiate the patent in England, except, as they say, for the special provisions of Section 103 of the Patent and Designs Act of 1883 and the amended Act. Now there are, no doubt, some difficulties in the wording of that Act, but it appears to me that, notwithstanding the passing of that Act, from the time of it and throughout to the present, any person applying here for an English patent who had previously obtained a patent in a country with which a convention had been made according to the Act had a double right, he could apply for the restricted patent or restricted rights given him by Section 103; or, if he was under the impression that the foreign patent had not been published here, he still had the right to obtain the ordinary patent for the full period. The two rights would be distinguished when you looked at the width of the patent he obtained, by seeing the date of it, because if he had obtained the limited rights given him by Section 103 his patent would have to bear the same date as, according to the Act of 1883, the protection obtained. The date of the patent, in fact, would show the right he had obtained. In this case it is clear that the patentees did not limit the claim or obtain the limited right. Their patent dates from the date of the application in this country. It does not bear the date it would have done had the patentees obtained the limited rights given them by Section 103. In my judgment, Sub-section 2 of Section

Digitized by Google

103 has been read as part and parcel of the whole section. I do not think it was intended to extend the rights of a patentee who chose in this country not to come and avail himself of special provisions in the Act. It is true that at the date the patent in this case is obtained there was no difference to be made in the form of application for the patent, whether the applicant was applying for the limited rights under Section 103 or the more extensive rights, and it has been suggested that the patentees in this case have intended to obtain the limited rights given by Section 103. In my judgment the date of the patent is conclusive. If there has been any mistake, it is a mistake of the patentees themselves. It was for them, if they wished to avail themselves of the benefits of Section 103, to take care they obtained the proper form of patent; and even if it were not their fault, it was their misfortune, or the plaintiffs' misfortune, and as the same result arises it appears to me, therefore, that the plaintiffs cannot avail themselves of the protection of Section 103. The patentees in this case ran their risk for all I know, and it is probable they were not aware and had no reason to believe there had been any prior publication in this country of their invention in any form or shape, and that being so they decided to obtain, and did obtain, the full rights, and chose deliberately not to take the lesser rights which they might have obtained under Section 103. In my opinion it was never intended by Sub-section 2 of Section 103 to apply Sub-section 2 to all cases of patents where the patentee had previously obtained a patent in a foreign country, but only apply it to the general provisions of Section 103 to cases where the patentees wished to avail themselves of the privileges given by that section. This judgment of mine decides the action, but the evidence has been gone into with regard to the second point of it, and it is necessary, on the question of costs, or at any rate advisable, having heard the evidence, and having the point fully before me, I should also decide the second point, which is one of some nicety, that is, the question of infringement. The key to the decision of this part of the case lies in considering what it was that the patentees in this case meant. To judge that rightly, full consideration should be given to the state of the tanning trade at that time. The original method of tanning, the old method, may be called a stationary method. The disadvantages attending that system was that it took a long time to properly tan the skins. It was found that to improve the rapidity of the process, motion was essential, a continual freshening whereby the liquor could be brought more continuously and uniformly in contact with the skins, and hence arose what may be called the second step in the tanning process, and which I might well call the dynamical process, the process by which between the liquor and the skins motion was produced by artificial means. In the course of time several means were discovered for producing such motion between the skins and the liquor, some of which had special advantages, some of which were more acceptable to certain tanners than others, and several of which were patented. Then came what I gather from the whole evidence was, to the tanning trade at any rate, considered a very great improvement, and certainly it was one which was patented, that is, the system which, on the whole evidence before me, I understand to be meant by the rotatory drum. In that case the liquor and the hides were all put inside a revolving cask or drum, which had pegs or other means by which, in the interior of the revolving cask or drum, the hides were from time to time lifted up, plashed down or, as it has been termed, churned about in the liquor. That was considered by the tanning trade in its effect and operation a very considerable improvement. It had certainly, I gather from the evidence, particular advantages which it possessed over all its rivals. So far as I can gather from the evidence, the splashing or churning was of a particular character; it bent the skins about, and the effect of that was to render the skins supple. Whatever may be the process you are pursuing, to practical tanners the result was in any case that it did improve tanning and shorten the process. Tanning, like many other processes, is one about which it is difficult to say that in each case you can indicate clearly and precisely what it is that operates to make the tanning good or speedy. It might be very difficult to point out why one machine does the work better than another machine, but that was the position of the tanning trade when this patent I have before me was patented, subject to one more observation I must make as to the state of electricity. Electricity had been previously known as a means of improving tanning by shortening the period of tanning. Prior to the date of the plaintiffs' patent it had only been applied to what I have described as the stationary method of tanning; it had not been applied to any of the various methods which I have described as dynamical tanning. Then comes the plaintiffs' patent. What did the patentees patent? It is conceivable, though I think there would have been difficulties in the way—it is conceivable that the patentees, if they had chosen, might have patented the application of electricity to all the various methods of what I have called dynamical. It is clear that if they had done so their patent would have run a great risk of attack, even if they had not extended it quite so far as that. The question is, what did they do? That depends on the construction of the patent. In my judgment it is clear that both by the provisional and the final specification, and from the description of the invention in the French patent, that the only combination claimed was a combination of electricity applied to tanning as affected in rotating drums, drums containing the hides and tanning liquor. The words are the same in both the provisional and complete specifications, and in my judgment it is clear, knowing the state of the tanning trade at that time, that they chose, whether deliberately or not I am not concerned with, to limit their patent to the well-known drum in which the hides and the liquor are contained. When that point is arrived at, the rest of the case becomes comparatively simple. I have only to consider whether what the defendant is doing here is applying electricity to that well-known method of tanning by the rotating drum I have mentioned, or is using the rotating drum colourably or substantially. In my judgment, on the whole evidence this is not. The evidence on the subject stands thus:—The plaintiffs produced several scientific witnesses of eminence, but they only produced one practical tanner. I do not intend in this judgment to go through the evidence in detail. The conclusion I have come to with regard to the plaintiffs' scientific evidence is that when carefully considered it only amounted to this. As scientific men, chiefly electricians, they knew that the reason why the plaintiffs' invention succeeded, and had shortened the period of tanning, was because of the simultaneity of the application of electricity to hides in motion in liquor, however that motion was affected. Knowing that, they then assume that this is the plaintiffs' invention or the patentee's, and, moreover, that the patent is for that invention, and on that footing they say in effect that what the defendant is doing is something substantially the same or equivalent to what the plaintiffs set forth in their invention, and they would clearly be right, if they were right in the point that plaintiffs' patent was for the brain invention that I have indicated. Prof. Silvanus Thompson, in answer to a question put by the Court—for plaintiffs' counsel did not direct the attention of the witnesses to this point of the case—said, "I should call S. P. T. 1"—that is to say, the round model which was one of the two forms of the defendant's—"a rotating drum for purposes of producing motion as between the hides and the liquor." That is to say, motion generally, but only for that purpose, so that Prof. Silvanus Thompson, thinking about the motion of hides and liquor generally would consider that a drum for that purpose. But even for that purpose he would not call S. P. T. 2, which was the other form with which the defendant was tanning, a rotating drum at all. Another witness of the plaintiffs, Mr. Swinburne, said that the hides in defendant's machine received different treatment to those in the plaintiffs', but he considered the two processes as mechanical equivalents. That is the plaintiffs' testimony. The only practical tanner is Mr. Blackmore, whose evidence in itself was almost fatal to the plaintiffs'. The only practical tanner the plaintiffs bring forward was almost shocked at the idea that S. P. T. 1 and S. P. T. 2 could be said to be the same kind of machine as S. P. T. 3, which was the plaintiffs' machine. In a practical tanning sense he said they would not work at all. That is the plaintiffs evidence. I need not refer in detail to the defendant's evidence; it negatives the idea which has been suggested on behalf of the plaintiffs that what the defendant is doing is applying electricity to tanning by means of a rotatory drum. In my judgment it is not a mechanical equivalent for a rotatory drum. In one sense, and in the sense in which the plaintiffs' scientific witnesses use the expression, it is a mechanical equivalent for producing motion generally if that was what the Court had to consider; it is not a mechanical equivalent for the purpose of tanning, and especially tanning by which is well understood by a rotatory drum. Neither in my judgment is it a colourable difference, nor can it be said to be a well-known equivalent to produce the same result in the sense in which that expression has been used. Bearing in mind what I have said as to what the patent of the plaintiffs' is, in my judgment the defendants are not infringing this patent; they would possibly have infringed the patent if it had been for the extended process referred to by the plaintiffs, and it had been patented for that. That is not the case, and the plaintiffs' action, therefore, fails on both points, and must be dismissed with the usual result.

Upon an application for costs on the higher scale,

Mr. JUSTICE ROMER refused the application, but directed that the costs of the motion for an injunction, if not provided for, should be costs in the action.

---

## Schoetensack v. Heyl.

This was an action, which came on on the 14th inst., before Mr. Justice Mathew and a special jury, to recover two sums of £500 and £50 paid by plaintiff to defendant, on the ground that plaintiff was induced to pay the same by defendant's fraudulent representations.

Mr. Kemp, Q.C., and Mr. Ashton were for the plaintiff; Mr. Bigham, Q.C., and Mr. E. Harrison for the defendant.

The plaintiff's case, as opened by counsel, was shortly that in April last he became acquainted with the defendant, who introduced to his notice a certain compound which he had invented, and which was to be used for the purpose of covering cables, instead of the indiarubber at present in general use. On account of its low price the profits would be large, as large a profit as 60 per cent. being probable. The plaintiff formed a good opinion of the invention, and thought a company might be formed to work the United States patents. This view was shared by the defendant, who was willing to give plaintiff an option of purchasing his rights. Plaintiff, however, was anxious to know if the invention was likely to have any commercial value, and asked defendant if the matter was still in an experimental stage, or if orders were being given. Defendant assured him that certain orders had been received, and that amongst others he had the promise of a large order from a Mr. Gray, of the India Rubber, Gutta Percha, and Telegraph Works Company in London. An agreement was then proposed, and on the next occasion of the parties meeting the defendant said he had a verbal order for 50 tons of his compound from Mr. Gray. On the faith of that statement, and that defendant said the material was past the experimental stage, plaintiff was induced to enter into an agreement with the defendant and pay him the sum of £500, and in addition a further sum of £50 to bring his cousin Dr. Heyl from America to assist him. Matters went on until the month of June when a second agreement was proposed, but defendant declined to sign it, and finding that defendant in fact had no order for 50 tons, and that the compound was only in fact being experimented with, he commenced this action.

Mr. GEORGE SCHOETENSACK, of 17, Gracechurch-street, examined, said he was the plaintiff, and that in April last defendant was introduced to him by a Mr. Schultze. But for the statement by the defendant that he had an order from Mr. Gray for 50 tons, and that his compound was no longer in a merely experimental stage, he would never have paid the £500, nor the £50 to bring over Dr. Heyl. The agreement was signed on April 16th. The order was a verbal one, but he pressed defendant to get it in

Digitized by Google

writing. On May 21st, however, he saw a letter written by Mr. Gray to the defendant, from which he gathered that the India Rubber Company were only experimenting with defendant's compounds.

Cross-examined by Mr. BIGHAM, Q.C.—As soon as he saw defendant he formed the idea of forming a company to take up the patent. He did not remember taking any steps to prepare a prospectus. The prospectus of the Anglo-American High Voltage Compound Company, capital £100,000 was one he had prepared to work the defendant's invention. A Mr. Nightingale found the money with him and formed a syndicate. He had wired to Heyl on May 7th desiring him to wire to the India Rubber Company to send their order at once, or it could not be executed. When he sent that message he did believe an order had then been actually given. The only reason why, when on May 21st he found out that the Company were only experimenting with the compound, he did not charge the defendant with fraud, was that his friends thought it better to wait and see what course events would take. June 19th was the first charge made in writing, and on that day a writ was issued, but he had been "cool" in his manner to defendant since he saw the letter of May 21st, although he was negotiating other patents with him during that period. It was the fact that he was to pay all preliminary expenses, but it was untrue that he had paid the £500 for the option, and that it was to be the defendant's in any event, whether the Company was formed or not.

Mr. NIGHTINGALE, a bedding manufacturer, examined, said he was plaintiff's partner in the matter.

Cross-examined by Mr. BIGHAM, Q.C.: He was only an amateur electrician, and had not much technical knowledge of cables or the compounds used to coat them; but nowadays every educated man had some knowledge on the subject.

The defendant, GEORGE EDWARD HEYL, in his evidence, denied entirely that he had ever spoken to the plaintiff of an order, verbal or otherwise, for 50 tons from Mr. Gray. All he told plaintiff was that Mr. Gray had given him two orders of half a ton each, presumably for the purpose of experimenting on cables.

Cross-examined by Mr. KEMP, Q.C.: He had been pressed by plaintiff to get a written order from Mr. Gray, but that, he understood, was for purposes of the prospectus. It was not to get a written order for what he had said Mr. Gray had given him verbally. Mr. Gray had not, in fact, given him any large order, nor had he ever represented to anyone that he had done so.

Counsel on either side having addressed the jury,

Mr. JUSTICE MATHEW summed up, and commented on the gravity of the charge made by plaintiff against defendant. It was certainly most curious that two business men like plaintiff and Nightingale, dealing with matters which they could have had all put in writing, when they came to enter into the contract with defendant, did not put a word in as to the conditions on which the £500 was payable.

The jury immediately found a verdict for defendant.

Judgment accordingly.

## CORRESPONDENCE.

### ELECTRIC AND MAGNETIC THEORIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With regard to your note to my letter (p. 340), permit me to say that I have read and studied with close attention everything that has come in my way on these subjects, as well as witnessed and examined such experiments as are within my reach. This study, and my intention to keep thoroughly up to date, is largely the cause of the delay in issuing the third edition of my "Electricity," good part of which has been printed some time since. I have read Dr. Lodge's book, to which you refer me, more than once, and have just run over it again. I find in it nothing whatever which explains the fashionable adoption of these theories, no single line to show that ordinary matter does not cover the ground, and will not explain the whole. Dr. Lodge's book is most interesting; it is filled with ingenious hypotheses and excellent illustrations of their imaginary working out. But that is all; and what I ask for is, not hypotheses as to what the ether can do if it possesses certain properties, but some sort of evidence that it does possess them.

A reference to your Vol. XIV., p. 150, first column, will explain why I invite "so high an authority as Mr. Heaviside" to furnish this, when about to work the theories out for our advantage. He there says:—"Ether is a very wonderful thing. It may exist only in the imaginations of the wise, being invented and endowed with properties to suit their hypotheses: but we cannot do without it." Then he appears to be overwhelmed by the horrid suspicion that this is really the truth, that these "properties" are mere ghosts, and exclaims, "What vanity is this the philosophers are striving after? Is it not 'science falsely so called!'" Surely I may justly inquire how this ghost has been laid, and the perfect faith attained, which is expressed § 5, p. 258.

As myself one of the "anti-mathematicians," against whom Mr. Heaviside directs such heavy blows, p. 330, I may as well explain that they fall harmless. I know of no one, who can be fairly called capable or intelligent, who says the things which are attacked: none such could doubt the high value of mathematics. What is objected to is the constant practice of mathematicians, who having applied all their powers to a mere guess (or in more dignified terms, an hypothesis), proffer their results as "facts" or proved truths. The "mill" illustration, which I have used more than once, means the same thing as the old proverb, that no amount of the most perfect machinery can produce a silk purse out of a sow's ear. The developments of a guess have no more real value, let them be couched in ever so elaborate a formula, than the original guess. Now the ether itself is a hypothesis (may be of wise men, and possibly the mathematicians cannot do without it); its properties are deliberately invented in order to enable it to get round some of the difficult parts of nature. Well, we anti-mathematicians see and say that the mathematical development of them in no way proves their existence, and Mr. Heaviside admits this to all intents in § 10.

Now you tell me in reply to my showing that matter does actully make the vibrations attributed to the ether, that to transmit them it must "be about a thousand million times more rigid than steel; no known form of matter would suffice." This is one evidence of the mischief done by inventing imaginary properties of ether instead of studying the real properties of matter. What is rigidity but some strong attraction among the ultimate particles? Well, I quote Dr. Lodge: "The force between two atoms is a trillion times greater than that of gravity at the earth's surface." Surely we have here something to work at along with the actually known vibrations of those atoms. Just think: we have an exhausted vacuum tube; it contains two things, myriads of millions of gaseous atoms, which we know a great deal about, and (probably) ether, of which we know nothing at all. If we have to do a little hypothesis, which is likeliest to have this rigidity, the matter or the ether? At any rate, we may surely attribute it as justly to one as the other. And here let me say that Dr. Lodge remarks as to ether, "the assuredness with which it is experimented on." I should be grateful for reference to the records; as yet I am only surprised at the assuredness with which improved assertions about it are made and obediently accepted, even although Sir W. Thomson himself says as to them, "Alas, we are only led on to inscrutable difficulties."

I contrast with these assertions and hypotheses the true scientific work shown in Prof. Crookes' address, and the admirable series of experimental demonstrations, where he carries us almost into the ether itself, and yet shows that the despised "common matter" is the source of all the phenomena. In all that fine address I only notice the word "ether" once, and that in reference to the transmission of light, a field which it has long occupied, and in which we may leave it free occupation, at all events as regards space outside matter.—Yours &c.,

JOHN T. SPRAGUE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In answer to Mr. Sprague's request (p. 340), I would willingly do what he wishes if I could. But I must take exception to his initial statement. I have myself spoken plainly enough:—"As the subject is intrinsically a mathematical one, I shall not scruple to employ the appropriate mathematical methods when required" (p. 258). And I am afraid that if I am to get on at all, the employment must be very frequent. I believe, however, that many who will take the trouble to study (rather than read like a novel) will be able not only to understand, but also to learn to use the appropriate mathematics themselves. It is not meant to make difficult, but to make easy, when one has found how to use it.

I am certainly a little surprised at Mr. Sprague's attitude towards the theory of propagation in time through the ether. Perhaps, however, it would somewhat facilitate matters if Mr. Sprague would conceive of the ether as a kind of matter. We

Digitized by Google

know very little about it, but I certainly think propagation in time through something we choose to call ether has been demonstrated for electrical disturbances.—Yours, &c.,

January 17, 1891. OLIVER HEAVISIDE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I, too, shall become a fossil! Were it not for the mention of my name by Mr. J. T. Sprague, in his letter on p. 340 of your current issue, I would not for a moment intervene between him and Mr. Heaviside, whose views he opposes. But as I see he has not understood what I have said on a former occasion, and attributes to me views that are certainly not mine, I ask permission to occupy your columns for a brief space.

Mr. Sprague says that I have referred to a large class as "half-educated" electricians, called so "because they have not surrendered the teachings of experiment, the belief that Ohm's law represents actual facts of nature, and the faith that electric currents are conveyed by the 'so-called conductor.'" Belief and faith are in themselves no part of science. Even if they were, the passage which I have quoted from Mr. Sprague's letter is a most grotesque and inverted representation of my own views.

Let me deal with the three points separately. First, they are called "half-educated" electricians because "they have not surrendered the teachings of experiment." On the contrary, it is because the teachings of experiment in the hands of Faraday proved that the medium surrounding the so-called conductors of the current, is affected by the flow of the current, that I, following Maxwell, and Poynting, and Heaviside, am compelled to take into consideration not simply the wires, but also the medium by which they are surrounded, and to inquire how far the medium is concerned in the transference of energy. If I did not thus follow the teachings of experiment, but remained wilfully blind to the experimental facts, I should be worse than a half-educated electrician who did not know that there were any such facts.

Secondly, they have not surrendered "the belief that Ohm's law represents actual facts of nature." Nor have I, nor has Mr. Heaviside, nor has Prof. Poynting. We all hold that Ohm's law does truly represent actual facts of nature. Not all the facts of nature. Mr. Sprague will readily admit that Ohm's law does not represent the facts of gravity or of static electricity. It does not profess to represent these facts. Neither does it represent the facts about spark discharges, or about currents that are rapidly varying their strength: it does not profess to do so. Dr. Ohm, who first propounded it, expressly propounded it as a law to represent the facts of electric currents *which are flowing steadily*. Only a half-educated electrician would dream of applying a law that is true for steady currents to currents that are not steady, and to which the law in its usual form does not, in fact, apply. I shall come back to this matter presently.

Thirdly, they have not surrendered "the faith that electric currents are conveyed by the 'so-called conductor.'" Nor have I, though with me it is not faith but demonstrated truth, and the teachings of experiment have compelled me in following Faraday and Poynting to modify what I was at one time taught to understand the meaning to be attached to the words "electric currents." I don't in the least object to a half-educated or a whole-educated electrician still saying that the conductor conducts the current. But if he goes on either to say or to imply that the *energy* is transferred along the wire, and not across the medium, then he fails to understand the inner significance of those facts about the surrounding medium, the discovery of which was begun by Faraday and has been continued down to the present day. It is the teaching of these facts of nature as to the part played by the medium in conveying the energy laterally into or out of the conductor, which the half educated electrician too often fails to apprehend.

I now come back to Ohm's law, the law governing the flow of steady currents. Does Mr. Sprague pretend that Ohm's law, pure and simple, is applicable to alternating currents? If he takes an electro-magnet, the resistance of which is, say, 5 ohms, and applies to it an alternating electromotive force of 100 volts, as measured by a Cardew's voltmeter, does he mean to imply that the current which, as calculated by Ohm's law, ought to be 20 amperes, will be, in fact, 20 amperes? And is he prepared to maintain that Ohm's law is applicable to currents just at starting, whilst still in what Continental electricians call its "variable period"?

With respect to the transfer of energy laterally through the medium, into or out of a conductor, surely Mr. Sprague does not intend to fly in the face of facts. Will he maintain that in the case of the induction of a current in a closed circuit, on turning on a current in a neighbouring circuit, the energy is *not* transferred out of one circuit and into the other, laterally to the wires? Or is he prepared to say that when there is induction between one part of a circuit and another part of the same circuit, the energy transferred from one part of the circuit to the other part of the same circuit, is not transferred through the surrounding medium? Is the lateral transfer of energy across the medium a fact, or is it not?

No one regrets more than I, that in defence of scientific progress I should have to cross swords with Mr. Sprague, from whose writings twenty years ago I learned many things. I little thought then that the time would come when I should have to plead with one who then was so far ahead of the current science of his time, that he should not now throw the weight of his authority against the more modern views which are the outcome of, and, as I hold, logical and legitimate deductions from, the facts relating to the part played by the medium in the propagation of electric actions from one point to another.

The harm that is done to progress by the dead weight of old and inadequate notions is truly deplorable. Books like those of Lardner, which forty years ago were in the forefront of science, are now simply a curse to it. Even Fleming Jenkins' handbook, which twenty years ago came as a revelation to those electricians who were not cable-engineers, is doing harm by the presence in it of statements and inferences now known to be incorrect. And my own little text-book of ten years ago, though the attempt has been made in successive editions, as far as the exigencies of printing from stereotype plates would permit, to keep it up to date, is deplorably behind the time, and must either be rewritten or cast aside as a bar to progress. And now, when I find my former mentor, Mr. Sprague, for whose independence of thought and sterling worth I have always had and shall ever have the most sincere esteem, dropping down from the position of pioneer to that of pessimist, I shudder to think of the time when *I, too, shall become a fossil.*—Yours, &c., SILVANUS P. THOMPSON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am glad to see that Mr. J. T. Sprague has taken the Queen's shilling, as Mr. Huxley puts it, in favour of what may be perhaps called "the old views" of electric and magnetic action, although what change of view has occurred has been really more of the nature of development than of revolution; because hitherto the so-called "new views" have been accepted with but little discussion or comment, and that is never satisfactory. The best service one can do to a true theory after its promulgation is to pick holes in it or suggest a rival one, for by that means one finds out of what metal it is made. Mr. Sprague long ago arrived by his own methods and insight at various true ideas concerning electrostatics, at a time when the ordinary text-books were very much at sea; and if he gives us the benefit of his critical acumen, untrained in recent advances though it may be, especially if he can divert Mr. Heaviside from tirades against "anti-mathematicians," and get him to give us either some more solid investigation or else some vivid explanation, he will be doing good service.—Yours, &c., OLIVER J. LODGE.

## THE LONDON COUNTY COUNCIL AND TECHNICAL EDUCATION.

The Special Committee of the London County Council, appointed in October last to consider the subject of the application of any further receipts from the new taxes on beer and spirits, with express reference to the question whether any, and, if any, what proportion of such further amount as might be received should be applied to technical education, have just issued their report, and recommend—

(1.) That the sum to be received from the beer and spirit duties on account of the current financial year over and above the £140,000 which has been placed to the credit account of the general county account, and which is estimated to be about £23,000, be devoted to the furtherance of technical education in London.

(2.) That the money be given to the following institutions in the form of capital grants to be expended (save where specially ordered otherwise) in buildings, fittings, apparatus, or plant to be used exclusively, or at any rate mainly, for the purpose of imparting technical education to persons of the artisan or labouring classes :—

| Institution. | | Amount of Grant. |
|---|---|---|
| Borough-road Polytechnic | | £4,000 |
| Battersea Polytechnic | | 4,000 |
| Chelsea Polytechnic | Conditionally upon the schemes being carried out within two years | 2,500 |
| St. Pancras Polytechnic | | 3,000 |
| Holloway Polytechnic | | 3,000 |
| Regent-street Polytechnic | | 4,000 |
| Working Men's College | | 500 |
| Joint Committee of School Board, City and Guilds Institute, and Drapers' Company (having due regard to 52 and 53 Vic., cap. 76, sec. 1 (1) | | 1,000 |
| National School of Cookery (for training teachers) | | 500 |
| University Extension Scheme (to organise lectures for artisans at low rates of admission) | | 500 |

Finally, the Committee recommend that a sum not to exceed the estimated produce of a 1d. rate be devoted to technical education in London ; and that a standing committee on technical education be appointed. The Committee's report will be considered by the London County Council at its next meeting.

## TRADE NOTES AND NOTICES.

ERRATUM.—In our trade note of last week we notified that the Woodhouse and Rawson Electrical Supply Company were continuing the manufacture and supplies of incandescent lamps made under licence from the "Brush" Electric Light Company. This should read, the "British" Electric Light Company.

KEY'S ELECTRIC COMPANY (LIMITED).—This Company announce that they have opened at Nos. 122 and 124, Charing Cross-road, Oxford-street, London, W.C., show-rooms and warehouses for the sale of electrical machinery, fittings and apparatus, and further announce that they have been appointed representatives in this country of the well-known Berlin firm, the Allgemeine Elektricitäts Gesellschaft. They have on view in the new show-rooms a large quantity of electric light fittings, instruments, motors, &c. Further particulars will be found in our advertisement pages.

ELECTRIC LIGHTING OF WYNYARD.—One of the largest private house electric light installations in England will be that at Wynyard, Lord Londonderry's country seat, in Durham. This installation, the contract for which has recently been given to Messrs. Drake and Gorham, will comprise 753 incandescent lamps, together with a steam power electric gererating plant of the necessary large dimensions. Mr. A. A. Campbell Swinton has been appointed consulting engineer to superintend the work on Lord Londonderry's behalf.

SANITAS COMPANY (LIMITED).—We have received from this Company a complete list of their well known manufactures. A large quantity of articles similar to those made by the Sanitas Company must be in general use in large engineering establishments, and we can speak from experience, covering a long period, of the value of the Sanitas Company's specialities where large bodies of workmen are employed.

## COMPANIES' MEETINGS & REPORTS.

### The National Telephone Company (Limited).

A meeting of the shareholders of this Company was held on Wednesday at the City Terminus Hotel, Cannon-street, Mr. Frederick Richard Leyland presiding.

The CHAIRMAN said: Gentlemen, this is not one of our usual meetings, where the Directors have to place before the shareholders certain resolutions to be passed. It is really more in the nature of a conference which the Directors desired to have with the shareholders, so as to explain to them what is the present position of the Company now that the first of their key or master patents has expired. At first we thought that we might, and that it would be our duty to, intimate our views to the shareholders by means of a circular, but it would have had to be a very elaborate and very detailed one, and we could not depend upon which way the different sections of shareholders would regard it. Consequently, we came to the conclusion that the best and wisest thing to do was to meet our shareholders face to face and place our views before them, and thus to have the advantage of any suggestions or remarks on the subject that no doubt will be made by gentlemen in this room. With these few preliminary observations, I will go first into the accounts as made up to the 31st October last, that is, for the first six months of the current year. They have not been audited, and there is no necessity, I think, to audit them ; but I can give you now what the result is for the six months. The accounts show that the Company has earned in those six months a net profit of £108,170 19s. 11d. This sum, together with £11,113. 9s. 7d., which was brought from last accounts, leaves an amount of £119,284. 9s. 6d. standing to the credit of profit and loss account on October 31st. Out of that sum we have paid you an interim dividend amounting to £62,973, and we had then on hand £56,311. This sum, together with the profits that will be made in the second six months of the year, you will have to dispose of at the next annual general meeting. Now I have put before you the bare figures of the result of the six months working, and I think you will agree with me that they show a very satisfactory advance indeed on the profits of last year. I dare say you all remember pretty well what the results were then. I have got in my hand and no doubt you have all got it at your offices, the statement of accounts of April, 1890. The revenue account there for the twelve months showed a profit, carried to net revenue, of £185,754. The same profit on that revenue account for the six months to Oct. 31, 1890 is £104,763. Now, if you divide the £185,754 for the twelve months by half you would have then about £92,874, but instead of that you have got, as I have said, for the six months I am dealing with £104,000. Now what does that show? Last year, you remember, we called up a sum of £260,000 by an issue of 52,000 new ordinary shares. We strongly recommended that course to the shareholders as being a wise thing, and we assure them that our conviction was that new capital would give you just as good a profit as the old capital had previously done. That has turned out to be the case. The capital on April 30, 1890, was £2,204,000. The result of revenue account showed a profit of £185,754, which means a percentage of about 8¼. We did not divide that. We were content—and I think wisely—with 6 per cent. dividend, the other 2¼ being carried, under the advice of the Board, principally to reserve. Now with reference to this issue of £260,000 of fresh capital, what does the increase of revenue amount to? The increase of the profit on revenue account was £11,891. What does that give you on that £260,000? It is as nearly as possible 8¼ per cent., just the same as you had on the larger capital. I think that is a desirable thing, because the bigger your Company is the stronger and more impregnable you are against competition. What, then, happened after October 31st, the date to which these accounts are made up? Up to December 31st the rates remained the same, and there was the ordinary normal increase of the business, and we can see clearly enough that for the two months—that is, from October to December—the ratio of increase in the profits will be maintained, and I think slightly exceeded. But after that date, on January 1st, when the first key patent that I spoke of expired, we thought it a wise thing (although the second key patent does not expire until July, 1891, seven months after) we thought it the wisest thing was to make a reduction of rates to subscribers, and to make it at once, just as if both patents had expired. The first result of that is, of course, that the revenue is reduced. But, on the other hand, there is one thing that we have to take into account, and that is, that the reduction of rates we believe will bring on to the system a great number of additional subscribers who would not otherwise have come on ; and in that way we shall gradually recoup the whole of that loss, and, I think, more quickly than you may imagine. Now let us see what the indications are. From April to October, 1890, the increase in the number of subscribers was 1,940. Dividing this by the number of weeks—26 weeks—that would give you an average of about 75 or 76 subscribers per week. Again, what has been the increase in the number of subscribers during the first three weeks of the present month? They amounted to 651. If this rate of progression is continued—and I see no reason why it should not—I feel convinced that it will be but a comparatively short time before the whole of the loss caused by the reduction in our rates will be recouped ; and of one thing I am perfectly certain, you will have an infinitely stronger business. There is no business so strong as a large one that can work economically. As I have said over and over again, I do not think the possession of a monopoly, as we have had now for many years, is an unmixed blessing. Gentlemen, I have now explained the position of the Company from the point of view of its revenue and profit-earning power. I must next deal with it from the point of view of its capital expenditure. In this Company every increase of the business necessarily involves an increased expenditure on capital account. You cannot link up a fresh town ; you cannot even put on an additional exchange without incurring some capital expenditure. It is unavoidable so long as we pursue the policy that we have up to the present always thought to be the best—that is, the policy of extending and developing our business by covering all the available ground. I think that the statement I have made to you, and the figures I have put before you, all point in the same direction—namely, that that policy is a good and safe one, and one that we ought to stick to as being the sheet anchor of this Company. I spoke at length very much in the same sense at our last meeting, and I believe the feeling of the shareholders went thoroughly with what were the views of the Directors on this point. What did we expend then on the first six months on capital account? We expended in that period on the construction of exchange lines, trunk lines, and private lines the large sum of £96,970. A considerable portion of that—about £40,000 or £45,000—consisted of expenditure in linking up different towns in the provinces.

Digitized by Google

I have a list of them here, but I am not going to inflict on you the reading of it, but I may say that the number of them altogether is 244. We have not let the grass grow under our feet. All those towns are now in communication with each other. That is what I believe will prove the salvation of this Company. It must necessarily do so. Any competitor coming into our district can give only a local service, unless he is prepared to spend the enormous amount of money we have spent in linking up nearly all the different towns in the kingdom. Now, I am glad to say, that of that £96,000 we spent the greater portion of it by October 31st, and it is now yielding a very satisfactory and growing revenue. Of course when you link up a town you do not expect next day to have the whole thing in full working order. It is necessarily a gradual operation; but we are so satisfied with the result of that, that we are actively continuing up to the present day on the same lines to cover the ground whenever we can advantageously. Wherever there is a fair chance of getting a suitable revenue we are bringing the towns gradually into communication with our main centres in the different provinces. Well, this is a very big expenditure, and an increasing one. I remember at the last meeting there was one shareholder who got up and suggested that we should not get into debt, but that we should confine our extensions to the amount that we put to the credit of reserve fund. Certainly that is one policy to pursue, but what does it mean? It does not mean covering the ground and developing our business; it means restricting it within very narrow limits. What would be the result of following such a policy? You would find plenty of people who would only be too glad to take the business that you did not care to do yourselves. Well, I for one am not going to advise you to adopt such a policy as that. At the last meeting I spoke on this point, that increased capital must be obtained; and I told you then that the Directors had not made up their minds as to what the best mode of raising that would be; that is to say, by Preference shares or by Debentures. We have since considered the matter thoroughly, and we have come to the conclusion that the best thing for the Company is to raise that money by Debentures. I think it is the cheapest way of doing it, and it avoids many of the complications that must arise with Preference shares. There are two classes of Preference shares, and it would never do to have a third. We should have to make some arrangement for sweeping off the others, and merging the whole into a larger stock, so that, I think, as all the Directors do, that Debentures are preferable. Having come to this conclusion the Board intend under the powers given to them by the Articles of Association to issue perpetual Debenture stock which we think is the best form of issuing it—that is, to issue that Debenture stock from time to time as it is necessary for the purposes of the Company. But we must have a care of one thing, and that is, when we commence to issue these Debentures we must make it part of a very large sum—not necessarily to be issued—but we must make it part of a large creation of Debentures so that any subsequent amount that we may issue will rank equally. There will be no First, Second, and Third Debentures, and all that complication. I propose, and the Board fully considered, and also propose, that we should create as large an amount of the Debenture stock as our Articles of Association authorise us to do. We are limited by the Articles not to exceed one-half of the capital, and I think our wisest course is to create that stock, and issue it as required. As to the first issue, it may be asked how are we to deal with that? In the first instance, when we do issue Debentures, they must be first Debentures. We cannot, as I have said, think of a Second Debenture stock, and we propose that in our first issue we raise enough money to pay off, as we are entitled to do, the existing Debentures, that is, a sum of about £80,000. We will give the holders the option (and many of them I know will be only too glad to avail themselves of it) of taking their Debentures, not in cash but in other Debentures of the Company. I am quite sure it will be a much better position for them to be in to be holders of Debentures in a large stock like that which will certainly be quoted on the Stock Exchange, and largely dealt in, than to be Debenture-holders as they are now in a small issue of £75,000, for which there is neither sale nor purchase. Having dealt with that £80,000, what is the next thing we have to deal with? We have to repay the capital account that £97,000 we spent up to the October 31st last, out of the revenue. That must be replaced, and I think then we ought to hold in hand a sufficient amount to carry us on to the end of this year, so that we shall not be continually coming to you suggesting fresh capital. Fresh capital will have to be raised if this business goes on, unless you make up your minds to relinquish—and I do not think you are likely to do that. We have been working the matter out, and we think that the first issue ought to be something between £300,000 and £350,000. Now I have given you pretty nearly all the main facts of the position. Our view of that position is that it is very favourable, and that it gives, and ought to give, every shareholder great confidence in the future of this Company. The Directors feel it. At the same time I should be glad, and the Board would be glad, to listen to any suggestions and remarks from shareholders. We, in fact, invite them. The position to us seems clear, but it may not be to some of you, and we should all like to hear what the shareholders may have to say on this point, so that we may be able to answer any doubts in their minds, or explain anything that to them may be obscure. There is no resolution to be proposed.

Mr. BIDEN asked what was the proportion of working expenditure to income, and for what term the Debentures were to be issued?

The CHAIRMAN: I think I did state that my view is that a permanent Debenture Stock would be the best thing.

Mr. BIDEN: You think that better than for, say, a period of 21 years?

The CHAIRMAN: I think so; but at the same time I should be glad to listen to anything you have to suggest on the matter.

Mr. CHIPPERFIELD suggested that the list of the 244 towns linked together might be circulated with advantage among the shareholders. He thought they ought to be in possession of this information. He wished to know whether Southampton was one of the towns included in the list.

The CHAIRMAN: It is not in the Company's district. We have, however, covered about three-parts of England already.

Mr. CHIPPERFIELD understood from what had been said that the issue of the new Debentures would be taken up largely by the holders of the existing issues.

The CHAIRMAN: The present Debentures are what are called Perpetual Debenture Stock, and amount to £73,000; but the Company has the right of repaying them at any time they like on the payment of 10 per cent. premium.

Mr. CHIPPERFIELD asked what was the interest paid on the present, and what it was propsed to pay on the new Debentures?

The CHAIRMAN: What is paid on the present is 4½ per cent. What will be paid on the new issue I cannot tell you, but you may depend upon it, we shall get it at as cheap a rate as we can. As regards the suggestion about the list, we shall have it printed and circulated.

Mr. WATSON desired to know what untoward consequences would result from the expiration of the second patent.

The CHAIRMAN: The first result when the patent expires is that all the world can use it. Up to the present nobody could interfere with us. We had practically a monopoly. When these two patents expire everybody can interfere with us. But what has been the line of policy we have pursued? I explained at the last meeting, and I will explain it again now, it has been to cover the ground, to be the man in possession, and to bring your working expenses down as much as possible. The bigger the business the less must be the proportion of working expenditure per subscriber. That is the line of action we have been steadily pursuing, and that is what I have always recommended. What the ultimate result of it may be neither I nor anyone can foresee. I feel confident that the indications are strong that the loss we suffer in the first instance by a reduction in our rate will be recouped to us by an accession of additional business, but I cannot prophecy more. You are as able to judge for yourselves as I am. I have got every confidence, and so have the Board.

Mr. WATSON asked what was the danger, so far as the Directors knew, of the possibility of rival companies being established?

The CHAIRMAN: There is none that we have heard of except in the case of one company that is now starting in Manchester, and they have experienced difficulty in getting their money up, which is only £40,000.

Mr. SALTER said there had been considerable expenditure in connection with through-speaking between Manchester and London. Might he ask whether that was likely to turn out satisfactorily? What was the reduction that had been made in the rate?

The CHAIRMAN: In the main towns, such as Manchester, Liverpool, Glasgow, and Bradford, the reduction has been from £15 to £10.

Mr. SALTER: What about London?

The CHAIRMAN: We have made no reduction in London on the exchange tariff, and I think there is some reason for it. The rate the people in the provinces pay is for a radius of one mile—in some cases even lower. The radius of London is very much greater than that, in addition to which the expenses in the Metropolis are enormous. They are double what they are in any other place. It is impossible to get out of that. I think that this is a sufficient reason for the difference between London and the provinces being kept up. I think, however, the main thing with regard to London is not so much a reduction of the rate as an increase of efficiency. That is what we have been driving at. We have had our hands full. We have done a great deal, but a great deal still remains to be accomplished. That, in my view, is the main thing with regard to London, not the reduction of the rate.

Mr. SALTER: Has the through-speaking turned out satisfactorily?

The CHAIRMAN: The amount of revenue that we have derived from that up to the present time is only small, but we have had several inquiries about it, and I am disposed to think that we shall have to consider whether that is not one way of making this line a good profit-earning line. The inquiries that we have had are from people who have a large business connection in Manchester, London, and Liverpool, who wish to have a line to themselves, or, at any rate, between certain hours of the day; or, as others put it, a combination of two or three or four individuals want to have a line during the whole of the day time between them. Then there is the question of the night time, when there is a good deal of correspondence for the newspapers, which require the line at night. The number of calls from London to Liverpool, Manchester, Leeds, Birmingham, and other places has not been very large up to the present time, but it will grow.

Mr. ELLIS asked whether the poles or supports carrying the existing wires from Birmingham to Manchester and elsewhere would suffice to carry a large addition of wires.

The CHAIRMAN: Certainly.

Mr. ELLIS: So that any reasonable number of new subscribers could be put on?

The CHAIRMAN: Quite so.

Mr. LOWE asked how the reserve was invested.

The CHAIRMAN: I told you at the last meeting that we came to the conclusion to invest our reserve fund in our business, and so we did. The view that we took of it was that it would be impolitic to raise capital and keep our money in reserve in some good security not subject to fluctuations, and get only 2½ to 3 per cent. for it. We could not see the policy of calling up capital which would cost us 4 per cent., for the sake of putting money into a security which would yield us 3 per cent.

Mr. FALCKE asked whether by a reduction of their rate in London they would not secure a large accession of business?

The CHAIRMAN: I must say that is not my impression. I think a more important thing is to get the service efficient, which will take some time and a considerable amount of money.

Digitized by Google

The CHAIRMAN, in answer to Mr. Biden, said that the working expenses in proportion to the gross revenue for the past six months came to exactly the same as it did last year—namely, 40 per cent. Last year your total income was £364,704, and in the half-year ended April 30th it was £205,678. The Secretary has worked out the expenses, and he tells me they come to 40 per cent. in each case.

After some further remarks from Mr. BIDEN,

The CHAIRMAN, in reply, said: Everybody knows perfectly well how this Company was amalgamated. It was amalgamated on the basis of the market value of the three companies—or rather on the basis of one-sixth less, which we were obliged to adopt for some reasons connected with the Post Office. Now, you call that a heavy capital. I have read some newspaper articles, and the writers call it watering the capital. That was the real way in which the amalgamation was brought about. How could you expect to amalgamate on what had been paid on the shares originally? The shares had a well-ascertained value on the market, and that was not only goodwill. Take the case of the United. Their capital was £500,000, but, like wise men when their business was profitable, they did not divide their profits up to the hilt. They put large amounts to the reserve, to the debit of their revenue account, for depreciation, and all this they invested in the business. Do you think the shareholders did not know that quite as well as other people? You may shake your head, but that is the fact. You take our 40 per cent. of working expenditure, and you compare that with the railways, but I ask what in the name of fortune has this Company to do with railways? They are two entirely different businesses. You must consider this, that that 40 per cent. must be of course a higher percentage when it comes on to a lower tariff. We have been having monopoly prices up to the present, but that time has gone by now. You say that other companies can do the work cheaper. I do not think they can, and I believe the best plan is to let them find that out for themselves. You say that the London people grumble at the high rates. I have heard a good deal of dissatisfaction expressed, and I have had many complaints made; in fact, I have invited people to send in complaints, and I have looked into them as far as I personally could, but I have not found people grumbling at our high rate; it has always been at the inefficiency of the service. That is my experience. Yours is different, but I must really go by my own. You talk of its being a desirable thing to have 3, 5, and 7 years' agreements. That is what we have been going for all the time, and we have got plenty of them. I will not publish in the papers our revenue from week to week, or give a monthly account of our expenditure, unless I am told to do so by the shareholders.

A SHAREHOLDER asked whether they were on good terms with the Post Office?

The CHAIRMAN: Yes; very good. The soreness there was on the subject of the amalgamation has worn off, and we are on very much better terms.

Dr. GALE thought that no company could stand against the National Telephone Company so long as they continued to pursue the policy hitherto adopted.

Mr. LEEK (Manchester) endorsed the statement of the previous speaker.

Mr. RIDSDALE advised them to introduce a Bill into Parliament giving them statutory powers.

The CHAIRMAN: As the Company increases the volume of its business that will become a matter of necessity, especially in London. We have felt that, and it is a matter that is now engrossing our attention. The fact is we are about to draw up a Bill, and we ought to try and pave the way as much as we can for its favourable reception when it gets into the House. If any of the shareholders here have any influence in that direction, and will exercise it, it will materially benefit the Company.

On the motion of Mr. CHIPPERFIELD a vote of thanks was passed to the Chairman, and the proceedings terminated.

---

## The Eastern Telegraph Company (Limited).

The 37th half-yearly general meeting of this Company was held on Thursday, the 15th January, at Winchester House, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. George Draper) having read the notice convening the meeting, and the minutes of the last meeting, which were confirmed,

The CHAIRMAN said: Gentlemen, before entering upon the business of the day, I think I may fairly congratulate you on the year that has passed as being a successful year for the Company, and also to express the hope that the year we have entered upon may be a prosperous one for the Company, all our associates, and all those interested in it. As usual, I will go into some of the points in our report, so that we may draw the leading figures from them.

Our revenue, from all sources, for the half-year ended September, 1890, amounted to £352,873, as against £351,014 in the corresponding period of the previous year, showing an increase of £1,859. Analysing this revenue, we find a falling off in our receipts for telegrams exchanged with South Africa, of over £5,000. In addition to this, the dividend that we have had on our investment in the South African Company is £5,900 less than in the corresponding six months, so that we may put down a loss of £11,000, as attributable to the collapse of speculation in gold mining and diamond shares in South Africa. Our Egyptian, Greek, and Turkish traffic also shows a decline of some £1,600, but this decrease is made up by a growth of over £12,000 in our Indian, Trans-Indian, and Spanish traffic, and by increased dividends on our other investments of £2,000. For the six months we show a gross increase of £1,859. The total working expenses for the half-year to September, 1890, amounted to £91,723, as against £87,730, or an increase of £3,993, the details of which are as follows:—General expenses in London were £8.502, against £8,410, or an increase of £92. Working expenses at stations amounted to £68,435, against £64,712, or an increase of £3,723, the principal item being £2,657 in the salaries of our foreign staff. A number of our more advanced probationers were transferred to the staff at Porthcurnow, Gibraltar, Malta, and Zante, in connection with the full working of the triplicate cable and the increase in the number of messages carried. Additional probationers were engaged to fill the vacancies thus caused. This, together with additional pay granted to some of the staff, accounts for the increase. There is also an increase of £639 in repairs to stations, buildings, &c., the most important repair being at Alexandria, where rather extensive alterations and improvements are being carried out. The amount written off for depreciation of cable stock is £802 more than in the corresponding period, owing to our having a larger stock of spare cable. The amount carried to maintenance ships reserve fund is only £2,500, as against £5,000 in the previous half-year, the other portion having been contributed by those telegraph companies who have hired our ships during the half-year. Expenses in connection with the Paris Telegraph Conference, which appear in our revenue account this time, amounting to £981, is an exceptional item, but a very necessary one, and I think I may safely say that full value has been received for this expenditure. Expenditure attending repairs and renewals of cables amounted to £31,477, against £49,634, or a decrease of £18,157. Full details of the expenses of the ships, &c., and value of cable used will be found on reference to abstract C of the accounts. The amount of cable used on repairs during the half-year was exceptionally small, and our ships have been several times employed in cable laying and repairing work for other companies. The credits derived from this source have been applied in reduction of the ships' expenses, &c.

The summary of the half-year's revenue account is as follows:—Increase in gross revenue and amount brought forward from last half-year, £3,369; decrease in total expenses, £13,678. We are, therefore, after providing for all expenses and interest charges against revenue, able to pay the usual interim dividend at the rate of 5 per cent. per annum, to carry forward to next half-year's account £78,195, against £61,151, or £17,044 more than in the corresponding period of 1889.

Now, gentlemen, I think that that condensed statement of our affairs must be a very satisfactory one to you all. (Hear, hear.)

I cannot sit down without saying a further word on the telegraphic system, although I have said so much on previous occasions. Still, telegraphy is a never-sleeping, ever-moving system, and even when we come here in the morning, probably before we have been an hour in the business, we find a cable has been broken or a cable has been repaired. It has become so much now a matter of form with us that the anxious days we used to have are no longer experienced. But we have always to look forward to such a day as this, when we have to come and account for our doings to you for the previous six months, and to produce to you your usual, I hope, satisfactory dividend. That is our ambition, and so far we have been fairly able to realise it.

I think there are times when we may with perfect propriety give a short condensed review of our position. I may say to-day that we are in a thoroughly satisfactory state. We have not increased our capital to any extent, but yet we have laid down cables that cost nearly a million sterling, which we have taken from the reserves and revenue. If you have not got very large dividends, you have got behind you so much strength in the dividend you are getting that the value of your shares, as appears by the market quotations, is increased in consequence of that great backing.

I think I may mention to you what has been done in a silent yet very satisfactory way. We have duplicated, triplicated, and quadrupled many of the cables in our system. In all that additional strength which we have been giving, we have been carrying out the policy we have always observed, of being ahead of the requirements of the public.

I have indicated to you on previous occasions that that was our strength; and when we found that a new departure was going to take place with reference to the Australian colonies—an endeavour on their part which was very strongly supported by the companies—to reduce the rate to South and West Australia from 9s. 4d. to 4s., we felt that if that was to be successful we must practically double the amount of traffic over our system. That traffic has to come largely over this system, and consequently it would never have done for us to be behind. We are now about to lay a third cable from Aden to Bombay, which, with the cable we laid last year in the Red Sea, will enable us to carry satisfactorily this large increase of traffic from Australasia which we are looking forward to. I might give the sections of the cables that we have duplicated, triplicated, and quadrupled, for there is a list of them here, but I need not trouble you with such details. It will be sufficient for me to say that there are twelve which have been duplicated, one triplicated, and two have been quadrupled, so that you see we have carried out what I have always said. No single line of cable is to be relied upon. You must have a duplicated system, and if you can have a triplicated or quadrupled system you are so much stronger still.

I have referred in my remarks to the African traffic not being good. Those who have been watching over this "dark continent" and the spurt that is taking place there, with the speculation that has been going on, never expected that that would last for ever. But it is not likely to die, and we see now that there is evidence of that movement again. There is no doubt at all that as that feature develops so will our traffic move forward.

Now I think I have pretty nearly exhausted all I had intended to say to you, namely, that the extensions that are going on—and we are doing them without issuing new capital to a very large extent—we are doing them to meet a decided demand, and in incurring this expenditure we are adding very materially to the value of your property. I hope we shall be able to continue such dividends as we have been giving you, add

Digitized by Google

to our Reserve, and occasionally increase our bonus. With these remarks, I beg to move the adoption of the report.

The MARQUIS OF TWEEDDALE: I beg to second the resolution.

The CHAIRMAN: The resolution is as follows:—

"*That the report and accounts of the Directors to the 30th September, 1890, submitted to this meeting be, and the same are hereby, received and adopted.*"

That has been moved by myself and seconded by Lord Tweeddale, the Deputy-Chairman. If any gentleman desires to make any remark or to put any question, I shall be very glad to answer him as usual. If not, I shall put the resolution to the meeting. (The Chairman then put the resolution to the meeting, which was carried unanimously). The next resolution is one which affects me personally, so that it must be dealt with by the Deputy-Chairman.

The MARQUIS OF TWEEDDALE: The resolution I have to move is:—

"*That Sir John Pender, K.C.M.G., who now retires, be and is hereby re-elected a Director of the Company.*"

I do not think it is necessary for me to add one single word to that resolution. Every one present must have recognised long ago the admirable manner, the conspicuous ability with which Sir John Pender has conducted the affairs of this Company, and, therefore, I am quite sure that the shareholders will accord their unanimous support to this resolution.

Mr. GEORGE GARDEN NICOL; I have great pleasure in seconding the resolution. Associated as I have been with Sir John Pender from the commencement of this Company, I can bear willing testimony to the attention, tact, ability, and energy which he has shown in the conduct of its affairs, and I am sure you will agree with me that he is the right man in the right place. I hope he may be long spared to preside over this Company.

The MARQUIS of TWEEDDALE put the motion to the meeting in the usual way, and it was carried unanimously.

The CHAIRMAN: I thank you very warmly for again returning me as a Director of this Company. It is a Board that has worked almost as one man. I believe that each of the members of the Board is proud to occupy a position on it. It is a Board respecting which we have interests apart from making money. We have a belief that in the work we are doing, we are doing something to leave the world a little better, stronger, and more united than it was before. The next duty I have to perform is a very pleasant one, namely, to propose the following resolution:—

"*That the Marquis of Tweeddale, who now retires, be and he is hereby re-elected a Director of the Company.*"

Now, gentlemen, Lord Tweeddale has been associated with these Companies from their inception. He has not been a fancy Director, as a great many people have been disposed to say regarding men of high position and title. He has been a working Director—a man with a good head and great energy; and, as has been shown since he became associated with us, many other people are very desirous of getting the benefit of his energy in institutions larger than this, or quite as large, and I therefore move with great pleasure this resolution.

Mr. J. DENISON PENDER: I have great pleasure in seconding the resolution.

The CHAIRMAN put the motion in the usual way, and it was carried unanimously.

The MARQUIS OF TWEEDDALE: I have to thank you very warmly for the kind way in which you have received this resolution.

Mr. HURST, a Shareholder: I have had the honour of being a shareholder in this Company for a great many years, and I certainly never felt more satisfied or such satisfaction as I do at the present time. The auditors have done their work exceedingly well, and I am convinced that with regard to the Eastern Company we must all feel that we have got a most excellent and valuable security, one of the safest and best that I know of. We can sleep quietly in our beds about it, and feel satisfied that we shall have our dividend paid as has been the case in the past. I was extremely pleased to hear one thing which must be gratifying to you all—that even an increased dividend is almost anticipated by the Chairman. That is very satisfactory! As I have said, the auditors have done their work exceedingly well, and I may add that in a great Company like this the work of the auditors is not a trifling affair, but a matter requiring great consideration and great attention, and you must have competent and first-rate men to enable you to do the work in the manner in which it should be done. You have all read the accounts and examined them carefully, and I think everyone will agree with me that this work has been done well. The whole of the work of the Company, in fact, has been carried on in so admirable a manner that I think few companies in this kingdom or the world can compare with it. It is a great and wonderful concern, and such a one that, when I became a shareholder, I hardly expected that its ramifications could have been carried on so well and so successfully as they have been. I will now read the resolution which I have risen to propose:—

"*That Mr. Henry Dever and Messrs. Welton, Jones, and Company, both of whom now retire, be and they are hereby re-elected auditors of the Company for the current year at a remuneration of £100 each.*"

I have great pleasure in proposing that resolution.

Mr. MUIR: I beg to second that.

Dr. WALLER: I had risen to second this resolution. I have to make one observation, and only one, on the meeting to-day, and that is that it is so pleasant. I do not mean to refer to the eloquence of our Chairman—that is a matter which we all know. The eloquence I admire to-day is one that is generally unusual, that is, the eloquence of silence in the body of the hall. It is golden. We are reduced very often to listen to very disagreeable discussions. To-day there has been nothing but the most eloquent silence prevailing.

The CHAIRMAN: This resolution has been proposed and seconded.

The motion was then put, and carried unanimously.

Mr. GRIFFITH: I am sorry that my partner is not present to hear the very courteous remarks of the shareholders in proposing this resolution, but I will convey them to him, and I beg to return to you on his behalf our best thanks.

The CHAIRMAN: That finishes the business of the meeting, and I am very much obliged to you for giving us your company.

Mr. BURT: It is not often that I have the pleasure of sitting on this side of the table. As you have mentioned my name, I think I may take the opportunity of proposing a vote of thanks to the Chairman. There are few gentlemen here who have heard more speeches from the Chairman than I have, and I agree with the gentlemen on the other side, that I have never heard a more eloquent speech than I have to-day by the Chairman and one that could be more satisfactory to you. Moreover, there is this satisfaction: When one hears a good speech there is often very little truth in it, but so far as I know what the Chairman has told us to-day is simple solid fact, and we have to rejoice that this Company is in the position it is, that the Board is constituted as it is, and that we have a gentleman like Sir John Pender in the chair.

The resolution being seconded,

Mr. BURT put the motion in the usual way, and it was carried unanimously.

The CHAIRMAN: Gentlemen, it is a source of great satisfaction to me to find a good feeling growing in the body of the hall in favour of the people behind this table. It is quite true that we have had a great deal to bear sometimes; but conscious that the duty we are performing was a right and straight one, we have never felt aggrieved—we knew it was all going right. It has been a hobby with me for many years this—submarine telegraphy, and it was equally a hobby with my colleagues. So long as we continue to work as one man you may be sure that it will continue to be a success. It is a great and growing concern, a concern which must grow as the world grows; and the more people get accustomed to telegraphy the less will they be able to do without it. It was one of the luxuries of life, it is now a necessity, and it will be largely extended as the world grows richer. When I see you again I shall have visited some of our distant stations, in all probability. I think it is a wise and proper thing to look occasionally into those places beyond the sea. We know that a great deal depends upon those places being properly and well conducted. It is encouraging to our young men on those stations to see someone representing the Company visiting the stations, and that is going to be my mission the next two months. I beg to thank you, gentlemen, again.

The proceedings then terminated.

---

## The Direct United States Cable Company (Limited).

The twenty-seventh ordinary general meeting of this Company was held at Winchester House, 50, Old Broad-street, on the 16th inst., under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. T. Finnis) read the notice convening the meeting, and the minutes of the last ordinary general meeting.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, I will follow up the practice which I have observed on many previous occasions, when I have had the pleasure of meeting you, of going over the figures of our report, because really on the present occasion that is almost all I have to refer to. The year has been rather an eventful one in some respects, commercially, both here and in America. At the same time, I think that England has come out of it in a marvellously satisfactory way, and let me hope that being the beginning of a new year we are making a new departure in commerce, and that such departure may be largely beneficial to our telegraph system generally. There is a saying—very often a true one—that no news is good news, and as I have nothing very striking to say to you as to what has been done last year, you may take it that it has been fairly satisfactory, though not so satifactory as I could wish to see. I should like to see us go back to our 5 per cent. dividend, and the only way that I can see of doing so is by encouraging the development of telegraphy between the old and the new world, and in that way we shall get a substantial return. The money earned from the Atlantic traffic to-day is about the same in amount that it was when it was conducted at a very much higher tariff. But other companies have come in to compete for and to share that traffic with us, and it is now the cleverest fellow that is likely to get the largest amount of it. I may say that the Company which I have the honour to represent has done its work very well, and has earned its fair share of the traffic, and as long as the gentlemen who sit here with me remain here, we shall not be backward in that respect. At the same time, people entertain rather peculiar notions with regard to these things. It is sometimes said "that new brooms sweep clean;" and we have to contend against these new brooms, and we have often to show them that, with experience, the old broom will very often beat the new one. With these remarks I will now refer to the figures showing our working during the last six months. The revenue for the half-year to December 31st, after deducting out-payments, amounted to £43,347; and the working and other expenses, including income tax, but excluding cost of repairs, absorbed £17,556, leaving a balance of £25,791 as the net profit of the half-year, making, with £968 brought forward from the previous half-year, a total of £26,759, which has been appropriated as follows:- Interim dividend of 3s. 6d. per share for the quarter to September 30th last, £10,624; interim dividend of 3s. 6d. per share to December 31st, £10,624; balance carried forward, £5,511. The revenue for the half-year shows an increase of £990, equal to 2¼ per cent. as compared with that for the correspond

Digitized by Google

ing period of 1889. The development of the traffic, though slow, appears to be progressive. The working expenses in London have been so very nearly the same as in the corresponding period that a comparison of the items need not be made. The total (as shown by abstract "A") is £45 less than in 1889. The expenses at stations (as shown by abstract "B") exhibit an increase of £1,856, due to two causes: Firstly, and chiefly, to our having now to bear the whole of the expenses of the New York Office, instead of one-third only of those expenses as in 1889, as explained to the general meeting in July last; and secondly, to the prosecution of an active canvass for business on the Continent of Europe, as well as in the United Kingdom and New York and Boston, accounting for the greater portion of the increase in the item of printing, stationery, and advertising. The reserve fund, after being debited with £1,629 for cost of repairs, and credited with £4,307 for interest on the investments, now stands at £252,678. The investments, as heretofore, continue to be worth much more than the figure of cost at which they stand in the balance-sheet. Gentlemen, these are the items to which I desire to refer, so that they may be impressed on your minds. I began my remarks by what I should probably have said at the present moment; but what I want to point out is this, that in July last, and this day twelve months, I went so exhaustively into the position of this Company, that when I read my two speeches this morning, I was rather astonished that I had so completely taken up every point with regard to the position of the Company, its past, its present, and its future, and I satisfied myself that the best thing I could do, after having read these figures to you, was simply to tell you that you must wait for six months in order that I might get something new to mention. In the meantime you are going to get the same dividend that you received last year, and which has been paid for the last two or three years. We hope that it will continue, and I should be very much disappointed if it went backwards. But you may rest assured of this, that it will require all our exertions to keep it up because the competition at the present moment between the different companies is very keen indeed, and everyone is doing his best to secure for his own company a fair share of the current traffic. I am a strong believer myself in the increase of telegraphy generally, and therefore I feel satisfied, looking at the part we are playing in submarine telegraphy, that we shall not lose any opportunity of maintaining our position, and if we can get, by a little extra exertion, a little more than our neighbours, you may depend upon it we shall do so. With these remarks I beg to move,

"*That the report of the Directors, dated January 5, 1891, together with the statement of accounts to December 31, 1890, annexed thereto, be and the same are hereby received and adopted.*"

Mr. W. FORD seconded the motion.

A SHAREHOLDER suggested that instead of the item of messages in the revenue account being lumped with the remark "after deducting the rent of wires," the two should be separately shown.

The CHAIRMAN said that the matter would be considered, and if, having regard to their arrangements with other companies, they could act upon the suggestion, they might do so.

Another SHAREHOLDER asked whether the Chairman could give them any idea as to the probable result, favourable or otherwise, of the litigation referred to in the sixth paragraph of the Directors' report (the lawsuit between the Anglo-American Company and the French Company).

Mr. JACKSON said he had intended to ask a question on the same subject. "The capture of the French cable" he regarded as one of the most scandalous incidents in Atlantic telegraphy, and it was the outcome, in his opinion, if not of what was fraudulent, of an intrigue towards which he believed the French people and the French courts would show no favour. He could not help expressing the opinion that there had been a supineness on the part of the "pool" directors in not bringing to an issue the litigation which had been so long pending, the existence of which he believed neutralised all the efforts of the associated Companies to share in the normal increase of the traffic.

The CHAIRMAN: Probably had I been standing in Mr. Jackson's place I might have used stronger language than he has, but I think I need not remind you, as you must know it, that the conduct of this affair is entirely in the hands of the Anglo - American Company. They have been working at it from the very beginning. The suit is in their name. We have, however, been constantly watching, and the other day, when I was in Paris, I took the liberty of talking to the lawyer who is conducting the case for them. I said I was interested in the case, though I had no right to interfere: but looking at it from our point of view, which enabled me to take a correct view of it, I said I thought that it was about the most scandalous case that ever came under my observation. I spoke very strongly, and knowing the excitable tendencies of the French people, when one speaks as I spoke, to resent such remarks, I almost congratulated myself at the end of the interview that I was not engaged in an affair of honour. However, Mr. Jackson, if you are going to the Anglo-American Company's meeting, which will be held shortly, you may, perhaps, be able to elicit the information which I am not in a position to give to you. I think I have spoken to you, Mr. Jackson, pretty plainly on this matter, but I differ from you in the conclusion you have come to. I do not think that that case is the cause of our paying 3½ per cent. instead of 5 per cent. Not at all. But I should like to see it removed, and I should like to have blotted out from the escutcheon of submarine telegraph companies the transaction which has given rise to the suit in question.

On the motion of Mr. JOHN NEWTON, seconded by Mr. JACKSON, a vote of thanks to the Chairman and Directors was then passed.

The CHAIRMAN: It is always a great satisfaction to me and my colleagues to be complimented by our shareholders. Time was when they were very severe upon us, but they are now just to us, when we have come to a time like this. We all feel that there is a want of a larger dividend. I am not one of those who say that you are getting all that you ought to get. I think in submarine telegraphy you ought to get more, as I have always said; but you may depend upon it that where there is introduced into a trade, however great and however growing, a new power in conducting the traffic—where the very people themselves who are interested have become such experts in coding and reducing the number of words required to carry on their business—you have little conception of the difficulty we have in getting out of them a fair return for the facilities which we provide for them. It is a very striking scientific question. While the trade is growing there is a growing knowledge of converting this electrical power more and more to their own purposes. We have all that to contend with. It is not a plain sailing business. We have also science to contend with, we have all the ingenuity of merchants to contend with, and we have the competition of one company with the other to contend with so as to hold our own, so that you see we do not lie on a bed of roses. I thank you very much on behalf of myself and colleagues for the vote of thanks which you have so kindly passed.

The proceedings then terminated.

---

## Anglo-American Telegraph Company.

The following is the report of the Directors of this Company, to be presented to the ordinary general half-yearly meeting of the proprietors, to be held at Winchester House, Old Broad-street, E.C., on Friday the 30th inst., at 2 o'clock:—

1. The total receipts from July 1 to December 31, 1800, including the balance of £2,793. 18s. 4d. brought forward from the last account, are

PATENT

SILICIUM BRONZE AND SILICIUM COPPER WIRE.

The best for overhead Telephone and Telegraph Lines,

AND ALL ELECTRICAL PURPOSES.

Hard Drawn High Conductivity Copper Wire.

ROLLED AND DRAWN PHOSPHOR BRONZE.

PHOSPHOR BRONZE — VULCAN — PHOSPHOR — DURO METAL

PHOSPHOR BRONZE BEARINGS, BUSHES, AND OTHER PARTS OF ELECTRICAL MACHINERY

SOLE PROPRIETORS of the British, Indian and Colonial Patents,

THE PHOSPHOR BRONZE COMPANY (Limited),

87, Sumner Street, Southwark, London, S.E.

WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

Digitized by Google

estimated at £161,9C6. 14s. 2d. This amount, however, is subject to revision, ~~as the~~ lawsuit between this Company and the Paris and New York Telegraph Company is still pending before the Council of State. The traffic receipts show an increase of £3,027 as compared with the corresponding period of last year.

2. The total expenses of the half-year, including repair of cables, &c., as shown by the revenue account, amount to £56,142. 6s. 11d.

3. Interim dividends of 15s. per cent. on the ordinary stock, and £1. 10s. per cent. on the Preferred Stock, were paid on November 1st last absorbing £52,5C0, leaving a balance of £53,344. 7s. 3d., out of which the Directors recommend the proprietors to declare final dividends of 15s. per cent. on the Ordinary Stock, and £1 10s. per cent. on the Preferred Stock, amounting to £52,500, making a total distribution for the year ended the 31st December, 1890, of £2. 17s. 6d. per cent. on the Ordinary Stock, and £5 15s. per cent. on the Preferred Stock, leaving £844. 7s. 3d. to be carried forward to the next account.

4. The Company's repairing s.s. "Minia" has been engaged during the past half-year in the repair of the Northern Placentia cable and was previously chartered to the Direct United States Cable Company. The vessel has been undergoing necessary repairs, and not being available when a serious fault appeared in the Brest-St. Pierre Cable, near Brest, the Directors took advantage of the Eastern Telegraph company's s.s. "Mirror" being in the neighbourhood to obtain her services, and the repair was promptly and satisfactorily effected by that ship.

5. The Company's cables and land lines are in good working order.

6. The Directors greatly regret to announce the resignation through failing health of their valued colleague, Viscount Monck, who has occupied the position of Chairman, with great advantage to the Company, since 1873. The Board unanimously elected the Marquis of Tweeddale as Chairman, and Mr. F. A. Bevan as Deputy-Chairman. The vacancy on the direction created by the retirement of Lord Monck has been filled by the appointment by the Board of Sir Albert J. Leppoc Cappel, K.C.I.E., formerly Director-General of Telegraphs in India.

7. In accordance with the Articles of Association, two Directors of the Company, the Marquis of Tweeddale and Cyrus W. Field, Esq., retire at this meeting, and, being eligible, offer themselves for re-election. Mr. Joshua Dean and Mr. John Gane, F.C.A., the auditors, retire, and offer themselves for re-election.

## NEW COMPANIES REGISTERED.

**NORTH-EASTERN TELEPHONE COMPANY (LIMITED.)**—This Company was registered on the 14th inst. with a capital of £4,600, in £1 shares, to carry on the business of a telephone company, and to adopt an unregistered agreement of 23rd ult. with the Primary Syndicate. The subscribers are:—J. V. Walton, Wilton, Durham, lead smelter; W. M. Angus, Newcastle-on-Tyne, merchant; G. Angus, Newcastle-on-Tyne, merchant; T. D. Challoner, Newcastle on-Tyne, chartered accountant; E. Fawcus, Newcastle-on-Tyne, merchant; J. Monks, Aden Cottage, Durham; E. S. Hindmarsh, Gateshead, merchant. The Directors of the Primary Syndicate (Limited) are appointed *ex-officio* Directors of this Company. Solicitor, Mr. H. W. Sample, St. Nicholas Chambers, Newcastle.

## CITY NOTES, &c.

**ANGLO-AMERICAN TELEGRAPH COMPANY.**—The Board of Directors of this Company have resolved to recommend to the proprietors at the next half-yearly general meeting of the Company, to be held on the 30th January next, the declaration of the following dividends:—(1) A balance dividend of 15s. per cent. upon the Ordinary Consolidated Stock for the year ending December 31, 1890; (2) a balance dividend of £1. 10s. per cent. upon the Preferred Stock for the year ending December 31, 1890, both payable on January 31st next, less income tax, to the stockholders registered on the books of the Company on the 13th inst. After paying the foregoing dividends there will be an estimated balance of £844 to be carried forward to the next account. The above dividends, together with those already paid, will amount to £2. 17s. 6d. per cent. on the Ordinary Consolidated Stock, and £5. 15s. per cent. on the Preferred Stock for the year 1890. The register of transfers will be closed from January 16th to the January 30th.

**ALLCHIN, LINNELL & CO. (LIMITED).**—A winding-up order has been made against this Company.

**BRAZILIAN SUBMARINE TELEGRAPH COMPANY.**—The receipts of this Company for the week ended January 16th amounted to £6,099. The Coupons of this Company's Five per Cent. Debentures (1884 issue), due January 31st, will be paid on and after that date at the Alliance Bank, Bartholomew-lane, London, E.C. Coupons must be left at the Bank three clear days for examination.

**CITY AND SOUTH LONDON RAILWAY COMPANY.**—The receipts of this Company for the week ended January 17th amounted to £758.

**COMMERCIAL CABLE COMPANY.**—This Company has opened a new office at 8, Foster-square, Bradford, and also at 37, Albert-square, Dundee.

**EASTERN TELEGRAPH COMPANY (LIMITED).**—This Company notify that the coupons on their Five per Cent. Debentures, due February 2nd next, will be paid on and after that date at the Banking House of Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street, E.C. Coupons should be left at the bank three clear days for examination.

**EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).**—This Company announce the payment by warrants on February 2nd next of interest for the half-year ending January 31st, on their Four per Cent. Mortgage Debentures. The Transfer Books will be closed from January 28th to February 2nd, both days inclusive.

**ELMORE'S AUSTRO-HUNGARIAN COMPANY.**—A meeting of this Company will be held at the Cannon-street Hotel, E.C., to-day, at 12 o'clock.

**MANGANESE BRONZE AND BRASS COMPANY (LIMITED).**—The Directors have declared an interim dividend of 8s. per share for the half-year ended December 31st last, payable on March 2nd next.

**MAXIM-WESTON ELECTRIC COMPANY.**—A meeting of this Company was held yesterday at Winchester House, E.C., but we are unable to provide a report, as our representative was informed that the proceedings were private, and that no reporters would be admitted.

**NEW COMPANY.**—The *Weiner Zeitung* announces that the Austro-Hungarian Banking Company has received the requisite sanction for the establishment of the General Austrian Electricity Company, with offices and works in Vienna.

**PERSONAL.**—Mr. H. A. Bell has been appointed Managing Director of Bell's Asbestos Company, Limited.

**STOCK EXCHANGE.**—Application has been made to the committee to appoint a settling day in, and to grant a quotation to, £320,000 Four per Cent. Mortgage Debenture Stock of the Eastern Extension, Australasia, and China Telegraph Company (Limited); and to allow Elmore's French Patent Copper Depositing Company (Limited), shares Nos. 1 to 66,750 to be quoted in the Official List.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY.**—The traffic receipts of this Company for the week ending January 16, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,935.

**WEST INDIA AND PANAMA TELEGRAPH COMPANY.**—The traffic receipts for the half-month ended Jan. 15th were £2,596, as compared with £3,C01 for the corresponding period of 1890, showing a decrease of £405.

**WHITE'S ASBESTOS (LIMITED).**—At an extraordinary general meeting of the shareholders of this Company, held on Thursday, a resolution was passed for winding up the Company voluntarily.

# THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

**VULCANISED FIBRE,**

PATENTED.

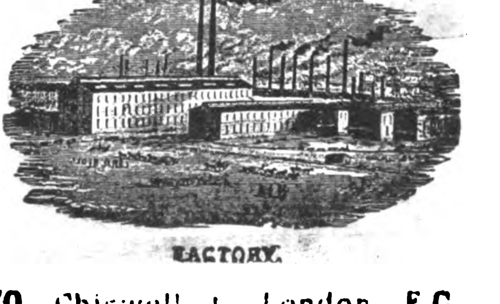
This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.



FACTORY.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per

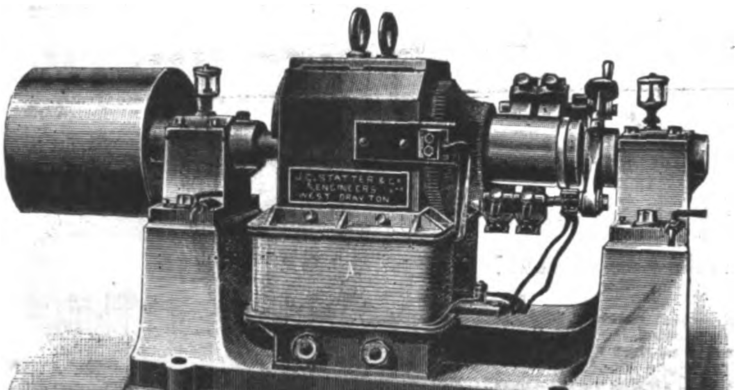
# IMPROVEMENTS IN DYNAMOS.



## STATTER-BRUNTON DYNAMO.

**The latest design in the market, made with all the advantages of the latest scientific knowledge and the highest mechanical skill.**

The woodcut represents our B TYPE DYNAMO. A most efficient machine, working noiselessly, and without sparking or overheating; is highly finished and well proportioned. The output is so rated in our Catalogue that the machines may be worked very much in excess of their stated full output for short periods.

**STOCK SIZES UP TO 77 KILOWATTS.**
**MACHINES BUILT TO 500 KILOWATTS.**

**THE ELECTRICAL ENGINEERING CORPORATION, LIMITED,**
(STATTER'S) (UNITED.)

68, Victoria Street, London, S.W. WORKS:—ALLIANCE ENGINEERING WORKS, WEST DRAYTON, NEAR LONDON.

// THE ELECTRICIAN:
A WEEKLY ILLUSTRATED JOURNAL OF
ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.
No. 663.—Vol. XXVI. FRIDAY, JANUARY 30, 1891. Price Fourpence.

# NOTES.

Although the paper read by General Webber at the last meeting of the Institution of Electrical Engineers did not contain much matter of interest, it has certainly provided several subjects for discussion, and if the speakers will confine their remarks to some of the side issues raised, the debate may be of considerable value. We have not thought it necessary to reproduce the intricate diagram of the automatic switch, or the scarcely less complicated description of it. It is very unlikely that the Chelsea system will ever be largely imitated, and if something similar were to be attempted elsewhere the whole affair would probably be re-designed. There is a limit to automaticity in any mechanical arrangement, and this limit appears to have been considerably overstepped in the present case. It is difficult to imagine an engineer trusting to the accumulation of gas from a "master cell" to cause a series of complicated reversals and reconnections through the agency of magnets and local circuits. Dr. Fleming has thoughtfully pointed out that a device by which the services of a man can be dispensed with, may be valued by the capitalized sum of his wage. But this takes no account of risk, and when the safety of a station and the continuity of its supply are dependent upon automatic working, attended with such an amazing complication, it is obvious that engineers must be ever present to look after the whole of the automatic arrangements, indeed we have heard that a "master" block of wood is found to be very useful for holding up the switch until it is considered that the proper time has come for it to act.

Two appeals, each for £50,000, have been made simultaneously by University College and by King's College to meet the increasing demands of education, particularly in modern science and experimental research. These are supported by well-known names, to which Lord Salisbury's was subsequently added. Each college can point to excellent laboratories and valuable apparatus and appliances; but of late years technical education of the higher order has made such strides that these old-established foundations are in danger of being left behind, and of crystallising in that pitiable way to which all educational men and institutions are so liable. If University College and King's College are to hold their own in competing with the Central and the Finsbury Institutes of the City and Guilds of London in both science and engineering, neither the laboratory and traditions of Prof. Kennedy, nor the liberality of Lady Siemens and Messrs. Davey, Paxman, and Co. will suffice. These colleges, if they are to keep in the front rank, must have the personal influence of such teachers as those who are to be found in the rival lecture rooms. Given good men, the colleges will easily maintain their reputation, but the best men will not devote their whole time to the labour, and cut themselves off from all other professional work, unless they receive a reasonable renumeration; nor will they be attracted by the facilities for private research, which is the chief inducement in some cases, unless the laboratories be properly equipped. Now that the City and Guilds of London Institutes are so thoroughly successful, each in their own line, and Polytechnics are being proposed in different parts of London, we hope that the effort to maintain and develop the teaching of science and of engineering at Gower-street and the Strand will meet with the success it deserves.

The remarkable accession to the number of telephone subscribers consequent upon the reduction of the subscription is most encouraging to the policy which the National Telephone Company have now avowed their intention of pursuing. By attracting all the subscribers possible, and covering all the ground, they may confidently defy any competitor that has the temerity to enter the field against them. Now that their patents are virtually extinct they are in the position of some of the more powerful lines of railway, liable in theory to competition, but practically exempt. From the Post Office there comes no sound of warning; and it would seem that for another six years at least the great Telephone Companies will be free to make as much money as they can, and extend their operations as widely as they choose. We are confirmed in the opinion that the trunk lines which are being everywhere erected to link the systems together into a united whole, will not pay for their construction: but they will give a certain valuable prestige, and with good management may indirectly attract customers to the remunerative local sections.

In connection with this response on the part of the provincial towns to the Company's reduction of rates, the Chairman was probably right in the reason he assigned for not conceding a similar reduction to the far wider area of the Metropolis. But we think we could supply another and a more sufficient reason, namely, that cheapening the service in London would have no effect on the number of subscribers so long as the working remains what it is. Evidently provincial towns are far better

Digitized by Google

served; and if London had some of the Company's spare capital expended upon it, there is no reason to doubt that the improvement would be met by a similar generous inrush of subscribers.

PART 90 of the *Journal* of the Institution of Electrical Engineers is mainly occupied with the lengthy discussion arising in connection with the two papers on accumulator tests made at the Central Institution; but a few abstracts, and a list of the titles of some of the chief electrical papers which have appeared during the last five months are appended. For some years past the number of abstracts printed in the *Journal* has been steadily diminishing, those appearing in the volume just completed numbering little more than half those printed in the volume for 1887. This is to be regretted, as at the present day it is impossible for anyone to keep pace with the enormous mass of current literature, or even to avoid missing papers dealing with his own special branch of work. For this reason a well-chosen series of abstracts of those articles which have not appeared in the common technical papers, accompanied by a fairly full list of the titles of papers which have been printed in the chief English and Foreign Electrical Journals is invaluable; and the *Journal* of the Institution has in this respect set itself to fulfil a very important function. The list actually issued might, however, without much extra trouble have been made more complete; and especially in the case of foreign articles, if references were made, not only to the *Journal* in which the papers were originally printed, but also to the more accessible English journals in which translations have appeared.

THE proposal emanating from our monthly contemporary *Electrical Plant*, that a permanent electrical museum should be formed under the auspices of the Institution of Electrical Engineers, has much to commend it. Had such a museum been founded in the days of GILBERT of Colchester, and had it survived all vicissitudes until the present time, it would be impossible to overrate its value. When it is seen what support the proposal meets with it will be time enough to discuss details; but it is to be hoped that the advocates of this museum have some plan for making it more attractive, and consequently more useful than has hitherto been customary. A dusty, ill-arranged, badly-catalogued collection of miscellaneous electrical apparatus, stowed away in an indifferently lighted, almost inaccessible loft, would, no doubt, be a museum "within the meaning of the Act," but it would most certainly fail to attract. In an out-of-the-way corner of the Birmingham Exhibition of 1889 an old wooden frame was to be seen containing what appeared to be a brass drum and a medley of horseshoe magnets. Nor did reference to the catalogue throw much light on the mystery, which was nothing more or less than the first electro-plating machine ever constructed, and which, although dating as far back as A.D. 1844, was an excellent example of a dynamo with its equipotential armature coils connected in parallel. In a conspicuous position in the Edinburgh Exhibition of last year there was a fine collection of telegraph apparatus shown by the Post Office; the exhibit was both well arranged and well catalogued. A visitor to the Edinburgh Exhibition could scarcely fail to see the Post Office exhibit; while Woolrich's magneto-machine at Birmingham was a mere accidental discovery. It is unnecessary to say which method of exhibiting would tend to make a permanent electrical museum a genuine success.

WITH this issue we present to our readers a map, on the scale of 3½ inches to the mile, showing the streets in which electric supply mains were actually laid up to the beginning of the present month. The great activity of the supply companies of the metropolis is very apparent, though the number of miles of mains does not represent the volume of the business done in the different districts. We had at first hoped to represent the actual position of mains and feeders, but these are in many cases so numerous that it would not have been possible to show them clearly even on a map on a scale two or three times larger; and since few, if any, of the supply companies have as yet finally settled their feeders or systems of mains, it would be premature to deal with these details at present. The Ferranti mains of the London Electric Supply Company are not shown, as they are not used for supply of current to consumers. The four sets, belonging to this company, at present laid, cross the river at Charing Cross.

**Venice.**—Four 80 kilowatt alternators are to be installed for the lighting of Venice. These will supply 7,000 10 candle-power lamps.

**Tivoli.**—According to the *Elektrotechnischer Anzeiger*, the central station being built by the Società Romana di Gaz will be opened on May 1st.

**The Lighting of the City.**—The first portion of the electric lighting cable in the City will, be laid on Tuesday, the 3rd prox. The Lord Mayor, it is hoped, will be present on the occasion.

**Intra.**—A central station is to be built for the electric lighting of Intra, Italy. Power is to be derived from four 150 horse-power turbines, and the alternate current-transformers system will be used.

**Electric Traction at Gera.**—The Allgemeine Elektricitäts Gesellschaft are about to equip an electric tram line at Gera 10km. long. Some 10 cars will be provided, and the Sprague overhead system will be employed.

**Old Students' Association.**—On Saturday, January 24th, a most enjoyable evening was spent at Prof. Perry's house, 31, Brunswick-square, by the members of this association. In all there were about 200 persons present, most of whom were students and their friends.

**A Novel Application of the Duplex Method.**—Duplex working with ordinary Morse instruments has been tried as an experiment on the Bushire-Jask cable, says *Indian Engineering*. The experiment, which seems to have been fairly successful, is due to Mr. Possmann, electrician of the Persian Gulf section.

**The City Commissioners and the Overhead Wires Bill.**—The Commissioners at their last meeting resolved that a petition should be presented to provide, in regard to the London Overhead Wires Bill, against any alterations being made therein prejudicial to the jurisdiction of the local authority.

**Local Authorities and Telephone Wires.**—At a recent meeting of the Worksop Local Board the clerk was instructed to give the National Telephone Company one year's notice to remove the poles now fixed on the Board's roads and property, as no one was benefited by the telephone but private subscribers.

**The London Electric Supply Corporation.**—It is expected that the supply will be re-commenced by the middle of next month. It has been decided to earth the system at Deptford.

Digitized by Google

but the details of the insulation and the requirements of the Board of Trade and of the Post Office are not yet finally settled.

**Cardiff.**—Notices of opposition to the proposed electric lighting Order of the Corporation have been lodged by the Glamorganshire Canal Company, the Bute Docks Company, the Western Counties and South Wales Telephone Company, the Taff Vale Railway Company, and the Cardiff Gas Lighting and Coke Company.

**The Production of Copper in the United States in 1890.**—The production of copper in the United States in 1890 amounted to 124,380 tons, thus far exceeding any previous record, and being 20 per cent. greater than the output in 1889; it now amounts to more than 50 per cent. of the world's total output of this metal in 1889.

**County Councils and Technical Education.**—At a meeting of the Herts County Council on Monday it was decided by a large majority to expend £6,400, received from the beer and spirit tax, in the furtherance of technical education on an equitable basis throughout the county. An amendment proposing to devote the money to the reduction of local taxation was defeated by 32 votes to 17.

**The Clerk-Maxwell Scholarship.** — Candidates for the newly-founded Clerk-Maxwell Scholarship in Experimental Physics are requested to send their names to Prof. Thomson, 6, Scroope-terrace, Cambridge, before February 21st. Each candidate is requested to forward a statement of the original work which, in accordance with the conditions of the tenure of the Scholarship, he would undertake if elected.

**Electric Lighting and Traction in Madras.**—According to *Indian Engineering* a gentleman just arrived from England has submitted a scheme to the President of the Municipal Commission of Madras for lighting the city by electricity and placing electric tramcars in it. He is supposed to be powerfully backed at home, and one of the promoters is already on his way out to negotiate with the authorities concerned.

**The Pacific Cable.**—A Bill was introduced in the United States Senate on Monday sanctioning the incorporation of a Pacific Cable Company, with a capital of $5,000,000, to work a cable between San Francisco, Hawaii, Samoa, and Japan. The Bill provides that the majority of the directors shall be citizens of the United States, and authorises the Treasury to pay the company an annual subsidy of $200,000 for 15 years.

**Lightning Statistics.**—The following figures are taken from the official returns of the thunderstorms observed, and the damages caused by lightning in Belgium, during the years 1884–1888:—

| | 1884. | 1885. | 1886. | 1887. | 1888. |
|---|---|---|---|---|---|
| Persons killed ... | 16 ... | 13 ... | 5 ... | 7 ... | 15 |
| Houses set on fire | 29 ... | 28 ... | 54 ... | 17 ... | 19 |

**Electric Traction in Berlin.**—The Berlin Municipality has lately been approached by the promoters of electric traction, with a view to the extension of electric tramways throughout the city. The Municipality has decided that no concessions will be granted for the construction of high-level street electric railways, or for electric tramways requiring overhead conductors carried on posts, erected either on the horse-roads or footpaths.

**Personal.**—Mr. Drake has sufficiently recovered from his severe accident to enable him to be conveyed home from the Westminster Hospital, and it is hoped that he will in time thoroughly recover from the effects of his fall.——Friends of Major Flood-Page will be glad to learn that he is recovering from the severe indisposition which has confined him to his house for the past six or seven weeks. On inquiry yesterday afternoon we were informed that he was much better.

**The Lane-Fox Patents.**—We are informed that an arrangement has been concluded between the St. James and Pall Mall Electric Light Company and the Lane-Fox Electrical Company, by which the validity of the Lane-Fox distribution patent is specifically acknowledged: a licence is taken out and a royalty paid to the Lane-Fox Electrical Company. We further understand that the Lane-Fox Company is doing all it can to hurry forward the action it has brought against the Kensington and Knightsbridge Company.

**Liverpool.**—A deputation, representing the Liverpool Electric Supply Company, waited upon the Watch Committee at its last weekly meeting to ask permission to extend their area of supply, and to retain the 42 years' clause in the Provisional Order. The committee declined the application. The deputation also asked for an extension of the time allowed in the present area, and this request was likewise rejected. It is, however, expected that a compromise will be come to between the Corporation and the company, on the basis of a 35 years' duration of the company's powers.

**Correction.**—The following corrections should be made in Mr. Kennelly's Paper on Inductance, which appeared in our issues of January 2nd and 9th:—Page 268, 15 lines from end of page, for "tenth" read "hundredth"; p. 269, col. 1, line 10, for "9,778" read "9,978"; p. 306, col. 2, line 1, for "ampere, half" read "absolute unit of current (ten amperes), five times"; same line, for "393," read "3,930"; line 2, for "millihenrys" read "henrys"; line 3, for "per ampere" read "for ten amperes"; line 4, for "11·79" read "11,790"; lines 13 and 15, for "2/30" read "2/3"; line 18, for "0·393" read "3·93."

**Hull.**—At a meeting of the Electric Lighting Committee of the Hull Corporation last week an application was received from Woodhouse and Rawson United for permission to put down an installation on a piece of vacant ground, in Broadley-street, for the purpose of lighting a block of property by electricity. It was decided that intimation should be sent to the applicants to the effect that the committee were not in a position to entertain the matter. It was also decided that a circular should be sent to tradesmen and residents with a view to ascertaining whether they would be disposed to adopt the electric light, if it was introduced by the Local Authority.

**The New York Edison Company.**—A statement recently made by the Edison Electric Illuminating Company of New York to the New York Stock Exchange contains the following comparative statement of earnings:—

| | Years. 1888. | 1889. | 1890. |
|---|---|---|---|
| Gross ... | $226,301 ... | $327,678 ... | $488,595 |
| Operating expenses and taxes. | 110,066 ... | 203,647 ... | 259,517 |
| Net ... | 116,235 ... | 124,031 ... | 229,078 |

These earnings do not include any revenue from the large station in Pearl-street, now in course of erection, or from any considerable part of the additions and extensions recently made to the company's system throughout the city.

**Proposed Extension of the City and South London Railway to Peckham.**—A movement is on foot among some influential residents of Peckham and East Dulwich with the object of obtaining an extension to these districts of the above railway. A largely-signed memorial of inhabitants has been drawn up praying the local authorities to increase the railway accommodation of the district, which, it is complained, is at present far from satisfactory; and the Camberwell Vestry will shortly approach the Directors of the Railway Company with regard to the matter. Should that Company entertain the proposed scheme, it is suggested that their system should be extended from the Elephant and Castle, through the Walworth-road on to Camberwell-green, and thence down the Peckham-road to East Dulwich and Nunhead.

**The Electric Lighting of Railway Carriages.**—On Friday last week a special trial train fitted up with the electric light was run from Dublin to Drogheda, the contract for lighting all the mail trains on the system of the Great Northern Railway Company of Ireland by electricity having been entrusted to the Electrical Engineering Company of Ireland. Should the light prove successful, it will be extended to all trains. There are 18 accumulators provided for each composite carriage, and 5 c.p. lamps are provided. A Brush dynamo, worked by a Stockport gas engine, will be erected at the Amiens-street station to charge the accumulators.

**Telephonic Communication between London and Paris.**—According to a Reuter's telegram of the 24th inst., the French Minister of Commerce is engaged in drawing up the conditions for the working of the telephone service between London and Paris, and it gives the following as the essential points:—The charge for the use of the telephone would be 10fr. for a three-

Digitized by Google

minutes' conversation. This charge would at first be only experimental. The telephone will be available either night or day, and correspondents of the two nations will have the use of the instrument alternately. The telegram concludes with the announcement that "The British authorities on their part will adopt such measures as they may deem fit," which we presume means that the tariff for using the telephone on this side may differ from that given above.

**Bristol.**—The electric lighting committee of the Bristol Town Council have further considered Mr. Preece's report on the scheme for lighting the city. The committee have made arrangements by which a portion of the site for the installation can be entered upon by March 25th; but they have decided to ask Mr. Preece for additional advice as to the style of plant that should be laid down. They have also agreed to add £5,000 to the original estimate on account of the probability of work in respect of the foundations of the site in question being necessary. This will bring the total estimated cost to £60,000; and for this sum the committee believe that an adequate installation can be secured for brilliantly lighting the area contemplated.

**The Hanover-square School of Electrical Engineering.**—The manager of this School, Mr. L. Drugman, informs us that as the result of recent examinations the following students have now obtained the Vellum Certificate of the School:—(A) In Electric Lighting and Power Transmission: Messrs. A. C. D. Crommelin, B.A., J. Finlay, J. F. Irgens, H. Macfarlane, L. Marchetti, F. J. Moffett, B.A., R. J. F. Mostyn, J. W. Parr, P. F. W. Simon, P. J. S. Tiddeman, H. Treherne, L. W. Wild, C. B. Wigg. This examination was conducted by Mr. Gisbert Kapp, and consisted of a paper in Mechanical Engineering, a paper in Electrical Engineering, a *viva-voce*, and Practical Examination and Drawing. (B) In Telegraphy and Telephony, Mr. H. Treherne above-named. This examination was conducted by Mr. H. R. Kempe.

**High Pressure Transmission of Power Experiments.**—Some important experiments were carried out last week at Oerlikon by Mr. Brown with a view of demonstrating to officials of the German telegraph department and others the feasibility of high pressure transmission of power. As we have already announced it is proposed to electrically transmit 300 horse-power from Lauffen-on-Neckar to Frankfort-on-Maine, a distance of 100 miles, in connection with the Frankfort Exhibition, and the Government has been asked to supply the line for that purpose. An artificial line 4½ miles long was employed in these experiments, and pressures of 15,000, 20,000, and 33,000 volts were tried, step-up transformers being used at the transmitting end and step-down transformers at the receiving end. The experiments were carried out during a severe snowstorm.

**Temporary Decrease of Resistance of Badly-conducting Mixtures.**—With reference to the editorial note on p. 350 of our last issue, Mr. S. A. Varley calls our attention to his lightning protectors described at the British Association, 1870. He found that fifty cells would not pass an appreciable current through a mass of finely-divided black lead or wood charcoal, but with two or three hundred cells "the particles arranged themselves by electrical traction, making good electrical contact, and formed a bridge by which the electricity freely passed." On this principle he made lightning bridges, which were used on the Bristol and Exeter Railway, but which were condemned by the Post Office. Mr. Varley appears to be under the impression that his device "acted on similar principles to Prof. Hughes' microphone, which it anticipated, and which proved in practice to be a most efficient lightning protector." Our correspondent entirely misses the interesting part of M. Branly's experiments which are not accounted for by "electrical traction."

**A Severe Test of the Overhead System of Electric Traction.**—Judging by the accounts in the various American technical journals the overhead system of electric traction has stood the test of winter weather better than was anticipated. At Boston the conditions appear to have been particularly severe. Here, on Friday, December 26th, snow began to fall at 8.30 a.m., the temperature being very low, wind very high. By noon the temperature had risen, and remaining high during the afternoon the snow began to thaw. In the evening rain fell until midnight, when the temperature again fell. The system proved equal to the emergency. The only serious delay was on a section where the cars were run at such infrequent intervals as to allow the snow to accumulate on the track between trips, and of course when the snow melted and the rain fell, and the whole afterwards froze, the tracks became seriously obstructed. On all other sections of the systems regular running was maintained by the electric cars.

**The Streatham and Tulse Hill Institute.**—On Thursday evening, the 22nd instant, Mr. Henry Edmunds delivered a lecture before this Society on "The Applications of Electricity." The lecture hall was well filled with an appreciative audience. Various articles illustrating the domestic application of the current to such humble offices as heating irons and boiling water were shown, and several electric motors demonstrated the transmission of power. Mr. Edmunds also exhibited his phonoscope, which renders visible the changes in the diaphragm of a telephone; and also his electrical gyroscope, describing the possibilities of such an instrument. By the courtesy of the National Telephone Company the lecture hall was placed in communication with their service; and Mr. D'Oyley Carte having kindly allowed his stage telephones to be employed, the audience were enabled to hear the opera of the "Gondoliers" performed at the Savoy Theatre. But a more novel and important feature was a line which connected them to the Theatre Royal, Manchester, enabling them to hear the Pantomime which was then in progress.

**Overhead Wires and Snowstorms.**—According to Reuter's telegrams, a snowstorm, accompanied by strong winds, visited New York and its vicinity on Saturday night last. Although the fall of snow only amounted to six inches, the storm in its effect upon telegraph, telephone, and electric-light wires was the most destructive that has occurred since the great blizzard of 1888. New York was practically cut off from telegraphic communication with the rest of the country. The fallen poles and wires crossed the surface of the ground in all directions, and in some cases, where they had fallen across the tracks of the elevated railroad, almost stopped the traffic. The effect of the storm was specially felt by the various exchanges and mercantile houses, the breaking of telephone wires having almost brought business to a standstill In the city the telephone wires suffered most from the storm, the telegraph wires being chiefly underground. The Metropolitan Telephonic Company report that from 2,500 to 3,000 of their wires are broken. The Western Union Telegraph Company are at present unable to form an idea of their losses.

**Electric Lighting Memoranda.**—The following paragraph appears in the "Electric Lighting Memoranda" of the *Journal of Gas Lighting*:—"It was recently remarked in this column that since platinum has been so greatly in demand by electricians, the price of the metal has more than doubled; and something like a famine in regard to it has declared itself. Now it is reported that the same thing is about to happen with gutta-percha, which is growing so scarce that all sorts of inferior substitutes are being sold under the name; and consequently electricians are experiencing the greatest difficulty in keeping up the resistance of their insulated cables to the standard of a few years ago. Meanwhile, the value of copper is falling. These movements are favourable to the low-tension direct-supply companies now purchasing the heavy copper conductors in which so much of their capital is sunk, although the value of the mains already laid is correspondingly depreciated. The alternating current high-potential companies, on the other hand, will be more perplexed than ever if they cannot procure enough good *gutta-percha* to keep their output from leaking out of the mains."

**The Protection of the Electrical Industry in France.**—The proposed list of duties on electrical apparatus entering France, which we published in our issue of December 5, 1890, has not yet been approved of by the Customs Commission. Our Paris correspondent states that he has conversed with a number of people on the subject of the proposed duties, some of whom were pecuniarily interested in the matter, while others had no direct interest. It was generally admitted that the result of the imposition of such heavy duties would be to favour the French electrical industry, since even if the countries chiefly

Digitized by Google

affected indulged in reprisals they would be unable to effectually retaliate, the French exports of electrical apparatus being comparatively small. On the other it was pointed out that foreign competition would probably only become more direct, since several English, American, and German houses have announced their intention of establishing factories in France the moment the Bill passes the Chamber. If this is done the condition invariably imposed by the Paris municipality, whenever it grants an electric lighting concession, that all the plant shall be of French make will be complied with.

**A New Form of Meter Regulator.**—I have just been given by the superintendent of an electric light station in my territory a strange instance of the stopping of a meter, and of the explanation of its conduct, says Mr. Alfred Braddell in the *Electrical Engineer* of New York. On going to read the meter (a 20-light instrument) he found that the consumer had placed a mass of small boxes around the meter. As it was desirable not to disturb them, it was agreed that the meter should be allowed to run another month. Upon the expiration of this time, the coast being clear, the meter was examined, and it was found that it had only recorded five hours during the whole two months. A very close inspection was made, and it was discovered that a spider had spun its web around the fans so that they could not rotate under the action of the current. It appeared that the screw which holds the cover to the top of the instrument had not been put in, and, no doubt, the wily spider perceiving that he could secure a warm lodging free of rent, crept in through the opening thus provided, and without malice aforethought or otherwise, there took up his abode. The moral is that station superintendents as well as flies should beware of spiders.

**Electricity in Mines.**—At a meeting of the Federated Institution of Mining, held at Newcastle last week, a long discussion took place on Mr. Albion T. Snell's Paper on "The Distribution of Electrical Energy over Extended Areas in Mines," which was read at the Sheffield meeting in January, 1890 (see *The Electrician*, Vol. XXIV., p. 294). Messrs. Sydney F. Walker, A. L. Steavenson, M. H. Mills, Brown and Arnold Lupton took part in the discussion, the chief points raised being whether such an E.M.F. as 500 volts was either safe or advantageous in mines, whether electrical transmission gave greater useful effect than wire ropes or compressed air, and, finally, whether the using of continuous-current transformers would not nullify any advantages to be gained by use of high potential in the mains. Mr. Brown, of St. John's Colliery, Normanton, stated that they had been using an E.M.F. of 700 volts for three years without any accident, and that the efficiency of their electrical plant was far higher than the old system of compressed air. Mr. Snell pointed out that he only advocated the use of transformers in isolated instances, where small motors were to be put to work at inaccessible points, and where the advantage of using such motors would be so great as to entirely override any question of efficiency.

**The Junior Engineering Society.**—The sixth annual dinner of this society was held at the Holborn Restaurant on Friday last, when about sixty members and visitors assembled. The President, Prof. Silvanus Thompson, made some remarks upon the connection between engineering and science, and alluded to the ingenious inventions of those who had never enjoyed a regular mechanical training. In the absence of Sir John Fowler, Mr. F. E. Cooper responded for the Past Presidents and Vice-Presidents, and referred to Sir John Fowler's warm sympathy with the younger members of the engineering profession. Speaking of the visit of the members of the Junior Engineering Society to the Forth Bridge during the highly successful excursion of last summer, he remarked that from none of the numerous parties whom he had conducted over the works had he ever received such intelligent questions, or had so much pleasure in answering as on that occasion. Mr. J. C. Fell, replying for the honorary members in the absence of Mr. J. Macfarlane Gray, alluded to the great value of the society in promoting fellowship among its members, he congratulated them on their flourishing condition, and the thorough way in which they conducted their visits to engineering works and factories, and on the great increase of their numbers. Mr. A. J. Walter, in proposing the toast of the Junior Engineering Society, endorsed the great importance of the facilities which such a body offers for mutual intercourse and friendship, and the value of such *camaraderie* to those who were making a start in their profession, and the excellent opportunity afforded by their meetings for practice in public speaking and discussion.

**The Variations of the E.M.F. of Primary Cells.**—At a recent meeting of the Royal Society, a Paper by Messrs. G. J. Burch and V. H. Veley was read on "The Variations of Electromotive Force of Cells consisting of certain Metals, Platinum, and Nitric Acid." The following conclusions were drawn from the results of the experiments:—(1.) When the metals, copper, silver, bismuth, and mercury, are introduced into purified nitric acid of different degrees of concentration, and a couple made of platinum, the electromotive force of such a cell increases considerably from an initial value until it reaches a constant and—in most cases—a maximum value. The rise of electromotive force is attributed to the production of nitrous acid by the decomposition of the nitric acid, and the final value is considered to be due to the former acid only, while the initial value is due for the most part to the latter acid, though it is affected to a remarkable degree by the amount of impurity of nitrous acid, either initially present or produced by minute and unavoidable uncleanliness of the metallic strip and the containing vessel. (2.) If nitrous acid has been previously added to the nitric acid, then the maximum electromotive force is reached at once. (3.) If the conditions—namely, increase of temperature, of impurity, and of concentration of acid—are such as would favour a more rapid solution of the metal, and consequently a more rapid production of nitrous acid, then the rise of electromotive force is concomitantly more rapid. (4.) Conversely, if the conditions are unfavourable to the production of nitrous acid, the rise of electromotive force is less rapid. (5.) If any substance, such as urea, be added, which would tend to destroy the nitrous acid as fast as it may be formed, then the rise of electromotive force is extremely slow, being dependent upon the number of molecular impacts of the nitrous acid upon the surface of the metal.

**Metallo Chromes.**—The production of Nobili's rings, says Mr. George Hopkins in the *Scientific American*, is a very simple and pleasing electro-chemical experiment which may be readily tried by any one having one or two batteries or a small dynamo. To produce the rings, all that is required is a Bunsen or Grenet battery in good order, a strong solution of acetate of lead (sugar of lead), and a steel or nickel-plated brass plate. The lead solution is placed in a saucer, the steel or nickelled plate is placed at the bottom and connected by a wire with the zinc pole of the battery, and the end of the wire, which is connected with the carbon pole of the battery, is held near the steel plate without touching it. In a very short time a spot of colour will appear on the plate, and in a minute or so the spot will spread rapidly and form concentric rings of prismatic colours. A few trials will enable the operator to determine the time required for the production of the best effects. When the operation has proceeded far enough, the plate is removed from the solution, washed in clean water and dried. The beautiful colour effect is due to the decomposition of the light, by the exceedingly thin film of peroxide of lead deposited on the surface of the plate. It is quite permanent, and serves to protect the surface of the plate from oxidation. To secure the best results, the plate should be highly polished and the lead solution should be filtered. Since the discovery of this effect in 1826 by Nobili many modifications of the process have been devised, and some commercial applications have been made. It has been used to some extent in the ornamentation of small objects, such as buttons, articles of jewellery, &c., imparting to them an iridescence which cannot be imitated by any artificial colouring. Becquerel suggested a solution for this purpose, the formula of which is as follows: "Dissolve 200 grammes of caustic potash in 2 quarts of distilled water, add 150 grammes of litharge, boil the mixture for a half hour, and allow it to settle. Then pour off the clear liquor and dilute with its own bulk of water." This solution is adapted to other metals than those above mentioned, but the acetate of lead solution yields very satisfactory results and is sufficient for experimental demonstration.

## ELECTRO-MAGNETIC THEORY.--III.

BY OLIVER HEAVISIDE.

*(Continued from page 331.)*

§ 14. It will have been observed that I have said next to nothing upon the study of pure mathematics; this is a matter with which we are not concerned. But that I have somewhat dilated (and I do not think needlessly) upon the advantages attending the use of mathematical methods by the materialist to assist him in his study of the laws governing the material universe, by the proper co-ordination of known and the discovery of unknown (but not unknowable) phenomena.

It was discovered by mathematical reasoning that when an electric current is started in a wire, it begins entirely upon its skin, in fact upon the outside of its skin; and that, in consequence, sufficiently rapidly impressed fluctuations of the current keep to the skin of the wire, and do not sensibly penetrate to its interior.

Now very few (if any) unmathematical electricians can understand this fact; many of them neither understand it nor believe it. Even many who do believe it do so, I believe, simply because they are told so, and not because they can in the least feel positive about its truth of their own knowledge. As an eminent practician remarked, after prolonged scepticism, "When Sir W. Thomson says so, who can doubt it?" What a world of worldly wisdom lay in that remark!

Now I *do* admire this characteristically stubborn English way of being determined not to be imposed upon by any absurd theory that goes against all one's most cherished convictions, and which cannot be properly understood without mathematics. For without the mathematics, and with only the sure knowledge of Ohm's law and the old-fashioned notions concerning the function of a conducting wire to guide one, no one would think of such a theory. It is quite preposterous from this point of view. Nevertheless, it is true; and the view was not put forward as a hypothesis, but as a plain matter of fact.

The case in question is one in which we can be very sure of all the fundamental data of any importance, and the laws concerned. We can, for instance, by straightforward experiment, especially with properly constructed induction balances admitting of exact interpretation of results, readily satisfy ourselves that a high degree of accuracy must obtain not merely for Ohm's law, but also for Faraday's law of E.M.F. in circuits, and even in iron for Poisson's law of induced magnetisation, within certain limits. We have, therefore, all the conditions wanting for the successful application of mathematical reasoning of a precise character, and justification for the confidence that mathematicians can feel in the results theoretically deduced in a legitimate manner, however difficult it may be to give an easily intelligible account of their meaning to the unmathematical.

This, however, I will say for the sceptic who has the courage of his convictions, and writes openly against what is, to him, pure nonsense. He is doing, in his way, good service in the cause of truth and the advancement of scientific knowledge, by stimulating interest in the subject and causing people to inquire and read and think about these things, and form their own judgment if possible, and modify their old views if they should be found wanting. Nothing is more useful than open and free criticism, and the truly earnest and disinterested student of science always welcomes it.

§ 15. The following may assist the unmathematical reader to an understanding of the subject. It is not demonstrative, of course, but is merely descriptive. If, however, it be translated into mathematical language and properly worked out, it will be found to be demonstrative, and to lead to a complete theory of the functions of wires in general.

Start with a very long solenoid of fine wire in circuit with a source of electrical energy. Let the material inside the solenoid be merely air, that is to say, ether and air. If we examine the nature of the fluctuations of current in the coil in relation to the fluctuations of impressed force on it, we find that the current in the coil behaves as if it were a material fluid possessing inertia and moving against resistance. The fanatics of Ohm's law do not usually take into account the inertia. It is as if the current in the coil could not move without simultaneously setting into rotation a rigid material core filling the solenoid, and free to rotate on its axis.

If we take the air out of the solenoid and substitute any other non-conducting material for a core the same thing happens; only the inertia varies with the material, according to its magnetic inductivity.

But if we use a conducting core we get new phenomena, for we find that there is no longer a definite resistance and a definite inertia. There is now frictional resistance in the core, and this increases the effective resistance of the coil. At the same time the inertia is reduced.

On examining the theory of the matter (on the basis of Ohm's law and Faraday's law applied to the conducting core) we find that we can now account for things (in our analogy) by supposing that the rigid solid core first used is replaced by a viscous fluid core, like treacle. On starting a current in the coil it cannot now turn the core round bodily at once, but only its external portion. In time, however, if the source of current be steadily operating, the motion will penetrate throughout the viscous core, which will finally move as the former rigid core did. If, however, the current in the coil fluctuate in strength very rapidly, the corresponding fluctuations of motion in the core will be practically confined to its skin. The effective inertia is reduced because the core does not move as a rigid body; the effective resistance is increased by the viscosity generating heat.

Now, returning to the solenoid, we have perfect symmetry with respect to its axis, since the core is supposed to be exceedingly long, and uniformly lapped with wire. The situation of the source of energy, as regards the core itself, is plainly on its boundary, where the coil is placed; and it is therefore a matter of common-sense that in the communication of energy to the core either when the current is steady or when it varies, the transfer of energy takes place transversely, that is, from the boundary to the axis, in planes perpendicular to the axis, and therefore perpendicular to the current in the core itself. This is confirmed by the electro-magnetic equations.

But the electro-magnetic equations go further than this, and assert that the transference of energy in any isotropic electrical conductor always takes place across the lines of conduction current, and not merely in the case of a core uniformly lapped with wire, where it is nearly self-evident that it must be so. This is a very important result, being the post-finger pointing to a clear understanding of electro-magnetism. Passing to the case of a very long straight round wire supporting an electric current, we are bound to conclude that the transference of energy takes place transversely, not longitudinally: that is, across the wire instead of along it. The source of energy must, therefore, first supply the dielectric surrounding the wire before the substance of the wire itself can be influenced; that is, the dielectric must be the real primary agent in the electromagnetic phenomena connected with the electric current in the wire.

Beyond this transverse transference of energy, there does not, however, at first sight, appear to be much analogy between the case of the solenoid with a core and the straight wire in a dielectric. The source of energy in one case is virtually brought right up to the surface of the core in a uniform manner. But in the other case the source of energy—the battery, for instance—may be miles away at one end of the wire, and there is no immediately obvious uniform application of the source to the skin of the wire. But observe that in the former case the magnetic force is axial, and the electric current circular, whilst in the latter case the electric current (in the straight wire) is axial and the magnetic force circular. Now an examination of the electro-magnetic equations shows that the conditions of propagation of axial magnetic force and circular current are the same as those for axial current and circular magnetic force. We therefore further conclude that (with the exchanges made) the phenomena concerned in the core of the solenoid and in the long straight wire are of the same character.

Furthermore, if we go into detail, and consider the influence of the surroundings of the wire (which go to determine the value of the inductance of the circuit) we shall find that not only is the character of the phenomena the same, but that they

Digitized by Google

may be made similar in detail (so as to be represented by similar curves, for example).

The source of energy, therefore, is virtually transferred instantly from its real place to the whole skin of the wire over which it is uniformly spread, just as in the case of the conducting core within a solenoid.

§ 16. So far we can go by Ohm's law and Faraday's law of E.M.F., and, if need be, Poisson's law of induced magnetisation (or its modern equivalent practically). But it is quite impossible to stop here. Even if we had no knowledge of electrostatics and of the properties of condensers, we should, by the above course of inquiry be irresistibly led to a theory of transmission of electrical disturbances through a medium surrounding the wire, instead of through the wire. Maxwell's theory of dielectric displacement furnishes what is wanted to explain results which are in some respects rather unintelligible when deduced in the above manner without reference to electrostatic phenomena.

We learn from it that the battery or other source of energy acts upon the dielectric primarily, producing electric displacement and magnetic induction; that disturbances are propagated through the dielectric at the speed of light; that the manner of propagation is similar to that of displacements and motions in an incompressible elastic solid; that electrical conductors act, as regards the internal propagation, not as conductors but rather as obstructors, though they act as conductors in another sense, by guiding the electro-magnetic waves along definite paths in space, instead of allowing them to be immediately spread away to nothing by spherical enlargement at the speed of light; that when we deal with steady states, or only slowly varying states, involving immensely great wave length in the dielectric, the resulting magnetic phenomena are just such as would arise were the speed of propagation infinitely great instead of being finite; that if we make our oscillations faster, we shall begin to get signs of propagation in the manner of waves along wires, with, however, great distortion and attenuation by the resistance of the wires; that if we make them much faster we shall obtain a comparatively undistorted transmission of waves (as in long-distance telephony over copper wires of low resistance); and that if we make our oscillations very fast indeed, we shall have practically mere skin conduction of the waves along the wires at the speed of light, as in some of Lodge's lightning-conductor experiments, and more perfectly with Hertzian waves).

Now all these things have been worked out theoretically, and, as is now well known, most of them have been proved experimentally; and yet I hear someone say that Hertz's experiments don't prove anything in particular!

Lastly, from millions of vibrations per second, proceed to billions, and we come to light (and heat) radiation, which are, in Maxwell's theory, identified with electromagnetic disturbances. The great gap between Hertzian waves and waves of light has not yet been bridged, but I do not doubt that it will be done by the discovery of improved methods of generating and observing very short waves.

## INSTITUTION OF ELECTRICAL ENGINEERS.

PRESIDENTIAL ADDRESS OF PROF. WILLIAM CROOKES, F.R.S.

### Electricity in Transitu: from Plenum to Vacuum.

(*Concluded from p. 360.*)

*The Resistance of High Vacua.*

I must only lightly touch this phenomenon to-night; it is a subject of deep interest, and one to which I have lately devoted much time. Shortly I hope to publish a full account of results recently obtained.

The passage of an induction current at a high vacuum through a tube depends much upon the material of the tube or the substance enclosed within it. Given the same degree of exhaustion, and the same distance between the terminals inside the tube, the E.M.F. necessary to force the current through may vary from 3,000 volts to 20,000 volts, according to the particular material used.

Here is a very striking example that will serve to illustrate this phenomenon. Fig. 27 is a double tube joined by a narrow open channel and therefore in the same state of exhaustion throughout (P = 0·02 mm. or 26 M). Each tube is furnished with a pair of poles, A, B, and A′, B′. One tube contains the phosphorescent earth yttria, the other contains finely divided carbon. I first connect the yttria tube, C, to the coil, and place in parallel circuit with it a spark gauge. To begin with, this gauge is set to a gap of 1 mm. (An E.M.F. of 920 volts is necessary to strike across 1 mm. of air; therefore the difference of potential at the terminals inside the yttria tube is 920 volts, and this you perceive is not sufficient to force the current through the tube.) I now gradually open the gauge until the potential of the inner terminals has risen to a point high enough to allow the spark to pass through the tube, making the yttria phosphorescent.

The gap is at 7 mm. equal to an E.M.F. of 6,440 volts. I next attach the coil wires to the tube D containing the carbon, and the exhaustion in the tubes being the same as before, I repeat the experiment; you now see that the gap has to be opened to 30 mm., equivalent to an E.M.F. of 27,600 volts, before the current will pass through the tube. The fact of whether the vacuum tube contains yttria or carbon makes a difference of 21,160 volts in the E.M.F. required to cause a discharge between the terminals.

One other experiment I would like to show in further illustration of this resistance. The idea suggested itself that possibly differences in the material or conductivity of the particular bulbs might influence the results you have just seen.

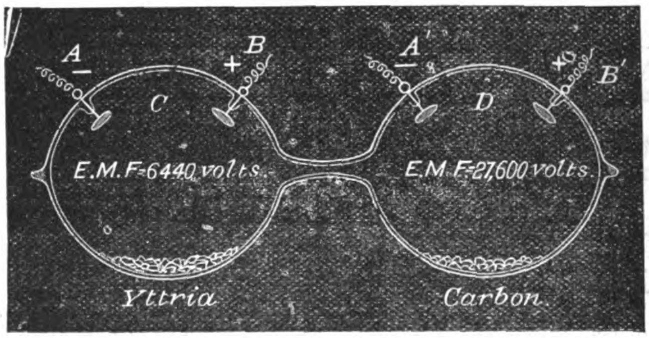

Fig. 27.—Pressure = ·02mm = ·25 M.

Here (Fig. 28) is a long cylindrical tube of phosphorescent Bohemian glass containing a pair of terminals, A, B; it also contains a shorter cylinder of glass, C, C, brightly silvered inside. The internal pressure is 0·00068 mm., or 0·9 M. The silver cylinder is now at one end of the tube out of the way of the terminals, which, therefore, have phosphorescent glass around them. I turn on the coil and find that the E.M.F. necessary to force the current through, now that the terminals are in a phosphorescent chamber, is 1,380 volts. I slide the cylinder down to the end of the tube so as to enclose the terminals in a metallic silver chamber, and you see the E.M.F. necessary to pass the current rises to 6,440 volts. Metallic silver does not phosphoresce, whilst Bohemian glass phosphoresces very well. It appears that the greater the phosphorescing power of the substance surrounding the poles so much the easier does the induction spark pass. Surround the poles with Bohemian glass or yttria—two phosphorescent non-conductors of electricity—and the induction spark passes easily; immediately I surround the terminals with a non-phosphorescent conductor the current refuses to pass.

*What Occasions Phosphorescence?*

I should like to interest you in a question that has exercised my mind for some time past. What is it that occasions the phosphorescence of yttria and other bodies *in vacuo* under molecular bombardment?

So far I have found this phosphorescence to be an attribute of non-conductors only. We know that in the act of phosphoresence the molecules of yttria are in a state of intense vibration. Each molecule may be viewed as the radiating

Digitized by Google

centre of the entire bundle of rays, which, when decomposed by the prism, displays a discontinuous spectrum. We may also suppose that the residual atoms of gas charged with negative electricity give off their electricity on coming in collision with a phosphorescent body and on their return take up a fresh charge.

*The Electrolysis Hypothesis.*

There is a certain amount of evidence in favour of an electrolytic hypothesis of the passage of electricity through rarefied gases. This has been ably advocated by Prof. Schuster in the Bakerian Lecture before the Royal Society, March 20, 1890.*

A molecule of hydrogen gas, for instance, may be made up of one group of atoms of hydrogen having an equivalent of negative electricity inherent in it, and one group of atoms having an equivalent of positive electricity bound up with it. These atoms are also charged with *additional* equivalents of positive or negative electricity, which they carry about as a ship carries its cargo. We are not concerned with the inherent electricity—of which we are ignorant—but with the extra or "cargo" charge. Let us imagine a molecule of hydrogen near the face of the negative pole in a vacuum tube. I turn on the current, and the atoms of the hydrogen molecule are dragged apart. The positive atom is attracted to the negative pole, where the violence of impact, or the discharge of electricity, renders it apparent with evolution of light. The internal luminous layer, which is closely adjacent to the negative electrode, is due, therefore, to the positive atoms rushing to the negative pole, and not like the glow round the edge of the dark space, to the negative atoms projected from it. The negative atom, on the other hand, is driven violently from the negative pole, in virtue of the mutual repulsion existing between any two bodies similarly electrified, with a velocity varying with the intensity of the electrification and the degree of the vacuum; the more perfect the vacuum the greater the velocity, the atoms flying outwards in straight lines until they meet with an obstacle. Such an obstacle may be a procession of positively charged atoms from the positive pole; in this case the two kinds of atoms mutually discharge each other's cargoes with a display of light. This phenomenon occurs at the margin of the dark space when the vacuum is only moderate. Or the obstacle may be produced by the vacuum being so high that the atoms of gas present are too few to form a continuous procession. (*Why* a high vacuum should be non-conductive does not clearly appear, but the fact itself is beyond doubt; it is probably connected with the inability of electrified atoms to leave the poles.) Or again, the obstacle may be a phosphorescent body like yttria. In this case the negatively charged atoms deliver up their charge of electricity to the yttria, which is so constituted—perhaps after the manner of a Hertz resonator—that its atoms charge and discharge, vibrating about 550 billion times in a second, and producing waves in the ether of the length, approximately, of 5·74 ten-millionths of a millimetre, and occasioning in the eye the effect of citron light.

We are not under the necessity of supposing that this number of hydrogen atoms are driven against the yttria in the second, although even at a high vacuum there are quite enough atoms left in the bulb to keep up such a supply. All that is needed is that a succession of shocks, not necessarily rhythmical, may strike the yttria at frequencies which will set up such a number of vibrations, just as a series of slow impacts on a gong causes it to emit sound waves of much greater frequency.

In a low vacuum only very few atoms can run the gauntlet among the crowd of inrushing atoms, and those few which succeed in reaching the yttria arrive with much reduced velocity, and so faint is the phosphorescence they set up that it is completely obscured* by the brighter phosphorescence of the residual gas. As the vacuum becomes higher, more and more atoms find their way across, and their speed being at the same time accelerated, the phosphorescence becomes intensified.

At a good vacuum most of the atoms hit the yttria, their velocity is increased, and the rhythmical excitation reaches its maximum.

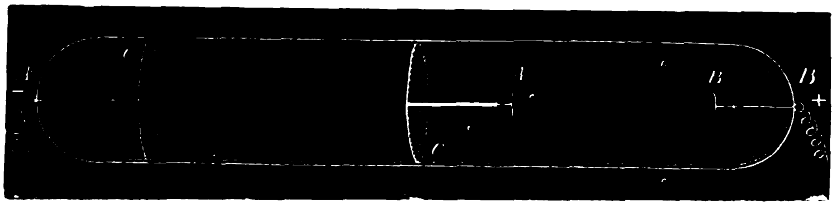

Fig. 28.—Pressure ·00068mm. = ·9 M.
Silvered Cylinders away from Poles. E.M.F. = 1380 volts.
Silvered Cylinders round Poles. E.M.F. = 6440 volts.

*The Dark Space in Mercury Vapour.*

In applying the electrolytic hypothesis, I have used for illustration's sake the gaseous residue of hydrogen, which is known as a diatomic gas. I have found, however, the phenomena of the dark space, &c., to occur in the vapour of mercury, which is a monatomic gas. This important result induced me to patiently investigate this subject, and the result of one experiment is before you (Fig. 29). The tube is furnished with aluminium terminals, and is so arranged that the induction spark can be kept passing during exhaustion to drive off occluded gases. When at the highest attainable vacuum, the tube is filled with pure mercury by simply raising a reservoir. On applying heat the entire contents of the tube are boiled away and pass down the fall tubes of the pump, exhaustion going on at the same time. When the whole of the mercury has thus been boiled away *in vacuo*, except a little condensed at the upper part of the tube, the results on passing the spark are as follows:—When the tube is cold the induction current refuses to pass; on gently

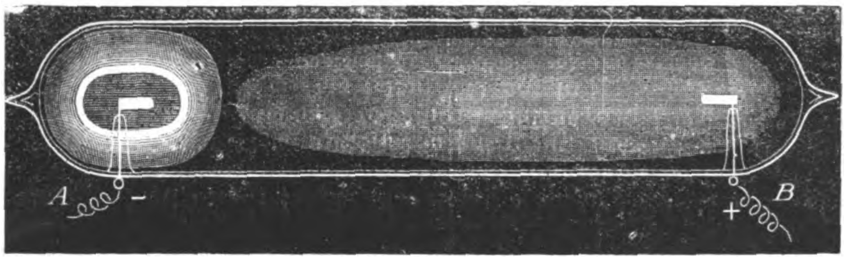

Fig. 29.

heating with a gas-burner the current passes and the dark space is distinctly visible. Continuing the heat so as to volatilise the drops of mercury condensed on the sides, the whole tube becomes filled with a green phosphorescent light, the dark space gets smaller and smaller, and ultimately the negative pole becomes covered with a luminous glow. On allowing the tube to cool the same phenomena ensue in inverse order. The luminous halo expands, showing the dark space between it and the pole, and this dark space gradually grows larger as the tube becomes cooler. The mercury again condenses on the side of the tube, the green phosphorescence grows paler and paler, until at last the induction spark from the large coil refuses to pass.

therefore say that the atoms in a molecule of free hydrogen act in chemistry as two separate groups, each of a minimum relative weight of I, whilst those in a molecule of free mercury act as one undivided group of the relative weight 200. But to what number of atoms the I and 200 correspond respectively no chemist knows.

To show how intimately chemistry and electricity interlock, I may here remark that one of the latest theories in chemistry renders such a division of the molecule into groups of electro-positive and electro-negative atoms necessary for a consistent explanation of the genesis of the elements. This is so important that I may be excused for digressing a little into this development of theoretical chemistry.

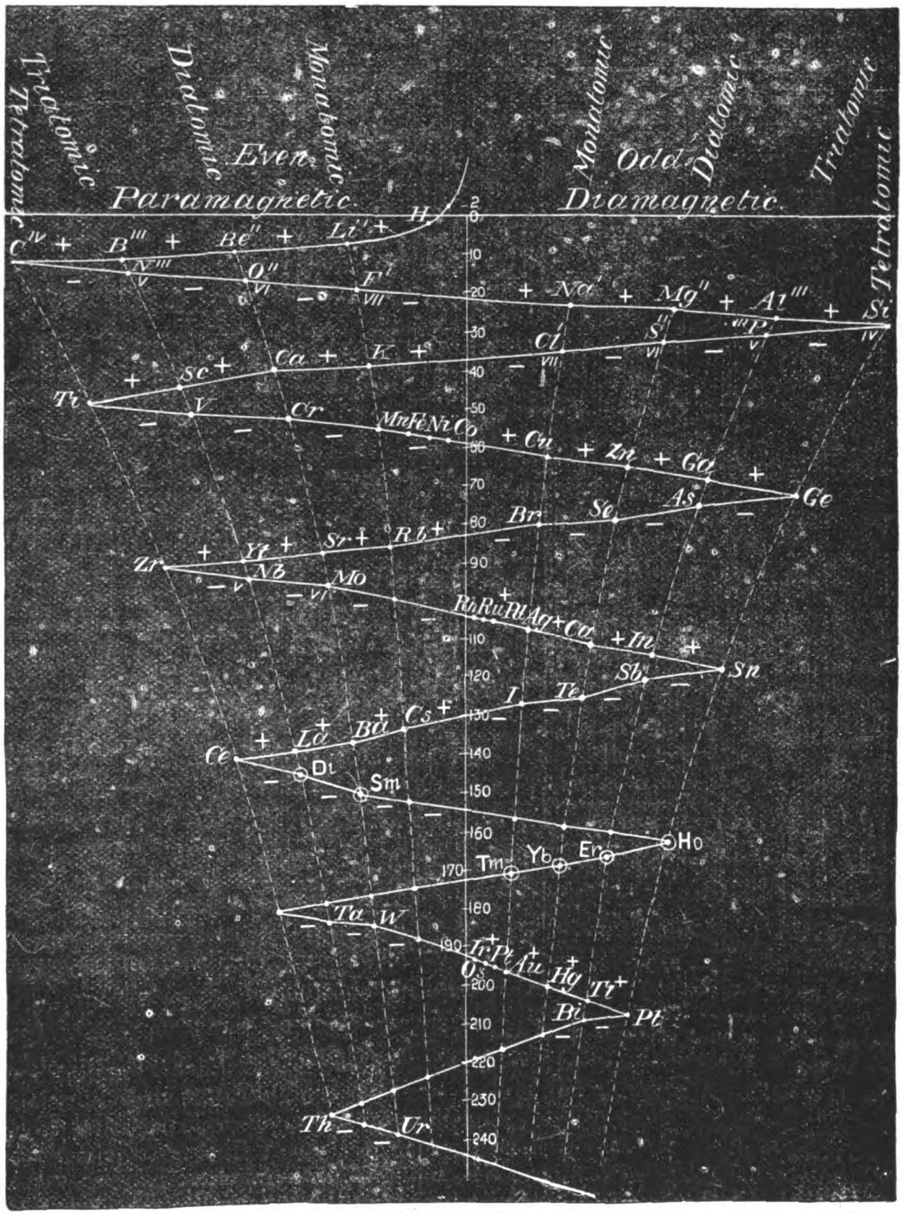

FIG. 30.—Mendeljeef's diagram of the periodic law of elements.

At first sight this result appears fatal to the electrolytic hypothesis, for if the molecule of mercury contains only one atom, how can we talk of its separation into positive and negative atoms by the electric stress? It must be remembered, however, that we are as yet ignorant of the absolute mass of the atom of any element. All that can be said is that a molecule of free hydrogen becomes halved in combining chemically with certain other elements, whilst a molecule of free mercury does not suffer division on yielding any known compound of mercury; the physical atoms in the one behave as two separate groups, and those in the other as one undivided group. It has been agreed by chemists, for simplicity's sake and for facilitating chemical calculations, to reduce the units to the lowest term, consistent with the avoidance of fractions; we

*Genesis of the Elements.*

It is now generally acknowledged that there are several ranks in the elemental hierarchy, and that besides the well-defined groups of chemical elements, there are underlying sub-groups. To these sub-groups has been given the name of meta-elements. The original genesis of atoms assumes the action of two forms of energy working in time and space —one operating uniformly in accordance with a continuous fall of temperature, and the other having periodic cycles of ebb and swell, and intimately connected with the energy of electricity (Fig. 30). The centre of this creative force in its journey through space scattered seeds or sub-atoms that ultimately coalesced into the groupings known as chemical elements. The law which governs the motions of multitudes of men and

Digitized by Google

women in a busy thoroughfare I have applied to the atoms of gas in a vacuum tube. At this genetic stage the new-born particles vibrating in all directions and with all velocities, the faster-moving ones would still overtake the laggards, the slower would obstruct the quicker, and we should have groups formed in different parts of space. The constituents of each group, whose form of energy governing atomic weight was not in accord with the mean rate of the bulk of the components of that group, would work to the outside and be thrown off to find other groups with which they were more in harmony. In time a condition of stability would be established, and we should have our present series of chemical elements, each with a definite atomic weight—definite on account of its being the average weight of an enormous number of sub-atoms or meta-elements, each very near to the mean. The atomic weight of mercury, for instance, is called 200, but the atom of mercury, as we know it, is assumed to be made up of an enormous number of sub atoms, each of which may vary slightly round the mean number 200 as a centre.

We are sometimes asked why, if the elements have been evolved, we never see one of them transformed, or in process of transformation, into another? The question is as futile as the cavil that in the organic world we never see a horse metamorphosed into a cow. Before copper, *e g.*, can be transmuted into gold it would have to be carried back to a simpler and more primitive state of matter, and then, so to speak, shunted on the track which leads to gold.

This atomic scheme postulates a to and fro motion of a form of energy governing the electrical state of the atom. It is found that those elements generated as they approach the central position are electro-positive, and those on the retreat from this position are electro negative. Moreover the degree of positiveness or negativeness depends on the distance of the element from the central line: hence calling the atom in the mean position electrically neutral, those sub-atoms which are on one side of the mean will be charged with positive electricity, and those on the other side of the mean position will be charged with negative electricity, the whole atom being neutral.

This is not a mere hypothesis, but may take the rank of a theory. It has been experimentally verified as far as possible with so baffling an enigma. Long-continued research in the laboratory has shown that in matter which has responded to every test of an element, there are minute shades of difference which have admitted of selection and resolution into meta-elements, having exactly the properties required by theory. The earth yttria, which has been of such value in these electrical researches as a test of negatively excited atoms, is of no less interest in chemistry, having been the first body in which the existence of this sub-group of meta-elements was demonstrated.

*Conclusion.*

I frankly admit I have by no means exhausted the subject which daily and nightly fills my thoughts. I have ardently sought for facts on which to base my theory. I have struggled with problems which must be conquered before we can arrive at exact conclusions—conclusions which, so far as inorganic nature is concerned, can only be reached by the harmonious interfusion—not confusion—of our present twin sciences, electricity and chemistry. Of this interfusion I have just endeavoured to give you a foretaste. In elaborating the higher physics, the study of electrical phenomena must take a large, perhaps the largest, share. We have invaded regions once unknown, but a formidable amount of hard work remains to be completed. As we proceed we may look to electricity not only to aid, as it already does, our sense of hearing, but to sharpen and develop other powers of perception. Science has emerged from its childish days. It has shed many delusions and impostures. It has discarded magic, alchemy, and astrology. And certain pseudo-applications of electricity, with which the present institution is little concerned, in their turn will pass into oblivion. There is no occasion to be disheartened at the apparent slow pace of elemental discovery. The desponding declare that if Roger Bacon could re-visit "the glimpses of the moon" he would shake his head to think we have got no further, that we are still in a haze as to the evolution of atoms. As for myself I hold the firm conviction that unflagging research will be rewarded by an insight into natural mysteries such as now can scarcely be conceived. Difficulties, said a keen old statesman, are things to be overcome, and to my thinking science should disdain the notion of finality. There is no stopping half-way, and we are resistlessly driven to ceaseless inquiry by the spirit "that impels all thinking things, all objects of all thought, and rolls through all things."

## OVERHEAD WIRES IN LONDON.

As considerable misapprehension existed last year as to what was and what was not contemplated by the London County Council in their Bill of that date dealing with overhead wires in the metropolis, we print this week some of the more important clauses of "The London Overhead Wires Act, 1891." The Bill is an eminently reasonable one; interference with property rights is carefully guarded against, and the intrusion of the "uniformed inspector" is made as gentle an attack upon the Englishman's castle as can well be if overhead wires are to be submitted to any supervision at all.

Clauses 1 and 2 relate to the title of the Bill and to definitions of expressions used therein.

**Removal of wires into subway.**

3. Where the Council have a subway in any street it shall be lawful for the Council at any time to require the Company by notice in writing to remove into such subway any then existing wire of the Company over the street which can conveniently be placed in such subway. If any question shall arise between the Council and the Company as to whether such subway is, in fact, convenient for the reception of such wire, or whether, having regard to the purposes for which such wire is used, it can, under the circumstances, be conveniently placed in such subway, the matter shall be settled by an arbitrator.

**Charge for use of subway.**

4. It shall be lawful for the Council to make on the Company using any subway of the Council a charge by way of rent for such use and contribution towards the costs of maintenance and supervision according to a scale to be determined by such bye-laws as hereafter provided.

**Maintenance of wires in subway.**

5. Every wire placed in a subway shall be maintained and kept in proper condition and repair by and at the expense of the Company to whom it *belongs*, under the direction and supervision of the officer to be appointed for that purpose by the Council. If the Company fail at any time to keep any such wire in proper condition and repair, it shall be lawful for the Council to place the same in proper condition and repair and to execute any works which may be necessary for that purpose, and the amount of any costs and expenses to which the Council may be put in connection with any such work shall be repaid on demand to the Council by the Company to whom the wires belongs, and in default of such payment may be recovered by the Council in a summary way. Every subway shall be maintained and kept in proper condition and repair by the Council, with efficient means of ventilation, and free from water and other obstructions in the way of the Company.

**New overhead wires not to be placed except in accordance with bye-laws.**

6. From and after the passing of this Act the Company shall, within one month after they shall have placed any wire overhead, give notice in writing to the Council and the Local Authority, specifying the locality and position in which the wire has been placed; and after bye-laws in relation to wires shall have been made under powers of this Act it shall not be lawful to place any wire overhead otherwise than subject to and in accordance with such bye-laws.

Clause 7 deals with the question of connections of wires in subways with other wires outside.

**Charges for Supervision of Wires.**

8. The Local Authority may charge every Company and person owning any wire placed or retained overhead after the passing of this Act such reasonable fees in respect of the identification and such reasonable annual charges in respect of supervision of wires as shall be fixed by the bye-laws hereinafter provided.

**Rights over private property not to be acquired except by agreement.**

9. The Company shall not otherwise than by agreement with the owner of and persons interested therein by carrying a wire over any land or building, or supporting such wire thereon or attaching the same thereto, acquire any right which shall in any way interfere with any right of such owner or other person, and if at any time by reason of any alteration, rebuilding, or otherwise, it becomes necessary for any such owner or person to require the Company to alter or remove any such wire the Company shall alter or remove the same accordingly on being required so to do by notice in writing by such owner or person. And in the event of the Company

Digitized by Google

refusing or neglecting for the space of one month after such requisition to alter or remove the same, it shall be lawful for any inspector, officer, or workman duly appointed by the Council to remove or alter the same, and to enter upon the land or building for that purpose, and the costs and expenses of and incidental to such removal shall be repaid by the Company to the Council on demand, and in default of payment may be recovered in a summary way. As regards the City of London this section shall be read and have effect as if the Commissioners of Sewers were named therein instead of the Council.

Clause 10 details the matters on which bye-laws may be made, such as the identification of overhead wires; the regulation of wires; the strength of the materials to be employed in placing, maintaining, and supporting wires; the removal of wires erected or placed otherwise than in accordance with such bye-laws and of disused wires; the determination of a scale of fees and charges to be paid by way of rent for the use of any subway, and in respect of the identification and supervision of wires, and the terms and conditions to which the Company and persons employed by them and using the subways shall be subject.

No bye-law is to have any effect until approved by the Board of Trade, who may also exempt any then existing wire from the operation of any bye-law for such period as they think proper not exceeding five years from the confirmation thereof.

**Enforcement of bye-laws by Local Authority.** 11. Bye-laws under this Act shall, subject to the provisions of this Act be enforced and administered by the Local Authority except in so far as they shall relate to any subway of the Council, in which case they shall be enforced and administered by the Council.

Clause 12 provides for uniformity in enforcement of bye-laws.

**Inspectors of overhead wires.** 13—1. It shall be lawful for the Council or the Local Authority, as the case may be, to appoint and employ an inspector or inspectors of wires and such other officers and workmen as they may find requisite for the purposes of this Act.

2. *Any such inspector being in uniform, and duly authorised in writing by the Council or Local Authority in that behalf, may, after notice previously given, enter at a reasonable time to be named by the occupier, or if there be no occupier by the owner, on any lands, houses, and premises for the purpose of inspecting any wire supported thereon or attached thereto, or of removing or altering such wire under the powers of this Act; and if the occupier fails to name a time for such entry within four days after request, nor in any case of emergency, such inspector may enter without further notice.*

**Removal of existing overhead wires.** 14. If at any time, on the report of any of their inspectors, it shall appear to the Local Authority that any wire is in such a condition that danger to the public using the streets may be apprehended, the Local Authority may serve notice in writing on the Company, requiring them to remove, renew, or alter the same, and to place such wire in such position as the Local Authority may reasonably determine; and in the event of such requisition not being complied with within such time as shall be therein specified, it shall be lawful for the Local Authority to apply to a Court of Summary Jurisdiction to issue a summons calling on the Company to show cause why the wire should not be dealt with in accordance with such requisition, and such Court may make an order authorising the Local Authority or any of their inspectors or officers, to remove or alter any such wire, and to charge the expenses of such removal or alteration on the Company, to whom the wire belongs, as may be prescribed in such order. And such expenses may be recovered under the provisions of the Summary Jurisdiction Acts. Provided that the Local Authority may at any time, after bye-laws shall have been made under the provisions of this Act, proceed under this section without any such notice or requisition in the case of any wire not being in accordance with such bye-laws, and at any time after such bye-laws are made it shall be lawful for the Council or Local Authority to remove any such wire if they are unable to ascertain the owner thereof.

Clauses 15 to 20 relate to liability for accidents, arbitration, recovery of penalties, &c., &c.

**Wires not to be inconsistent with regulations of Board of Trade.** 21. The Company shall not under the powers of this Act or any bye-law made under this Act be required to place any wire in any manner which shall be inconsistent with any regulation or condition for securing the safety of the public or for the protection of the electric lines and works of the Postmaster-General made, prescribed or imposed by the Board of Trade under the "Electric Lighting Acts 1882 and 1888" or any Provisional Order made under those Acts and confirmed by Parliament.

**Electric currents not to be interfered with.** 22. The Council or Local Authority shall not under the powers of this Act require or permit the Company to place or use any wire in such position or manner as may have the effect of disturbing or interfering by induction or otherwise with the action of any electric currents from time to time used or intended to be used for the purpose of telegraphic, telephonic, or electric signalling communication. But the Council may alter or rearrange any pipes or wires in any subway in order to prevent any such disturbance or interference by induction or otherwise as aforesaid, and the cost of such alteration or rearrangement shall be defrayed or repaid to the Council by the Company the introduction of whose wires into such subway shall have led to the alteration or re-arrangement.

**As to authorised electric lighting undertakers and wires.** 23. Nothing in this Act or any bye-law or regulation made in pursuance thereof shall apply or extend to any Undertakers acting under Special Act Provisional Order or licence under "The Electric Lighting Acts 1882 and 1888," or to any wires of such Undertakers, except such bye-laws and regulations as are made in pursuance of this Act with respect to the position and manner in which wires shall be placed in subways; the manner in which any repairs to or alterations in any such wires may be made; the control and regulation of persons resorting to any subway, and all persons fixing or altering any wire therein; and then only if and when such Undertakers desire or are required to lay in any subway any wires under the terms of their Special Act or Provisional Order or licence under the provisions of "The Electric Lighting Acts, 1882 and 1888."

**Not to authorise placing unauthorised wires overhead or in subways.** 24. Nothing in this Act contained shall be deemed to authorise the Council to confer any powers of placing wires for electric lighting purposes overhead on any company, body, or person not authorised to place such wires by a Special Act Provisional Order or licence under the provisions of "The Electric Lighting Acts 1882 and 1888" or empower the Council to require or enable any company, body, or person owning or using overhead wires for electric lighting purposes to place such wires in any subway unless such company, body, or person is authorised to supply electricity by Special Act, Provisional Order, or licence under the provisions of "The Electric Lighting Acts, 1882 and 1888."

The remaining clauses of the Bill, five in number, relate to the exemption of Government and Crown property from powers as to overhead wires, and the saving rights of the Postmaster-General.

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**FRIDAY, January 30th.**

INSTITUTION OF MECHANICAL ENGINEERS.

*7.30 p.m.* Annual General Meeting.

INSTITUTION OF CIVIL ENGINEERS.

*7.30 p.m.* Students' Meeting. Paper to be read: "The Counterbalancing of Locomotive Engines," by EDMUND L. HILL, S.I.C.E.

ELECTRO-HARMONIC SOCIETY.

*8 p.m.* Smoking Concert at St. James' Hall Restaurant.

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse: "The Rejuvenescence of Crystals," by Prof. J. W. JUDD, F.R.S.

**MONDAY, February 2nd.**

ROYAL INSTITUTION.

*5 p.m.* General Monthly Meeting.

SOCIETY OF ENGINEERS.

*7.30 p.m.* Ordinary Meeting. Presentation of Premiums. Presidential Address.

SOCIETY OF ARTS.

*8 p.m.* Cantor Lecture II. 2. "The Construction and Capabilities of Musical Instruments," by A. J. HIPKINS F.S.A.

**TUESDAY, February 3rd.**

ROYAL INSTITUTION.

*3 p.m.* Afternoon Lecture: "The Structure and Functions of the Nervous System," by Prof. VICTOR HORSLEY, F.R.S.

INSTITUTION OF CIVIL ENGINEERS.

*8 p.m.* Ordinary Meeting. Paper to be read with a view to discussion: "Electric Mining Machinery," by LLEWELYN B., and CLAUDE W. ATKINSON, A.M.I.C.E.; also ballot for members, and—at 9 p.m.—Reception by the President and Council.

**WEDNESDAY. February 4th.**

SOCIETY OF ARTS.

*8 p.m.* Ordinary Meeting. "Decimal Coinage, Weights and Measures," by J. EMERSON DOWSON.

**THURSDAY, February 5th.**

INSTITUTION OF CIVIL ENGINEERS.

*2 p.m.* Students' Visit. The Refrigerating Machinery at the Victoria Dock.

**FRIDAY, February 6th.**

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse. "Some Applications of Photography," by Lord RAYLEIGH, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

# The Electrician.

**Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny**
**Editorial, Publishing, and Printing Offices:**
**SALISBURY COURT, FLEET ST., LONDON, E.C.**
*Telephone No. 2714. Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

*All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "THE ELECTRICIAN" Printing and Publishing Company, Limited, and be crossed "Coutts and Co." All other letters to be addressed to the Editor.*

*All letters intended for insertion in "THE ELECTRICIAN," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

*"THE ELECTRICIAN" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

*"THE ELECTRICIAN" is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

*New Volumes of "THE ELECTRICIAN" commence in May and November.*

## SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

| | 3 months. s. d. | 6 months. s. d. | 12 months. s. d. |
|---|---|---|---|
| For the United Kingdom | 5 0 | 10 0 | 19 6 |
| For Foreign Parts and Colonies:— Within Postal Union | 6 6 | 12 6 | 24 0 |
| Aden Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar | 7 6 | 14 6 | 28 0 |

## TO ADVERTISERS.

*"THE ELECTRICIAN" offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

*Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xvii.) are accepted up to 4 p.m. on Thursday.*

## TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

## "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

*Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. The DIRECTORY was established in 1883, and the 1890 Edition consisted of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

*The 1891 Edition is now actively preparing, and Subscription and Advertisement Orders, New Names, Corrections, &c., can be received.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

***All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" Printing and Publishing Company, who are proprietors of the well-known "ELECTRICIAN" Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.***

## STEEL-PLATE PORTRAITS

*Of W. H. Preece, F.R.S.; Michael Faraday; Sir John Pender, K.C.M.G.; Sir William Thomson, F.R.S. (Past-President of the Institution of Electrical Engineers); C. H. B. Patey, C.B. (Late Secretary of Telegraphs, G.P.O.); Dr. John Hopkinson, F.R.S. (Past-President of the Institution of Electrical Engineers); Dr. Oliver J. Lodge, F.R.S., and Prof. William Crookes, F.R.S. (President of the Institution of Electrical Engineers), have been issued as Supplements to "THE ELECTRICIAN." A few Copies of these admirably-executed Steel Engravings can be supplied, price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, post free, 4s. 6d.*

## THE COUPLING OF ALTERNATORS.

Much vagueness still exists with regard to the action of alternate-current machines when run in series or parallel on the same circuit, although the generally accepted theory, that of Dr. HOPKINSON, was published as long ago as 1884. That alternators will not run in series, but can be made to run in parallel, has been frequently established by experiments on a large scale, but unexplained cases exist in which it has been found practically impossible to connect them so as to aid each other in feeding a pair of mains, while even where no difficulty occurs in coupling the machines in parallel, the device, in spite of its convenience, is rarely if ever used in practice. The usual plan is that adopted at the Manchester-square Station, where each machine is coupled on to its own system of mains, and the circuits are re-arranged if the loads alter considerably.

The theory which Dr. HOPKINSON put forward in 1884 depended upon the effects of difference of phase. The importance of this quantity in connection with alternating currents is hardly yet fully recognised. It is indeed remarkable what a very slight lag between the amperes and the volts given out by an alternator working at ordinary frequency will reduce

its output to zero just as effectually as if the current were switched off altogether. A 50 horse-power alternator, yielding a current at 100 periods per second, will have its electrical output reduced 20 per cent. if only one-thousandth of a second is made to intervene between the moments at which the volts and amperes attain their greatest values. This means that the engine driving the dynamo, whenever this lag occurs, has over 10 horse-power available to increase the speed of the machine considered merely as a revolving mass. If the current lag has been caused by the dynamo momentarily slowing down, the engine will quickly remedy the defect and the lag will tend to diminish. Otherwise the phase difference will go on increasing and the engine will race. Two independently driven alternators coupled up to the same circuit must tend either towards coincidence of phase, or towards opposition. In the former case they would be suitable for series working, since their volts would add up, while in the latter case they could advantageously be joined in parallel since, just as with accumulators connected in parallel, the currents would add as regards an external circuit, and oppose as regards local circuits. Dr. Hopkinson showed that the self-induction of the circuit, by causing the current to lag behind the resultant electromotive forces due to the two machines, causes the leading dynamo to give out less power than the other, and the engine driving the former machine tends, in consequence, to run faster, so that any difference in phase between the electromotive forces is increased by the effect of self-induction until the state of opposition needed for parallel working is reached.

As, however, was pointed out by Dr. Hopkinson at the time, although the tendency of self-induction is to render parallel working stable, it may not be sufficiently strong to ensure its success. Whether it is so or not must depend upon the mechanical conditions of driving. It is unfortunate that the descriptions which have been given of various successful or unsuccessful attempts at parallel working have rarely contained full particulars of the manner in which the engines have been governed, and of the methods used to couple them with the dynamos. We do not at the moment recall any instance in which parallel working has been successfully accomplished in this country with direct driven machines, and it is possible, since so much must depend upon the flexibility of the driving mechanism, that the explanation of parallel working is to be sought as much in the engines as in the dynamos. The direct driving engines used in this country are not usually provided with sensitive governors. A run-away governor acting on the throttle valve is generally considered sufficient, but the engines used by Ganz and Co., at Leghorn, described in *The Electrician*, Vol. XXV., page 380, which drive the dynamos direct at 250 revolutions per minute, are provided with extremely sensitive governors of the Armington and Sims type. It is desirable that fuller attention should be given to this matter, and also that experiments should be tried with the object of increasing the effect of self-induction in controlling the phase of the two dynamos. Several devices with this latter object in view have been proposed by Mr. Swinburne, most of them being based on the tendency of the currents in the two coils of a transformer to keep in opposite phase. We have not heard, however, that these methods have received much attention experimentally.

Mr. Mordey, who is dissatisfied with the explanation of Dr. Hopkinson, has urged the importance of alternators having a "stiff field" if intended for parallel working. This is not incompatible with the armature having a large self-induction in comparison with its resistance, nor is the presence or absence of iron in the armature of any serious importance when the magnetic circuit of the field magnets is very good, as is the case in machines of recent date. Indeed, Mr. Mordey's alternator, although its field is "stiff," and its coils are free from iron, yet possesses in its armature more than six times as much self-induction in proportion to its resistance as is required by the formula which Dr. Hopkinson has given for the best parallel working conditions. The successful coupling of Mordey machines in parallel is thus no evidence against the old theory; while it is interesting to note that if the theory is correct it should be possible to get alternators to run in series as well as in parallel. Mr. Paul Boucherot, in a recent number of *L'Electricien*, has pointed out that, if a condenser of suitable capacity is placed in series or shunt to the external circuit, the current may be made to attain its maximum value before that of the electromotive forces instead of afterwards, and that the same arguments urged by Dr. Hopkinson to show that parallel working is possible with self-induction in circuit can also be used to show that series working is possible with the aid of condensers. Of the practical value of this idea little can be said at present. Before it can be even tried it is necessary to get condensers capable of withstanding high alternating potentials. We may remind our readers that some valuable and much-needed information in connection with this subject was contributed by Mr. Swinburne in a Paper read recently before the Physical Society. The successful accomplishment of series working by use of condensers would, however, establish the truth of the Hopkinson theory beyond all question.

There is one point in the theory, however, which it seems possible to doubt. The logic of the argument no one can gainsay; but mathematics, however perfect as a process of deduction, can only evolve worthless results from assumptions which are untrue. In the Hopkinson theory it is assumed that the periodic state has been attained before the influence of self-induction is investigated. The effect of putting alternating volts on to a circuit possessing self-induction is ultimately to produce a current which varies in the same way as the volts, but for the first two or three periods this is far from being the case. Extra currents are produced, represented mathematically by exponential functions of the time, whose value is considerable at first and rapidly diminishes as time goes on. The same effect is produced whenever any change is produced in the mean value of the volts or amperes in circuit. We have already pointed out that the actual time corresponding with the difference in phase is exceedingly small, so small, indeed, that the extra non-periodic currents produced whenever any change in phase occurs have not had time to die away. These extra currents are of supreme importance at the instant any change takes place, and their value is appreciable until two or three periods have elapsed. What their influence is on the question it is not very easy to foretell, but as the Hopkinson theory ignores them altogether, it seems desirable that their actions should be investigated, especially in view of the fact that there seems to be a general impression among engineers that the armature resistance is a very important factor in the problem.

Before Mr. Mordey's experiments there was some doubt in the minds of many engineers whether any alternators could be coupled satisfactorily for ordinary use. What he did was acknowledged to be a confirmation of Dr. Hopkinson's theory; how he did it was not clear, but several engineers went home and repeated all the experiments, and said that there was no mystery about it. Most of them now claim "our alternators run in parallel." But there is now nothing extraordinary about this, and the mystery has been shifted to the failure of alternators to run in parallel.

## THE HISTORICAL DEVELOPMENT OF THE INDUCTION COIL AND TRANSFORMER.*

BY DR. J. A. FLEMING, M.A.

The induction coil and the transformer are no exceptions to the general law that improvements in experimental appliances advance along definite lines by a process of evolution in which rudimentary forms are successively replaced by more and more completely developed machines. We are able by careful scrutiny of existing and pre-existing modifications to detect the ideas which have at every step impelled invention forward, and also to examine the prototypes in their relation to the final and fully developed idea. Most readers would probably consider that the proto-typical form of all modern induction coils and transformers was the iron ring with which Faraday made the initial discovery in electro-magnetic induction,† and in one sense this is of course correct, but a careful examination of the early stages of the development of the induction coil as we now possess it seems to show that it is descended in the direct line not from Faraday's ring so much as from Henry's flat spirals, and that it is these latter which are the chiefs of the clan and true ancestors of our modern coil.

Henry's claim to be an independent discoverer of the fundamental fact of electro-magnetic induction is not now disputed. In the July number of *Silliman's American Journal of Science* for 1832, Joseph Henry, then a young teacher in the Albany Academy, gave an account of the manner in which he had independently, and before receiving an account of Faraday's work performed in the previous autumn, elicited from his own great electro-magnet an induced current by wrapping round the soft iron armature certain coils of insulated wire.‡ In the same Paper in which he thus discloses his anticipated discovery he rendered an account of that in which he had in turn anticipated his illustrious rival by the discovery of the fact of the *self-induction* of a spiral conductor, and denoted the phenomenon by the name by which it has since been known. Simply confining himself to the bare statement of the new fact that if the poles of a small battery are joined by a wire a foot long no spark will be found on breaking the circuit, whereas if the wire be thirty or forty feet long, and particularly if it be coiled into a spiral, it gives a bright spark when so employed, Henry noted the discovery and correctly attributed the phenomenon to the induction of the circuit upon itself. Finding, however, that Faraday was following on the same line of discovery he published in the *Journal of the Franklin Institute*, in March, 1835 (Vol. XV., pp. 169-170), a brief epitome of the facts he had collected, and made mention, for the first time, of the use of the spirals of flat copper tape or ribbon, insulated and closely wound together, with which he subsequently conducted his brilliant train of discoveries on the mutual induction of circuits.

A few months later, in the July number of *Silliman's American Journal of Science*, 1835 (Vol. XXVIII., pp. 329-331), he followed this up with a more explicit account of his investigations on the action of a spiral conductor, especially a flat tape spiral, in increasing the spark and the shock from a single cell of a galvanic battery. Using a very large single cell of very low internal resistance known as "Dr. Hare's Calorimotor," he sent the current from this through a spiral conductor formed of copper ribbon about one inch wide and from sixty to one hundred feet long, well covered with silk, and the several spires closely wound on each other. One end of the conductor being attached to one pole of the battery and the other being brought in contact with or rubbed along the rough edge of a plate of metal attached to the other end, he obtained vivid sparks at the place of contact. Moreover he noted that if copper cylinders two inches in diameter and about five inches long, were attached as handles to the ends of the spiral by supplementary wires, and if these cylinders were grasped by moistened hands, a series of sharp shocks was experienced when the end of the spiral conductor was as before drawn along the rough edge of one plate of the calorimotor. This preliminary investigation on the production of a spark and a shock from a single cell of a battery led him to make a thorough investigation of the phenomenon, and in which he most fully explored the whole of the facts. The experiments he recounted in the *Transactions of the American Philosophical Society* for February, 1835, (Vol. V., pp. 223-231); and in *Silliman's American Journal of Science* for July, 1835, covering in these pages a recital of the independent investigations he made in going over the same ground as that occupied by Faraday in his Ninth series of "Electrical Researches" *On the Influences by Induction of an Electric Current on Itself*, sent to the Royal Society in December, 1834, and read in January, 1835. Henry's removal from Albany Academy to Princetown College created an interruption in his researches, but the news of them travelled to England, and in turn created a further wave of discovery. The subject was taken up by William Sturgeon, the inventor of the electro magnet. Sturgeon met one day a Mr. Peaboddy, lately from the United States, in the Adelaide Gallery of Practical Science*, and this gentleman informed him of Henry's experiments on the production of a shock and spark from a single pair of plates in a galvanic cell. Sturgeon was at that time just engaged in launching a new venture, in the shape of his *Annals of Electricity*, a monthly journal devoted especially to electrical science; and in the first volume of this publication, he led off with a paper "On the Electric Shock from a Single Pair of Plates," in which he gave an account of Henry's work and of his own repetition of the experiments (*Sturgeon's Annals*, Vol. I., p. 67). This was published in October, 1836. W. Sturgeon did not appear at this time to have been acquainted with Faraday's Ninth series of Electrical Researches; but after repeating most of Henry's experiments, and adding some of his own, he arrived at the conclusion that the action of the spiral conductor in creating a shock was due to the *collapse* of the magnetic lines of force

* The building, which was formerly the Adelaide Gallery of Practical Science, now survives as Gatti's restaurant in the Strand. It has many interesting electrical reminiscences connected with it. In the Adelaide Gallery Wheatstone performed his classical experiments on the "Velocity of Electricity" in 1834 (*see* "Wheatstone's Scientific Papers," p. 90). In it also Faraday performed the experiments on the Electrical Fish or Gymnotus, and established the real electrical nature of its shock in 1838 (*see* "Electrical Researches," Vol. II., p. 3).

The following extract from EDWARD WALFORD'S "Old and New London" may be of interest.

"Adjoining the Lowther Arcade, with its entrance in Adelaide-street, is the Adelaide Gallery, originally intended as a place of amusement and instruction combined. It was first opened in the year 1830, and named after Queen Adelaide, the consort of William IV. Its varied fortunes from the day when it was opened as a temple of science down to its tranformation into a casino, are thus cleverly sketched by the late Mr. Albert Smith in his little book on 'London Life and Character':—'Some time back—dates are very dry things, so we need not care about the precise year—there existed in the neighbourhood of the Lowther Arcade an establishment called the Adelaide Gallery. It was at first devoted to the diffusion of knowledge. Clever professors were there, teaching elaborate sciences in lectures of twenty minutes each; fearful engines revolved and hissed and quivered, as the fettered steam that formed their entrails grumbled sullenly in its bondage; mice led gasping sub-aqueous lives in diving bells; clock-work steamers ticked round and round a basin perpetually to prove the efficacy of invisible paddle-wheels; and on all sides were clever machines which stray visitors were puzzled to class either as coffee-mills, water wheels, roasting jacks, or musical instruments. There were artful snares laid for giving galvanic shocks to the unwary, steam guns that turned bullets into lead sixpences against the target; and dark microscopic rooms for shaking the principles of teetotallers, by showing the wriggling abominations in a drop of the water which they were supposed daily to gulp down. Then came a transition stage in the existence of the Adelaide Gallery, at first stealthily brought about. The oxy-hydrogen light was slily applied to the comic magic lantern, and laughing gas was made instead of carbonic acid. By degrees music stole in, then wizards, and lastly talented vocal foreigners from Ethiopia and the Pyrenees. Science was driven to her wit's end for a livelihood, but she still endeavoured to appear respectable. . . . And at last all the steam-engines and waterworks were cleared away, and the Adelaide Gallery was devoted entirely to the goddess of the "twinkling feet," and called a casino. It was altered into the Marionette Theatre in 1852, and is now one of the refreshment rooms of Messrs. Gatti."

Digitized by Google

when the current in the coil was interrupted, and that this gave rise to a momentary self-induced current in the coil set in motion by a greater electromotive force than that of the exciting cell. Subsequently he became acquainted with Faraday's prior work on self-induction, and in a critical paper (Sturgeon's *Annals of Electricity*, Vol. I., p. 192) he discusses Faraday's results, and with great skill experiments with a number of coils with and without iron cores, with the object of finding out how much of the "shock" was due to the iron, and how much to the wire coils. On page 283, Vol. I., of the *Annals* there is a full reprint of Henry's Paper read before the American Philosophical Society in February, 1835.

The next important fact seems to have been added by Prof. C. G. Page, of Washington, in the United States, who published an account in *Silliman's American Journal of Science* for October, 1836 (Vol. XXXI., p. 137), of his researches on the self-induction of spiral conductors. Sturgeon abstracted an account of Page's work in his *Annals* (Vol. I., p. 290), and made it available for English readers. Prof. C. G. Page constructed in 1835 a spiral copper strip coil, of which the strip was one inch wide and 220ft. long, carefully insulated, and having terminal wires

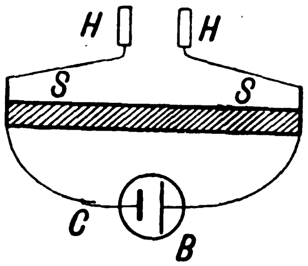

Fig. 1.—Henry's Coil.

soldered at intervals of 55ft. This strip was rolled up into a flat spiral, and mercury cups attached to the six terminal wires.

A single cell of a Hare's calorimotor, or large copper-zinc cell, was then attached to an adjacent pair of terminals, and it was found that on breaking the battery contact sparks and shocks could be procured by touching any of the other terminals in pairs.

The difference between Henry's and Page's arrangements may be indicated by a diagram, in which for clearness the copper strip is represented as unrolled.

Let S S (Fig. 1) be Henry's copper strip coil unrolled, and let B be a galvanic cell, and H H the handles for taking the inductive shock, when the battery circuit is broken at C. In Henry's experiments the arrangement of the coil was such that the self-induction of the whole of it was employed in producing the shock when a person held the handles H H.

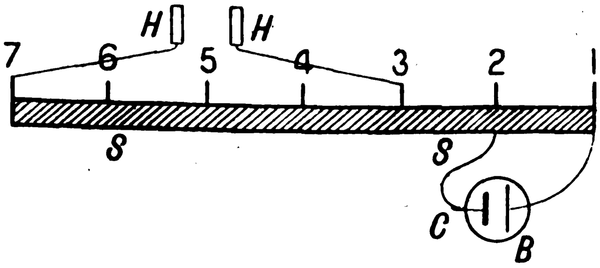

Fig. 2.—Page's Coil.

In Page's arrangement the strip with its six or seven contacts is represented by S S (Fig. 2), and the cell or battery was applied to the terminals 1 and 2. Page found that severe shocks could be obtained by taking hold of metal handles attached to the terminals 7 and 3, or 6 and 5, or 7 and 6, when the battery circuit was broken at C. By making the break and make of contact by rapidly revolving spur wheel he got a succession of sparks from a portion of the strip not included between the battery terminals. In place of a spur wheel he also made and broke contact rapidly by dragging one end of the battery wire over a file or rasp in contact with the plate of the battery.

On page 294 of Vol. I. of the *Annals* Sturgeon explained Page's experiment correctly as due to the induction of one part of the coil on the other. Page really made the first experiment in *auto-induction*, and showed that different parts of the same conductor might act as primary and secondary circuits to each other if in contiguity.

We then come to an important contribution by the Rev. N. J. Callan, of Maynooth College. This investigator followed up with great interest and success the researches of Faraday, Henry, Page, and W. Sturgeon, and on page 295 of Sturgeon's *Annals of Electricity*, Vol. I, we have a Paper by him, written in 1836, "On the best method of making an electro-magnet" "for electrical purposes, and on the vast superiority of the" "electric power of the electro-magnet over the electric power of" "the common magneto-electric machine."

In this Paper Callan describes the construction of an electromagnet with *two separate insulated wires, one thick and the other thin*, wound on the iron core together. He first coiled on a long and thick horseshoe-shaped bar of iron a very *thick copper wire* covered with silk or cotton, and securely over this a very long *thin iron wire*, also insulated with cotton, and one end, viz., the inner end, of the iron wire was joined to the outer end of the copper circuit. In his first magnet the copper wire consisted of a wire 50ft. long and one-twelfth of an inch in diameter, and the iron wire was 1,300ft. long and one-fortieth of an inch in diameter.

He sent a current from a battery of one or two pairs of plates through the thick copper wire, and attached metallic handles to the ends of the iron wire for the purpose of taking a shock, and then on making and breaking the circuit of the battery rapidly he got severe shocks from the iron wire circuit. Here we have the first description that exists of an induction coil with a short thick and a long thin wire upon it; but the peculiarity of it is that the end of the secondary or thin wire is joined to the end of the thick wire, so that they form one circuit wound all in the same direction upon the magnet. Callan's experiment was, therefore, an extension of Page's, and this last, again, was an improvement on Henry's apparatus. Callan followed up this Paper by another dated June 14, 1836, published in Sturgeon's *Annals*, Vol. I., p. 376, being "A description of the most powerful electro-magnet yet constructed." He had forged an iron bar 2½ inches in diameter, 13 feet long, and bent into a horseshoe. It weighed 15 stone. Four hundred and ninety feet of insulated copper wire, one-sixth of an inch in diameter, were wound on it in one layer, and over this a thin insulated copper wire 10,000 feet long and one-fortieth of an inch in diameter; and one end of the thin wire was soldered to one end of the thick wire, so that the whole length of the two wires formed a single circuit, wound all in the same direction on the big horseshoe. The current from 20 large Callan cells (iron cells), or from a Wollaston battery of 280 pairs of plates, was passed through the thick copper wire circuit alone, and rapidly interrupted by an apparatus Callan called a repeater. Wires were soldered to the extremities of the fine wire circuit to receive the induced current. Provided with this formidable apparatus, the inventor proceeded to perform striking experiments with the induced currents. "When by means of an *electro-magnetic repeater* a rapid succession of secondary currents was induced in the fine wire, and passed between charcoal points attached to the ends of the secondary circuit, they were slightly ignited." The shock, as can be imagined, was exceedingly severe, and the ardent experimentalist proceeded to pass from this germinal experiment in the production of an arc light by means of a transformer to an experiment in *electrocution*. For he adds: "Although the" "igniting power of the electric current produced in the long" "coil of thin wire was very feeble, its intensity was exceedingly" "great. When it (the secondary current) was passed through" "the body of a large fowl instant death was produced." This magnet, or one like it, was sent by Callan to Mr. Sturgeon, and by him exhibited to the London Electrical Society at a meeting held on August 5, 1837, and members and visitors enjoyed powerful shocks from the secondary wire of this electromagnetic apparatus.

## THE ELMORE PROCESS.

On Tuesday last, a large party of visitors was invited by the Directors of Elmore's Patent Copper Depositing Company, to inspect their works at Haigh Park, Hunslet, near Leeds. The site chosen for the works is about three miles from Leeds, and is admirably situated, being bounded on one side by a canal and on the other by the Midland Railway Company's line. Two Elmore Companies are located at Hunslet, namely the Depositing Company and the Wire Company, and the land owned by them has an area of no less than 120 acres. The works of the Depositing Company occupy six acres, and are in a fairly complete state; the Wire Company's works are as yet only slightly advanced, but there is evidence enough that a very large concern will eventually be established here.

On arrival at the works the visitors were taken to the generating room, where three high-speed Willans engines are in position, driving one Elwell Parker and three Mather and Platt dynamos, each of which has an output of 37½ kilowatts (50 volts × 750 amperes). The melting shed was next inspected, where the rough Chili bars are melted into a convenient form for handling and placing in the depositing tanks. The method employed is as follows:—The molten metal is poured into a well of water, and becoming granulated in the process, it can be handled as easily as coal or coke, and shovelled into the tanks where required. The depositing sheds were then visited. Here the Elmore process was to be seen in its various stages. At present there are 60 tanks available, each being about 11ft. long by about 3 deep and 2ft. 6in. across. These 60 tanks are all placed in series, and consume on an average a total of some 60 E.H.P. (·9 volt × 750 amperes per tank). The plant at present in operation is capable of dealing with 20 tons of deposited copper per week. The ingenious device of a revolving mandrel and burnisher, employed by Mr. Elmore to secure a dense, fibrous, and cohesive deposit is too well known to require detailed description in the present brief account, and it need only be remarked that the mandrel revolves 20 times a minute, and the continuously moving agate burnisher presses upon it with a weight of about 3lbs. It may be interesting to note that about ½oz. of gold and some 3oz. of silver are recovered in the vats per ton of copper deposited. The visitors were next conducted through the machine shop, where the operation of removing the copper tubes from the mandrels was witnessed, and through the testing-room, extension works, and the buildings in progress for the manufacture of copper strip for wire drawers.

The wire works when completed will have a capacity of 200 tons per week. The whole of the proposed weekly output of these works is, we were given to understand, already bespoken by a powerful group of wire drawers. These works will contain 720 depositing tanks, and the total power required will amount to 2,600 horse-power.

Whatever difference of opinion there may be as to the exact commercial value of the Elmore process, a visit to the works leaves no doubt on our minds that the companies concerned are energetically engaged in building up a most extensive business at Hunslet, and we hope in an early issue to give a complete illustrated description of the works and the process as carried out on a large scale.

## ELECTRIC LIGHTING AT THE GENERAL POST OFFICE.

The two main buildings of the General Post Office devoted to the Postal Branch and to the Telegraph Department have recently been provided with a very complete plant for electric lighting. The lighting commenced in November last and was pushed forward rapidly in order to provide for the great pressure at Christmas. The work is not yet complete, and extensions are being carried out. In the basement of the Postal building is a boiler-room of ample size with a still more commodious dynamo-room adjoining. Three Davey-Paxman locomotive boilers are provided, of which two are used at a time, one being in reserve. The boilers are entirely covered with lagging composition, and the gases pass through downtakes into a large shaft which provides an excellent draught. Opposite the boilers is a coal bunker, from which the coal is shot direct from the street. Water softening apparatus and filter press is provided, since the feed water is taken from the New River Company. In this respect the boilers are at a disadvantage compared with those which work the powerful engines in the Telegraph building for the pneumatic service; these are supplied from a well on the premises, the water from which is exceptionally well suited for steaming. The usual feed water heater, injectors, and feed pumps are provided, together with a tank containing enough water for six hours' supply.

Four continuous-current Elwell-Parker dynamos at present are fixed on massive concrete foundations some 6ft. deep. These dynamos are set in Willans' combination bed-plates, and are coupled to Willans' central valve compound engines. They are extremely compact, more so, indeed, than seems to be necessary, considering the size of the engine-room; and the advantages of the Willans' combination, which are so important in ship work, do not appear in such a case as this to outweigh the importantance of easy access to the brushes and armature and the ready removal of the latter in the case of need.

The engines run under 120lb. of steam, and exhaust into a stack pipe. At present three are used, and one is in reserve. It is intended to add two more engines of the H. H. and two of the G. G. size. Each is capable of delivering 460 amperes at 110 volts. The fields are compound-wound, the shunts being inside the main windings, which consist of four conductors in parallel. The commutators are of ample size, about 9in. diameter by 8½in. long, and have only 48 sections. The main conductors are of high-class Silvertown make, and are led into a chase in the concrete; they are supported by ring-insulators resting on hooks.

The lighting is divided between two machines for the Postal building, while one supplies the telegraph department. The former supplies about 1,000 glow lamps and 36 arc lamps, the pressure being 105 volts. There are about 600 lamps in the telegraph building at 100 volts. The arc lamps are of the Brockie-Pell make, and are run two in series with Brockie-Pell resistance and choking coil. These lamps take about 10 amperes, and run with their usual perfect steadiness. Two are fixed under the portico of the postal building, and on the occasion of our visit nine arcs gave very satisfactory illumination in the large hall of the Inland branch, where six others are used during the busiest hours. The conductors from the dynamos are led up to a large switch-board in the dynamo-room, each conductor coming to the centre of an 8-way switch designed and made in the Post Office workshops. These switches are of the hatchet type, the blade being at right angles to the handle, but working in a plane at right angles to the switchboard. The spring contacts are grouped in a circle on the central plate, forming the end of the conductor, while the eight switches are arranged concentrically around it.

By this switch-board any circuit can be put on to any dynamo. The whole of the circuits are duplicated, and the main cables of 61/12 wire on leaving the dynamo-room, run to other distributing switch-boards in different parts of the building. Here again any branch circuit can be put on any dynamo, or any circuit may be broken.

Cardew voltmeters are used in the engine-room, and Dolivo ammeters. These instruments consist of a solenoid formed of discs, like the old Gaulard-Gibbs transformers, and contain a core of fine iron wire, which moves the needle. Double pole Edison cut-outs are used with rather more profusion than we were prepared for, but in so large a building it would no doubt be difficult to arrange separate lamp-currents from minor distributing boards. The arc lamps are not arranged for lowering, but trestles are used for trimming. The lamp-holders are of the screw socket type, and the fittings are of a plain, substantial character.

It is hardly necessary to say that the electric lighting is immensely appreciated by the *employés*, as many of the rooms were unbearably hot during the long night work with gas. The plant has been inspected by many deputations from provincial and other local authorities, and may be considered a model of its kind.

## "THE DISTRIBUTION OF ELECTRICITY, WITH ESPECIAL REFERENCE TO THE CHELSEA SYSTEM." *

BY MAJOR-GENERAL C. E. WEBBER.

In September, 1889, I read a Paper before the British Association, at Newcastle, on the subject of the Distribution of Electricity in parts of Chelsea and Kensington, with accumulators as the main source of supply. (*The Electrician*, Vol. XXIII., p. 577.)

The Chelsea system was then described as follows :—

(*a*.) Charging the accumulators at high pressure, and discharging for distribution at low pressure, and effecting the changes necessary to the same by special automatic arrangements placed in each storage station.

(*b*.) Supplementing the main supply by means of continuous-current transformers.

(*c*.) Distributing by means of mains laid down in a network.

(*d*.) Maintaining a constant pressure by means of the introduction into the discharge circuit from the storage stations of counter E.M.F. cells.

(*e*.) The use of underground conductors throughout, laid so that the cables can be drawn in and out, and renewed or repaired whenever necessary, without disturbing the ground.

For the benefit of those of my audience who have not already heard a description of the system, diagrams showing the arrangements and connections of the charging units, batteries, and transformer motors are shown on the wall.

First, three of these plants in series charging one of the half batteries in each of three storage stations, the lighting being maintained by the other, or second half battery ; and the pressure in the distributing mains being regulated by cells which give a counter E.M.F.

Second, the three plants are shown charging the second half batteries. Those which having been previously charging are now discharging to the distribution system. Regulation is still maintained as in the first position.

Third, there is a cessation of charging, and the two half batteries are shown to be discharging together in parallel. Regulation is maintained as before.

Fourth, continuous current-transformers are supplying current to the system in parallel with both halves of the batteries.

The apparatus for effecting the various transpositions of the secondary batteries in the storage stations, and for maintaining the pressure constant in the mains, is automatic.

The movable portions are worked by the energy which would otherwise be wasted in the counter E.M.F. cells, which are used for regulating the pressure in the distribution system.

All the actuating portions of the apparatus require current at an E.M.F. of only 4 or 5 volts.

The adolescence of the system being safely reached, the Institution will be naturally desirous to know if the combination described in 1889 as "Accumulation of the main supply from a generating station in storage stations, situated at suitable distances from one another" is a success.

(*a*.) As regards the charging of the accumulators at high pressure, and discharging for distribution at low pressure, and effecting the changes necessary to the same by the special automatic arrangements placed in each storage station. The system designed by Mr. F. King has worked uninterruptedly in each of the four storage stations now in actual use.

The arrangement then described showing three units of generating plant in series, charging one of the half batteries in each of three storage stations, with a current of 75 amperes and 1,500 volts in the charging mains, in combination with the automatic regulating plant by which the changes of the half batteries in and out of charge and discharge are made, have been in daily use.

The mercury cups and contacts have behaved perfectly, and there has been absolute freedom from heating in any of them.

The very small amount of alterations that have been since necessary is a proof of the care with which the Electric Power Storage Company made trial of the regulating apparatus before putting it to work for the Chelsea Company.

(*b*.) The supplementing of the main supply by means of continuous-current transformers is a portion of the system of which our year's experience has gone far enough to satisfy us that it is an efficient and reliable way of providing for the increase in demands for current which the full discharge of the storage stations would be incapable of meeting ; and that the economy arising out of the employment of the generating units, during otherwise idle hours, compensates for the loss in conversion.

The first continuous-current transformer designed for the Electric Construction Corporation was by Mr. F. King.

* Abstract of a Paper read before the Institution of Electrical Engineers, January 22, 1891.

Careful tests, made last August in the presence of Mr. Raworth, engineer of the Brush Electrical Engineering Company, gave the following results :—

| | Primary. | | | Secondary. | | | Efficiency. |
|---|---|---|---|---|---|---|---|
| | Volts. | Amps. | Watts. | Volts. | Amps. | Watts. | Per cent. |
| No. 1 test. | 588 | 64 | 37,632 | 110·5 | 280 | 30,940 | 82 |
| „ 2 „ | 606 | 72·5 | 43,935 | 111·5 | 327 | 36,460 | 82·9 |
| „ 3 „ | 604 | 72·5 | 43,790 | 111·5 | 320 | 35,680 | 81 |

The total weight of the machine (*vide* diagram) is 4 tons, 7 cwt. 2 qrs. The field-magnet armature and shaft are carried on a cast-iron bed and pedestal, having an over-all length of about 6 feet, and a height of about 3 feet 6 inches. The armature is ring-type, carried by a 3½-inch shaft, having two commutators, one at each end. The primary circuit, or motor, commutator has 72 sections ; that for the secondary generation has half that number, namely, 36. The primary circuit on the armature consists of 72 segments, ·120in. diameter copper, well-insulated wire, corresponding to the number of commutator sections, having a conductivity resistance, measured at opposite segments, of ·1755 ohm. The conductor forming each section is wound in an ebonite channel laid between the copper strips which form the secondary, or generator, circuit, and arranged in a single layer on the outside and a double layer on the inside. The secondary, or generator, circuit is composed of copper strips of ·0593 of an inch sectional area, in 36 coils, each of which is connected with a section of the right-hand commutator. The conductivity resistance is ·0087 of an ohm. The core of the armature is composed of charcoal iron rings ·022in. thick, insulated from each other, the external diameter of which is 17¼in., and inside 8¼in. The field magnets are shown in horizontal section in the diagram, the weight of the iron in them being 2 tons 11cwt. 2qrs. They are wound with ·095in. copper, well-insulated wire, in 20 layers, having 2,720 turns on each limb, and have a conductivity resistance of 18·9 ohms, being connected in parallel with the discharging mains.

The machine is connected up on the motor side with the conductors from a unit of generating plant, running with almost the same output as is required to charge one of the half-storage stations of the Chelsea system.

The collectors on the secondary circuit commutator are also connected through switches with the low-pressure distribution systems, having measuring instruments of the output for pressure and quantity.

The behaviour of this machine, both as regards heating and sparking, has been throughout all that can be desired, and as the type improves, we expect an improvement in efficiency.

Mr. King has favoured me with the following remarks :—

"The peculiar advantages of the combination of transformer and battery circuit which is at work at Chelsea are the ability to, at all times, use the transformer to its fullest capacity, and therefore greatest efficiency both of engine, dynamo, and transformer ; and the absolute regularity with which the potential at the secondary, or generator, terminals of the transformer will follow the varying potential at the junction with the feeders to the distributing main.

"It is, of course, easy to see the reason why the machine behaves in the manner indicated. Any fall in the potential of the discharging mains means a reduction in the intensity of the magnetic field in which the armature rotates, and with a constant motor current this reduction of magnetic field means an increase of speed, until the number of revolutions is sufficient to raise the E.M.F. in those mains so as to react on the fields.

"The action of the machine, therefore, is consequent on the intensity of the magnetic field created by the E.M.F. existing at any moment on the discharge mains, and the strength of current in the primary circuit, which will cause variation in speed sufficient always to produce at the secondary armature an E.M.F. equal to that of the discharge at the station."

The method of starting is as follows :—First, the fields are made by switching on the right-hand switch. The engine and dynamo are then connected at the station switch-board through the ordinary charging mains to the motor armature. The engine and dynamo are then started with a resistance in the field, and the speed increased until the required E.M.F. at the dynamo terminals is obtained. The potential at the right-hand, or secondary, terminals will, in consequence, run up to that in the discharge system at the stations. The left-hand switch is then closed, and the current increased in the primary circuit by the gradual removal of resistance at the charging dynamo, until the maximum capacity of the transformer is reached, which will continue irrespective of the amount of storage discharge, upon which all variations of load in the system will then fall.

The Parker (Wolverhampton) C.C. Transformer. The tests of the manufacturers, which have not yet been verified by us with working loads and long continuous runs, show that—

1st. With an output of 1,600 watts, the efficiency is 81½ per cent.
2nd. With 20,000 watts, it reaches 89½ per cent.
3rd. At 40,000 watts, it attains 92 per cent.

The weight of the machine is 5 tons, and the floor space required for it is 7 feet by 3 feet.

The armature is of the drum type. The primary is wound with 200 turns connected up to a commutator with 100 bars. The secondary has 80 turns connected to 40 bars in the commutator at the opposite end. The diameter of the core is 14 and 15-16ths inches, and of the finished armature 16in. Its length is 22in. The winding of the primary is for 540 volts and 75 amperes, and of the secondary 108 volts and 350 amperes, with a speed of 550 revolutions; the resistances of the primary and secondary, and of the magnet, respectively, being ·17, ·001, and 8 ohms.

Laurence & Scott's 40-unit C.C. Transformer. The following description of it has been given me by the makers:—The conductors on the armature are laid in deep and narrow slots milled in the iron plates comprising the core; the low-tension conductor, which is of copper strip, being disposed in the bottom of the slots, with the high-tension, of fine stranded cable, above. There are 88 of these slots, each 1·8 inches deep and ·22 of an inch wide; one of the low and five of the high tension conductors being in each slot. The mechanical advantage of this arrangement is that it is impossible for the conductors to slip over one another to the smallest extent. There are 44 sections in each commutator, the low-tension having one turn per section, and the high-tension five turns.

Ventilation is secured by hollow spaces left between the shaft and each commutator, extending along the shaft to each end of the core, where ½in. spaces are left, extending to the outside of the armature. The paths of the air currents are shown in the diagram by the little arrows. The high and low tension circuits are insulated from one another, and from the armature core, by mica everywhere, except at the vertical ends; and as an additional precaution against the one breaking into the other, caps of brass wire gauze, in electrical connection with the shaft but carefully insulated from the conductors, are arranged between the two windings at the ends, so that before the high could break into the low tension circuit at either end of the armature it must come into contact with one of these caps, and therefore with the frame of the machine. In the core itself the iron plates effect the same object as these caps, as they are purposely put in electrical contact with the shaft.

The weight of the whole machine is 65cwt., and speed 660.

Current-density in high-tension winding with 375 amperes = 2,450 amperes per square inch.

Current-density in low-tension winding with 75 amperes = 2,080 amperes per square inch.

| | | |
|---|---|---|
| Loss in high-tension winding, hot ... | = | 1,425 watts. |
| ,, low ,, ,, ,, ... | = | 945 ,, |
| ,, field magnets ...................... | = | 402 ,, |

| Electrical efficiency ...................... | = | 93·7 per cent. |

Of the endurance or efficiency of this machine I am not as yet in a position to give results.

Of the efficiency of the service to the public in the Chelsea Company's district there has been ample evidence in the contents of a long list of testimonials from customers, which without exception are unanimous in praising the constancy, regularity, and perfect steadiness of the supply.

Questions have been raised in the House of Commons, and in letters to *The Times*, as to the maintenance of the pressure prescribed by the statute in the Chelsea district.

For a few days in December last, the company found itself obliged, for the first time, to cut off the current from their system for short periods in the day, owing to the abnormal exhaustion (*see* figs. 1 and 2) of their reserve of storage, in order to save their accumulator plant from permanent injury.

Before doing so, the Board of Trade and the Local Authorities were communicated with, and the former was told that the step had been rendered unavoidable, not because of want of foresight, but through the delinquency all round of contractors for machinery who had engaged to supply plant early in the autumn. The company offered to lay before that department all the documentary evidence necessary to prove that they had early in the year made ample provision for all conceivable emergencies, and that this late delivery of plant had been the sole cause of the unfortunate position to which they had been brought by the long continuance of foggy weather. In very foggy weather householders use in the day as few gas lights, oil lamps, or candles, as possible, but we find that on such occasions there seems some peculiar temptation to turn on every glow lamp in the house.

Owing to conditions which have nothing to do with the system, and of which a detailed and intelligible narrative would occupy too much time, the nascent period of five months, previous to October 1st, 1889, has been held to be purely experimental.

The variation in the anticipated demand has been marked by its inequality in various parts of the same district. Thus, in one of the new residential gardens in the Chelsea district the custom on one side is rather above the average, whereas on the other side—

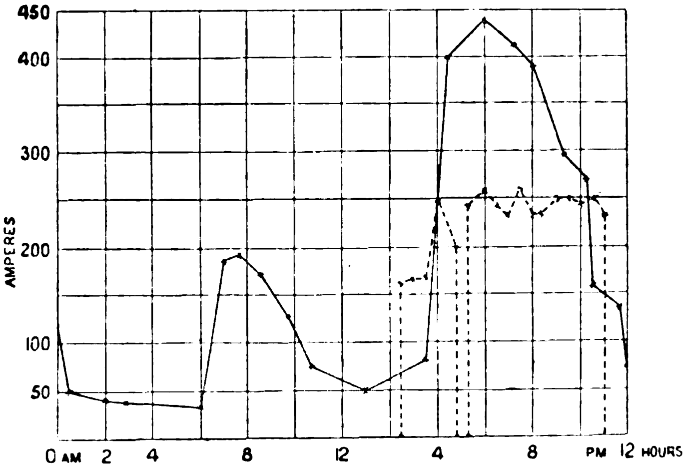

FIG. 1.—Load Curve for 4th December, 1890 (one Storage Station).
———— Discharge from Batteries *only*. Quantity of Electricity Supplied 380 units.
······ Current from C.C. Transformer at same Station, to be added to the Discharge of the Batteries for the Total Discharge.
Quantity of Electricity Supplied 185 units.

consisting of 15 or 20 houses of an average rental of £400 a year, in front of which mains have been lying ready to supply for more than a year—as yet, in only one is current being supplied.

To provide for such contingencies as this in the first instance, would have entailed a first outlay in insulated copper, and a consequent idleness of capital, which prudence forbade. In some cases the growth of demand at certain spots overtook the means of supply, with a temporary sacrifice of maintenance of the full mean statutory pressure.

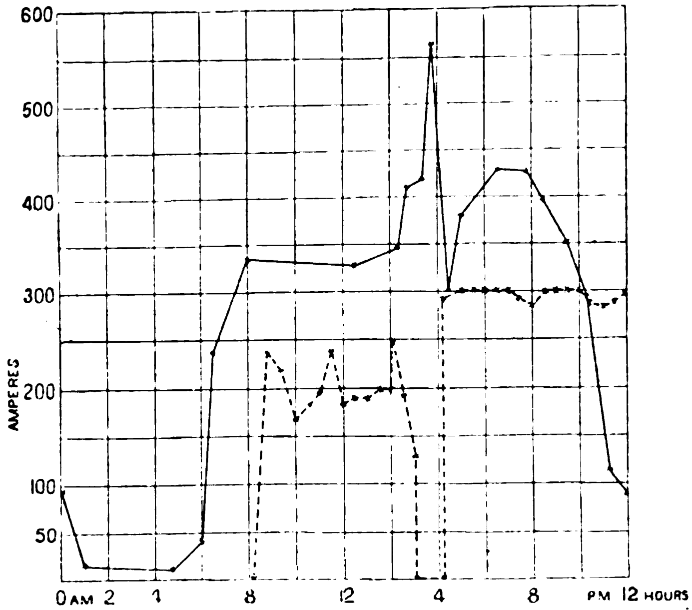

FIG. 2.—Load Curve for 10th December, 1890 (one Storage Station).
*Weather Foggy.*
———— Quantity of Electricity Supplied by Batteries 607 units.
······ Quantity of Electricity Supplied by C.C. Transformer 340 units.

The Chelsea system having started before most others, special experimental Board of Trade rules had to be summarily compiled, and these were more or less on their trial. The authorised rules, which dealt in an important way with the question of constant pressure, were only issued in November last.

The best means of providing for uncertain special demands for current had to be prepared to suit the ordinary conditions of the system, as, owing to its comparative novelty, these could not have been designed before experience had been obtained of the nature that excess.

Digitized by Google

Lastly, in first degree in importance, the Chelsea Company has, in common with other electric supply undertakers, had to make the best of the difficulty which has existed during the past year in obtaining delivery of material in face of the great demand on all electrical manufacturing firms, with a sensible sacrifice of economy in working.

As regards the efficiency of the generating plant, I will remind my hearers that the unit of power is one Willans & Robinson G.G. engine, geared direct to a 40 to 42 unit dynamo, which, running at its normal speed, can yield 70 to 75 amperes at 500 to 550 volts. This plant, when in full use, is run charging a distant storage station from midnight to 3 p.m.; and from 4 p.m. to 11 p.m. It runs, by means of the same charging mains, a C.C. transformer (already described) placed at the same point.

In practice, the yield in the first period is—

38 units during 14 hours = 532 units.

In the second period—

44 units during 7 hours = 308 ,,

Total in the 24 hours = 840 ,,

The tests of our Babcock & Wilcox boilers show an efficiency of 10·2lb. of water per lb. of combustible (ash and firing up being deducted); and also that it has required 5·74lb. of combustible to produce each unit at the terminals of the dynamo.

This corresponds to 3·64lb. per indicated horse-power, a figure which we are in process of reducing, and expect to reduce to 2·7lb.

The average loss in the charging mains, and by conversion with the two means in use, is just 20 per cent., and in the distribution between the converting stations, or sources of supply, and the consumers' terminals is 2 per cent. The 43cwt. of coal used in the generating stations to produce 840 units delivers 690 units into the company's meters, or, as nearly as possible, 7lb. of combustible per unit of electricity sold, which, at 25s. a ton, is less than ·94 of a penny, but which I prefer to take at one penny, per unit, for fuel.

My qualification of this as a report of actual consumption is that, while it is accurate for periods of useful running of the best part of the plant, it is by no means so for those portions which it has not been, for reasons I have given, possible to run efficiently. Experience early showed us in what direction to work to obtain the maximum of efficiency originally claimed by Mr. King for the system, and that course has been, and is being, followed; but necessarily improvements in a plant, which is constantly at work have to be effected with deliberation, and the rate at which they can be carried out more depends on manufacturers than on the suppliers.

The accumulators in our storage stations have now been in use for periods varying from 21 months to nine months.

During these periods the work done each day by each station has varied considerably as between the stations and between the cells.

The routine of testing the 1,800 cells which are, exclusive of reserve, in constant use, need not be described. Completely under control and supervision, it is, as can be understood, of a very perfect kind.

After 18 months' full use, it was found, from tests made by the manufacturers, that one-third of the active material of the positive plates had been exhausted. During the latter six months of the same period—which may be considered a good example of normal rate of waste—the peroxide which has scaled off and fallen to the bottom of the glass cell and been removed has averaged half a pound per month from 15 plates, or half an ounce per plate.

The general conclusion come to is that under the normal circumstances of charge and discharge of the Chelsea system the life of the brown plates can be calculated at three years at least.

The possible leakage from accumulators has been laid some stress on by critics, but, with precautions adopted, our tests on an average shown an insulation resistance to the earth of about 50,000 to 100,000 ohms.

*(To be continued.)*

## THE LIVERPOOL ELECTRIC SUPPLY STATIONS.*

BY A. BROMLEY HOLMES, M.I.C.E.

At the date of formation of the Liverpool Electric Supply Company in January, 1883, there was not a single installation of incandescent lamps in Liverpool. The first station was started in December, 1883, to supply electric light to the Grand and Adelphi Hotels and to other consumers in the neighbourhood, and continued without intermission in daily operation from that date till November, 1890, when the mains were connected to one of the newer stations. In 1887 a larger station was built, and commenced work in December of that year in Tithebarn-street. This now forms part of the Highfield-street station. In September, 1888, the Harrington-street station was completed and at work. In 1889 the Company's new works, offices, and central station were built in Highfield-street, and the supply of electricity began in October of that year. The Company's latest station, in Oldham-place, commenced work in October, 1890.

The following figures show the rapid extension of electric lighting in Liverpool, the number of lamps of 16 candle-power (or their equivalent) connected with the Company's stations being as follows:—

| | | | | |
|---|---|---|---|---|
| On January 1, 1888 ... | 977 | 16 candle-power lamps. | | |
| Do. 1889 ... | 3.330 | do. | do. | |
| Do. 1890 ... | 6.711 | do. | do. | |
| Do. 1891 ... | 11,750 | do. | do. | |

The capacity of the three stations now at work is as follows:—

| | | | |
|---|---|---|---|
| Highfield-street ... | 7,000 | lamps, capable of extension to | 13.000 |
| Harrington-street ... | 4.000 | do. do. do. | 4.000 |
| Oldham-place ... ... | 4,500 | do. do. do. | 20.000 |
| Total ... | 15,500 | Total ... | 37.000 |

The above figures give the number of sixteen-candle-power lamps that the machinery is actually capable of supplying direct at one time; and as experience has shown that never more than 75 per cent. of the lamps connected to the supply mains are in use at any one hour, the above plant would have a working margin of 25 per cent. spare power for the number of lamps stated, without taking into account the storage of electricity always available from the accumulators. The system in use is a direct current continuous supply at a pressure of 110 volts, all the mains being in simple parallel. It may be convenient to give a detailed description of the plant before describing the method of working.

The boilers are 28ft. long, 7ft. 6in. in diameter, and are made of mild steel, each flue being fitted with six steel Galloway tubes. The working pressure is from 110 to 120lbs. per square inch. Of the ten in use seven are fitted with Proctor's mechanical stoker, and the remaining three with Viccar's mechanical stoker.

The engines are Willans' central-valve compound engines of two sizes, ten of them being of the I.I. size, capable of indicating 180 horse-power, the remaining three engines being of the G.G. size, indicating 60 horse-power.

The dynamos have magnets of the single-inverted horse-shoe type, with massive wrought-iron limbs. The armature shafts are coupled directly on to the crank shafts of the engines. The dynamos for the smaller engines give an output of 300 amperes, and an E.M.F. of from 110 to 140 volts, at from 450 to 500 revolutions per minute. The larger dynamos give 900 amperes, and from 115 to 135 volts, at 375 revolutions per minute. Some of the dynamos are compound wound, but the later patterns are plain shunt wound, and all have a variable resistance attached to them, by which the current through the shunt circuit can be varied and the E.M.F. regulated at will. Two of the dynamos were manufactured by Crompton and Co., and the rest by Siemens Brothers.

The accumulators are of two kinds, manufactured respectively by the Electric Construction Corporation and by the Crompton-Howell Electrical Storage Company.

All the distributing mains of the Liverpool Electric Supply Company are laid underground, and have been manufactured and laid by the Callender Company. The largest feeding mains are composed of 91/9 cable and have a sectional area of 1·57 square inches. The conductor is covered with two layers of jute yarn and boiled in refined bitumen. It is next wrapped with parchment tape and covered with a lead casing. The lead is protected by an outside covering of rough jute yarn treated with asphalte and tar. The ordinary feeders are 61/11 cable with an area of ·6 of a square inch and the distributors 37/13 cable ·25 of a square inch in area. In both these mains the copper conductor is covered by a solid sheath of bitite or vulcanised bitumen put on under heavy pressure at one operation. This core is next taped and compounded, and finally braided with hemp yarn and passed through a bath of asphalte compound. The mains are laid in cast-iron troughs ¼-inch thick and about 6ft. long with socket joints. When the troughs are placed in position about ¼in. of refined bitumen in a molten state is run in, and, before setting, spacing bridges of wood are placed in it about 18in. apart. These bridges support the cables and hold them in place, clear of the sides and bottom of the trough and of each other. Bitumen is then run in, so as to entirely cover the cables and fill up the iron troughs to within ½in. of the top. The troughs are then finished by a covering of Portland cement concrete about 1in. think. Strong cast-iron covers are in some cases substituted for the concrete. The service lines from the distributing mains to the consumers' premises are made of 19/14, insulated and covered with lead, and run in wood grooved casing, filled in with bitumen and protected with a hard-wood cover strip.

* Abstract of a Paper read on January 21, 1891, before the Liverpool Engineering Society.

Digitized by Google

The connections of the various lengths of mains to each other, and of the feeders to the distributors, are made by sweating copper lug pieces on to the ends of the cables and by bolting copper connecting bars to the lugs. The distributing mains are jointed in a similar way, the connecting bars being fitted with terminal screws for the attachment of fusible tin strips, to which the service lines are attached. The connections described above are made in cast-iron joint boxes, measuring inside 16in. by 12in. by 12in., provided with socket pieces to receive the ends of the cast-iron troughs in which the mains are laid. Each box has a strong cast-iron cover, held down by a central bronze bolt and cross-bar. A watertight joint is secured by means of a soft indiarubber washer between the cover and the box. All joint boxes are below the level of the pavement, and the surface of the footway is completed by an iron frame and surface plate, by means of which access is afforded to the joint box. In many cases the surface plates are formed in cement to match the adjoining paving.

The general arrangement of mains is as follows:—A pair of distributing mains are laid under the footways on each side of each street, and are connected together to form a complete distributing network, to which are connected all the service lines to consumers' premises. For convenience in working, the network is divided into sections. The supply of current is brought to selected distributing points in this network by heavy feeding mains, which run direct from the generating stations. The feeding mains are so proportioned, relatively to the distance from the station of each distributing point and the number of lamps to be supplied from it, that the percentage of loss in pressure in each feeding main may be as nearly as possible the same; in other words, if the lamps were turned on and off uniformly all over the area of supply, a constant pressure might be obtained throughout the network by varying the E.M.F. of the dynamos at the central station in exact proportion to the amount of current supplied. As a matter of practice, however, the hours of demand vary in different streets and districts, and it is found necessary not only to vary the station pressure as a whole, but also to regulate the pressure for each set of feeders individually.

The following figures will give some idea of the extent of the mains already laid. The length of frontage along which distributing mains are laid is nine and a quarter miles. The total length of single cable used throughout the area is 41 miles. Taking a pair of cables to form a main, the lengths of the various classes of mains are as follows:—

| | |
|---|---|
| Feeding mains ............................................. | 10 miles |
| Distributing mains ........................................ | 9 do. |
| Service lines ................................................ | 1½ do. |
| Total......... | 20½ miles. |

The weight of copper in the mains is 210 tons. The number of joint boxes, service boxes, and pressure wire boxes is 630. The number of separate service lines is 275, but many of these serve for the supply of several consumers.

All the dynamos in a station are arranged to work in parallel on to a pair of positive and negative collecting conductors, and are switched in and out of circuit as the variations in load requires. Each negative feeding main is connected from its cut-out to the station main negative conductor, and each positive feeding main is connected through an ammeter to a main regulating switch. By moving the regulating switch it is possible to introduce accumulators in the circuit of any desired feeder. These accumulators are arranged in opposition to the dynamo current, and, consequently, the pressure in the feeder is reduced by two volts for each cell put into circuit by the regulating switch. This at first sight may appear a wasteful method of regulation, but in practice the load is found to rise so uniformly over the whole area of supply that the amount of energy absorbed in regulation is practically unimportant.

The battery of accumulators at each station is capable of supplying 500 lamps at a time, thus enabling the machinery to be stopped at from 10 to 12 o'clock at night and in some cases entirely on Sunday, and also largely in the day time in summer. The discharge from the accumulators is registered by a recording ammeter. By a special arrangement of dividing the accumulators into sections, devised by the author, they are charged from the dynamos supplying the town at the ordinary working pressure, and by a little care t is in this way possible to so regulate the load on the engines and dynamos as to run them at their highest efficiency.

Continuous tests of the insulation resistance of the mains are made at each station by means of a special apparatus devised by the author for this purpose. If two lamps be connected in series between the positive and negative mains, and a point between the lamps be connected to the earth, the lamps will be found to burn with a variation in brilliancy proportional to the relative insulation resistance of the mains to which each lamp is attached. If two voltmeters be substituted for the lamps, their readings will indicate the same ratio. In the apparatus referred to, a registering voltmeter is used to indicate this ratio continuously. By a suitable arrangement of switches, an ammeter with one terminal connection to earth can be momentarily connected to either main, and the insulation resistance in ohms of the main to which the instrument is not connected is readily arrived at by dividing the station pressure in volts by the number of amperes indicated by the ammeter.

The Hookham electric meter is used by the Company. From diagrams shown it was seen that the number of Board of Trade units used per lamp per month varies from 6·3 units in January to 1·2 units in June. Also, that in December the output reaches 4,000 amperes, whilst in June it does not exceed 500 amperes.

## THE ELECTRICAL TRADES SECTION OF THE LONDON CHAMBER OF COMMERCE.

At a meeting of the Committee of the Electrical Trades Section of the London Chamber of Commerce, held on Monday afternoon last, a prolonged discussion was held with regard to the Board of Trade Provisional Orders relating to telephones. This matter, which is o the highest importance to supply companies, has arisen from certain new clauses which the Board of Trade has seen fit to introduce into the Model Order, superseding the clause in the old 1889 order. It did not appear during the discussion how the modification has arisen. The Secretary, Mr. Murray, read the following:

November 28, 1890.

MODEL CLAUSES FOR PROTECTION OF TELEPHONES, &c.

In the Order of 1889 the provisions for protection of telephones were comprised in the two clauses, which are here printed, so far as material, in ordinary type.

In certain of the Orders of 1890 the words italicised in Clause A were inserted by Mr. Stansfeld's Committee, and the words enclosed in brackets were struck out.

It is proposed in the Orders of 1891 to include in one clause all the special provisions relative to this subject, and to define more clearly the extent of protection.

*Clauses of 1889 and 1890.*

**Systems and Mode of Supply.**

A. Subject to the provisions of this Order and the principal Act, the undertakers may supply energy within the area of supply for all public and private purposes, as defined by the said Act, provided as follows:—(1.) ........... ......................... (2.) ................................... (3.) The Undertakers shall construct their mains and other works of all descriptions, and shall work their undertaking in all respects (with due regard to other) *so as not injuriously to affect the working of any existing* electric circuits from time to time used, or intended to be used, for the purpose of telegraphic, telephonic, or electric signalling communication, or the currents in such circuits; and shall use every reasonable means in the construction of their mains and other works of all descriptions, and the working of their undertaking, to prevent any injurious affection, whether by induction or otherwise, to any electric circuit *used, or intended to be used, for the purposes aforesaid, whether existing at the time of the construction of such mains or other works or not*, or the currents in such circuits. If any question arises as to whether the Undertakers have constructed their mains or other works, or worked their undertaking, in contravention of this sub-section, such question shall be determined by arbitration, and the Undertakers shall be bound to make any alterations in, or additions to, their system which may be directed by the arbitrator.

Provided that nothing in this sub-section contained shall be held to deprive the owners of such electric circuits of any existing rights to proceed against the Undertakers by indictment, action, or otherwise in relation to any of the matters aforesaid.

**For Protection of Telegraphic and Telephonic Wires.**

B. Seven days before commencing to lay down any electric line, or to supply energy through any electric line in any manner whereby the work of telegraphic or telephonic or electric signalling communication through any wires or lines lawfully laid down or placed in any position may be injuriously affected, the Undertakers shall, unless otherwise agreed between the parties interested, give to the body or person for the time being entitled to such wires or lines notice in writing specifying the course, nature, and gauge of such electric lines, and the amount and nature of the currents intended to be sent along the same, and the extent to, and manner in which if at all earth returns are proposed to be used, and the Undertakers shall conform with such reasonable requirements as may from time to time be made by such body or person as aforesaid for the purpose of preventing the communication through such wires or lines from being injuriously affected as aforesaid.

If any difference arises between any such body or person and the Undertakers with respect to the reasonableness of any requirements so made, such differences shall be determined by arbitration.

Provided that nothing in this section shall apply to repairs or renewals of any electric line so long as the course, nature, and gauge of such electric line, and the amount and nature of the current sent along the same, are not altered.

If the Undertakers make default in complying with any of the requirements or restrictions of this section they shall make full compensation to the body or person entitled to any such wire or line for any loss or damage

Digitized by Google

which they may incur by reason thereof, and in addition thereto they shall be liable to a penalty not exceeding five pounds for every such default, and to a daily penalty not exceeding forty shillings. Provided that the Undertakers shall not be subject to any such penalties as aforesaid if the Court having cognisance of the case shall be of opinion that the case was one of emergency, and that the Undertakers complied with the requirements and restrictions of this section, so far as was reasonable under the circumstances, or that the default in question was due to the fact that the Undertakers were ignorant of the position of the wires or lines affected thereby, and that such ignorance was not owing to any negligence on the part of the Undertakers.

*Proposed Clause.*

**For Protection of Telegraphic and Telephonic Wires.**

16. (1) The Undertakers shall take all reasonable precautions in constructing, laying down, and placing their electric lines and other works of all descriptions, and in working their undertaking so as not injuriously to affect, whether by induction or otherwise, the working of any wire or line from time to time used for the purpose of telegraphic, telephonic, or electric signalling communication, or the currents in such wire or line, whether such wire or line be or be not in existence at the time of the laying down or placing of such electric lines or other works. If any question arises between the Undertakers and the owner of any such wire or line as to whether the Undertakers have constructed, laid down, or placed their electric lines or other, works or worked their undertaking in contravention of this sub-section, and as to whether the working of such wire or line, or the current therein, is or is not injuriously affected thereby, such question shall be determined by arbitration, and the arbitrator (unless he is of opinion that such wire or line, not having been so in existence at such time as aforesaid, has been placed in unreasonable proximity to the electric lines or works of the Undertakers) may direct the Undertakers to make any alterations in, or additions to, their system so as to comply with the provisions of this section, and the Undertakers shall make such alterations or additions accordingly.

(2) Seven days before commencing to lay down or place any electric line or to use any electric line, in any manner whereby the work of telegraphic, or telephonic, or electric signalling communication through any wire or line lawfully laid down, or placed in any position, may be injuriously affected, the Undertakers shall, unless otherwise agreed between the parties interested, give to the owner of such wire or line notice in writing specifying the course, nature, and gauge of such electric line, and the manner in which such electric line is intended to be used, and the amount and nature of the currents intended to be transmitted thereby, and the extent to and manner in which (if at all) earth returns are proposed to be used, and any owner entitled to receive such notice may from time to time serve a requisition on the Undertakers requiring them to adopt such precautions as may be therein specified in regard to the laying, placing, or user of such electric line, for the purpose of preventing such injurious affection, and the Undertakers shall conform with such reasonable requirements as may from time to time be made by such owner for the purpose of preventing the communication through such wire or line from being injuriously affected as aforesaid.

If any difference arises between any such owner and the Undertakers with respect to the reasonableness of any requirements so made, such difference shall be determined by arbitration.

Provided that nothing in this sub-section shall apply to repairs or renewals of any electric line so long as the course, nature, and gauge of such electric line, and the amount and nature of the current transmitted thereby are not altered.

(3) If in any case the Undertakers make default in complying with the requirements of this section, they shall make full compensation to every such owner as aforesaid for any loss or damage which they may incur by reason thereof, and in addition thereto they shall be liable to a penalty not exceeding five pounds for every such default, and to a daily penalty not exceeding 40 shillings. Provided that the Undertakers shall not be subject to any such penalties as aforesaid, if the Court, having cognisance of the case shall be of opinion that the case was one of emergency, and that the Undertakers complied with the requirements of this section, so far as was reasonable under the circumstances, or that the default in question was due to the fact that the Undertakers were ignorant of the position of the wire or line affected thereby, and that such ignorance was not owing to any negligence on the part of the Undertakers.

(4) Nothing in this section contained shall be held to deprive any owner of any existing rights to proceed against the Undertakers by indictment, action, or otherwise in relation to any of the matters aforesaid.

(5) In this section the expression "owner" includes any person entitled for the time being to the exclusive use of any such wire or line, as aforesaid.

Colonel Jackson representing the National Telephone Company, stated that to the best of his recollection there was no objection whatever to the old clause, which has been well and carefully considered in committee. He naturally felt that it was difficult for him to speak, since as far as that meeting was concerned he was in a minority of one, and indeed, as far as the Electrical Trades Section of the Chamber of Commerce is constituted, it is obvious that the important interests which he represents are not only very inadequately represented but are completely antagonistic in many respects to those of the Supply Companies. This meagre representation was considerably intensified by the fact that the telephonic interests have been so largely amalgamated, and on these grounds, before any discussion actually commenced, Colonel Jackson strongly protested against any resolution being taken and transmitted through the Council of the Chamber to the Board of Trade. He further stated that he did not think that the amendments had been sent to him. Mr. Sydney Morse remarked that they would be found in the new Model Order, and Mr. Crompton said that on finding that the Board of Trade were taking action in regard to these matters, which so seriously affected them (the supplies companies), they applied as parties interested and obtained the documents which had been read and which it was proposed to discuss. Colonel Jackson objected to a discussion taking place upon clauses whose bearing it was impossible to grasp after merely hearing them read over the table by the secretary. Every member, he said, should receive copies, and all discussions should be postponed until they have had time to give such copies their careful attention. It was, of course, open to those who are interested in the electric light companies to meet together and to make proposals and, indeed, to pass resolutions, but he protested again against drawing any authority of the Chamber of Commerce to such proposals or resolutions, when one of the interested parties was opposed by nineteen-twentieths of the section. Mr. Murray said that he would not fail to bring a strong representation to the Council of the Chamber, if a resolution should be sent up to them.

Mr. Sydney Morse then gave a sketch of the history of the action of the Board of Trade with regard to telephones. The original clause was agreed on by all parties, and related to the possible effects of the induction or leakage of the currents of supply companies upon neighbouring telephone circuits. The Board of Trade sent out a draft of the proposed amendments in November, and he at once forwarded them to the clients for whom he acted. On December 4th he sent in a strong objection to the Board of Trade, who took no notice whatever other than acknowledging the receipt of the communication. They inserted the clause in the City order without giving any notice, but upon the application of the City authorities a ready consent was given to the old agreed clause of 1889, which at the request of the Commissioners of Sewers was restored. It was very remarkable that the Board of Trade should take the initiative and should put forward a clause of this important character, without the request of the telephone companies, or without hearing the interested parties.

Colonel Jackson observed that had he known that Mr. Morse was going to represent the supply companies he would have asked Mr. Winterbotham to accompany him, in order that they might have exchanged ideas. Mr. Sydney Morse and Mr. Medcalf, who were also present, stated that they merely attended as members of the section.

Col. Jackson thought the feeling of the telephone company was that the "agreed clause" of the 1889 order was acceptable, and he was glad to hear that there was no opposition now raised to it. Mr. Garcke called attention to one of the most serious points, which was, that the supply companies may be called on to move their existing mains on account of telephone wires "hereafter to be laid down." Mr. Medcalf, however, pointed out that a proviso was made that the mains must be "constructed with reasonable precautions," and that arbitrators would have to determine what precautions were reasonable. Surely undertakers need not take precautions to avoid laying their mains in streets in the neighbourhood of which telephone wires might some day come.

In reply to an inquiry of a member, who asked for some details of a specific case in which the telephones had been seriously interfered with by induction or leakage from a supply company's system, Col. Jackson mentioned the Hop Exchange where the telephonic communication was seriously affected. Mr. Crompton said that the telephonic communication to his works at Lillie Road was very much disturbed when the House-to-House machinery was running; but he must add that the insulation of their mains was said to be practically perfect, so that the disturbance must be due to induction although the distance between them and the telephone wires was considerable, and that therefore the difficulties of the supply companies in conforming to these clauses would be enormous. He urged upon Col. Jackson that the telephone companies must sooner or later loop their circuits, and that their imperfect service had been hitherto largely, if not entirely, due to the absence of metallic returns, and he thought that if the supply companies hastened the looping they would be doing the best possible service to the telephone companies. Col. Jackson complained that the telephone companies had not statutory powers to lay their mains underground. To loop the overhead wires would inevitably rouse great indignation, but he was looping the communications between the exchanges. It was finally settled that Mr. Morse and Mr. Winterbotham should meet to discuss the clause, and that the engineering or scientific interests should also be represented.

The Board of Trade rules and regulations for overhead wires, formed the subject of a considerable amount of correspondence, and this was ordered to be printed for circulation among the mem-

Digitized by Google

bers of the section and those interested in the matter. It was observed that when these rules were first drawn up they were admitted to be of a tentative character, but the Board of Trade absolutely declined to alter them, and treated them as if they were settled for ever.

Some correspondence had been carried on between the Chamber and the Board of Trade with regard to the Electrical Standards Committee. This consists of a number of very eminent scientific men, but the electrical trades, including both those who make instruments and those who have to use them, were not in any way represented. The Board of Trade replied in most distinct terms, that they did not think it was desirable to add to the number. In a letter dated January 22nd, in reply to a further application, they consented to hear one or two witnesses, but with regard to the addition of names to the Committee they had nothing to add. In the course of a short discusssion, which ensued, strong opinions were expressed as to the action of the Board of Trade in attempting to legislate with regard to such standards without consulting those for whom the standards were to be constructed, and it appeared that to take the evidence of one or two engineers, who were in ignorance of the arguments before the Committee could be of little value.

Letters were read from Messrs. W. T. Goolden and from Major Flood-Page, with regard to a proposed electrical exhibition at St. Pancras, and another, of which Mr. Seymour Wade is the promoter. The feeling of the meeting was unanimously in favour of the opinions expressed in these letters, namely, that such exhibitions would be entirely useless, even if it were not for the fact that the Frankfort Exhibition will fully suffice for any firms who desire to exhibit during this year.

## AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January* 13, 1891.

**The Chicago Exhibition.**—A good deal of interest has been aroused in electrical circles by the various questions that are raised in connection with the coming World's Fair in Chicago. Chief among these is the matter of appointing a suitable head for the electrical section of the exhibition. For the last six months there has been the liveliest kind of wire-pulling going on. Representatives of several prominent electrical companies were boldly advocated for this position, while others endeavoured to secure the appointment of some worthy scientific gentleman as a figurehead. At present, however, the candidate who seems to have the best chance of appointment is Mr. John P. Barrett, the City Electrician of Chicago. Certain electrical interests have bitterly opposed him on account of his uncompromising integrity; but his appointment is now well nigh settled, and will mean a vigorous and successful administration of the electrical section. Mr. Barrett is a man of great executive ability, and his long connection with the City of Chicago, as superintendent of its police and fire-alarm systems, and of its electric lighting and power plants, has given him a firm grasp of the practical side of electricity and an intimate knowledge of American electrical companies and their peculiarities.

**The Westinghouse Company.**—The financial difficulties of the Westinghouse Company, to which I have before alluded, have dropped the stock to a very low figure, but it does not at all mean that either the Company or Mr. Westinghouse is insolvent. A large amount of Preferred Stock is likely to be issued, and the proceeds of the sale of this, together with the half million loan recently negotiated by Mr. Westinghouse, will probably put the electric company on its feet again. It is likely, however, that its future management will be more businesslike and conservative than it has been in the past—that less money will be wasted in lawsuits and tied up in long credits.

**Electric Traction in Philadelphia.**—The city of Philadelphia is at present greatly exercised over the electric traction question. Attempts are being made to secure franchises in certain parts of the city for roads to be operated on the overhead trolley system, and these are being bitterly contested by various persons intimately or remotely interested in storage battery work. Just what the result of the contest will be no one can tell. Philadelphia is now afflicted with cable railroads, and an electric system would certainly be a boon to the travelling public in that city; but the storage battery party is an influential one, and while it has not yet given any evidence of accomplishing anything on its own account it may be able to block the way of its competitors.

NEW YORK, *January* 16, 1891.

**The Westinghouse Company.**—The financial condition of the Westinghouse Electric and Manufacturing Company is being watched with the keenest interest by the electrical public. It is hardly believed that a great and progressive corporation like the Westinghouse, which has done so much for the electrical industry in this country, can be forced to the wall by any temporary embarrassment such as has been produced by a tight Money Market and an extension of work beyond the proper capacity of the cash capitalisation. The Westinghouse Company has expanded its business to an enormous extent, and has apparently tied up its ready money where it is not altogether available. It has a capital of $6,500,000, and its approximate gross earnings for the last year are said to have been no less than $5,000,000. Contracts are rushing in, and the railway department alone has orders aggregating something like a quarter of a million dollars. Nevertheless the fact remains that the company is experiencing considerable difficulty in meeting its obligations. Mr. Westinghouse has thrown his private fortune into the gap, and secured by it the loan of $500,000, which was recently arranged with Pittsburg bankers. Three million dollars of Preferred Stock will be issued, and Mr. Westinghouse has just been in New York engaged in raising money for this purpose. The loan just mentioned is being held in abeyance until the Preferred Stock, or a sufficient quantity of it, can be floated. The advisory board of bankers that control this half million are indisposed to take the heavy administrative responsibility which would fall upon them in protecting their interests, if the company can be extricated from its difficulties by the issue of the Preferred Stock. Mr. Westinghouse's financial standing is of the best, and there is a strong disposition to help him over the present crisis. The real difficulty seems to have been, as I have indicated, that while the capitalisation of each of the Westinghouse companies is large, in the rush of business the ready money has been so far locked up in credits and patent rights that the working capital is hardly sufficient to meet the demands that are made upon it; in addition, an enormous amount has been spent in various lawsuits, not yet terminated, and the pressure of rival concerns have been brought to bear to increase the difficulties that have to be met.

**Electric Soldering Tool.**—A neat invention has just appeared in the shape of an electric soldering iron, and is now in experimental use in the works of a great oil company. At a recent test, its performance was everything that could be desired. It is of the same size, weight, and general shape as the irons ordinarily employed; can be brought up to and kept at the constant temperature that is found most suitable for soldering, and the expenditure of energy is not large, equivalent to about half a dozen incandescent lamps. The arrangement, as might be expected, is a heating resistance placed around the shank which supports a copper head of the form in general use.

**Proposed New Methods of Rapid Transit.**—Active steps have been taken to secure the passage of proper legislation to enable the City of New York to extend its facilities in this direction, and a number of engineers have recently come to the front with all sorts of practical and impracticable plans for securing the desired end. Some of the proposed roads are arcades, occupying nearly the entire space below the surface of the street; others viaducts that will require the purchase of enormous amounts of property; and still others, underground roads of a less pretentious character. The City and South London railway plan is making a very favourable impression here, and seems on the whole to be the most available method as yet suggested. Its cost would probably be about a million dollars a mile, but the engineering and financial difficulties to be met are very much less than in the case of the other suggestions which have thus far been made.

## AUSTRALIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

SYDNEY, *December* 22, 1890.

During the last week the first fatal accident caused from electric lighting machinery occurred at the Sandhurst (Melbourne) station of the Australasian Electrical Company, where one of the assistant electricians in some way, which is not properly explained, received the full current from the dynamo, being killed instantaneously. The published account of the accident says that he caught hold of a switch above the handle, and thus received the shock, but does not explain the matter fully.

In Sydney, the City Council are moving at last in the question of electric light, but whether they are on the right track is open to question. The proposition now before the Aldermen is that a Commission be appointed, consisting of three aldermen and three engineers or electricians, the latter to be selected by ballot of the Aldermen. Should this Commission be appointed, it will probably be some months before their report will be submitted, and from experience of commissions of this kind in New South Wales, it is quite probable that, when submitted, the report will not be of any great assistance to the Council in deciding what had best be done. The Sydney public are now getting tired of dilatory tactics, and it is quite probable that before long a move will be made to force the civic fathers to show their hand.

The installation erected on the Westinghouse system by the Sydney Electric Light Company for the Borough Council of Newcastle will be started this week, and should be a great success, no pains having been spared by the contractors to ensure a thoroughly satisfactory result; the work has been carried out under the immediate supervision of Mr. Hitchcock, who was recommended by the Westinghouse Company, and this alone should be sufficient guarantee that this elsewhere successful system will be given a good send-off on this its trial trip in the Colonies. The street lighting comprises 400 twenty-five candle-power glow lamps, and twenty-three candle-power 2,000 arcs.

Messrs. Harrison and Whiffen, managers for the Crompton Australian Company, are busy carrying out a large installation at the works of the Proprietary Silver Mining Company, Broken Hill, New South Wales, whither Mr. Dymond has now gone to superintend the work. The Central Silver Mining Company, of Broken Hill, has also recently adopted electricity as an illuminant, the Sydney Electric Light Company being the contractors.

## CORRESPONDENCE.

### LAPSE OF THE TELEPHONE PATENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your editorial which appeared December 26, 1890, under the caption, "Lapse of the Telephone Patent," has struck me as being so one-sided, and therefore so unscientific. It presents the case with such partiality, that I venture thus to send a protest across the sea.

It is true that the subject of telephony was "in the air" in 1875, also that a number of physicists were at that time giving the subject much attention, and *therefore*, it seems to me the successful solution of the problem of the electrical transmission of speech was not an *easy* matter. The man finding the solution had accomplished a task upon which the best minds of the day were working. All honour and reward to the man. And surely any unbiased person who reads the records of the great telephone-patent battles fought in this country, must admit that Alexander Graham Bell was second to no man of that day in knowledge of his subject. His invention certainly was the result of patient investigation into the details of the whole science, and of the deliberate application, after long study, of the principles of harmonic telegraphy.

Gray's invention was for the purpose of transmitting articulate speech electrically. Bell applied for a patent to cover certain improvements in multiple telegraphy; but in his specification he distinctly stated, and illustrated the claim by a diagram, that the armature of his instrument could be vibrated by the human voice. Gray was endeavouring to patent a certain method of transmitting speech. Bell was endeavouring to patent a certain method of transmitting harmonic vibrations, speech included, music included, telegraphic signs included. Which was the broader invention?

Gray and Bell filed their applications in the United States Patent Office upon the same day, February 14th, 1876. They used practically the same principle, but different apparatus: nor does an inspection of Gray's first rude sketches strengthen his claims to the honour of priority of invention. A comparison of Bell's drawings with these is alone almost sufficient to convince one of the immense superiority of Bell's knowledge and inventive skill. If, therefore, Bell conceived his invention before Gray conceived his, the former was justly entitled to the patent right because of priority of invention. This was the point to be decided, and in the history of patent and civil law never were the two sides of a question more thoroughly or more ably presented. The whole world has read the decision of an honest and learned court.

It has been proven that several accounts of Bell's invention were published before he had made an application for British Letters Patent. In fact, his instruments were exhibited at the Centennial Exhibition in Philadelphia; so were Gray's: and this was before either had filed in England. Therefore, neither had a right, under British law, to a patent. But if the patent, by some hook or crook, was to be granted to anyone, surely Bell's claim was stronger than Gray's.

Your hymn of praise to Bell's abilities as a business manager is a fine instance of deductive reasoning. Because a man has made money, therefore he is a good manager. *Post hoc, ergo propter hoc!* Surely you have not read the records of the infringement cases the American Bell Telephone Company has fought. Why, the stock of this Company floated a-begging on the Boston Market here for months, with never a purchaser. Very frequently there was not enough money in their treasury to pay the workmen for their work at the end of a week or month. Nothing could better prove Bell's inexperience in those early telephonic days than the *abandon* with which he showed his instruments to all-comers in public and in private, and with which he published accounts of them before he had filed his applications for patents abroad.

Bell *believed* in his invention, worked for it almost to the point of desperation. How heroic was his struggle I have heard from the lips of men and women here and in Providence, Rhode Island, who knew him personally in those days. It forms a near parallel with the early efforts of poor Morse. Yes, it was Bell's indomitable will, his never-failing faith, his opportune luck, which placed the Company upon that sound financial basis that has enabled it to carry the great inventor's fame over the whole earth.—Yours, &c., OTIS K. STUART.

Boston, Mass., January 15, 1891.

### ELECTRIC AND MAGNETIC THEORIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I began of late to feel "blue moulded for want of a batin'," so p. 375 is quite refreshing. In reply to Mr. Heaviside, no doubt I could conceive what he suggests, as I have a fairly vivid imagination. But then the doing so would be doing the very thing I protest against. All I *know* about ether is that it has none of the properties by which we define matter. For my own part, I see no necessity to import it into electrical problems; why should I, then, "conceive" it to be what I know it is not? The people who do so try to conceive it give me no inducement, because they all differ. Ether used to be an infinitely elastic and incompressible fluid, capable of transmitting undulations: when it was dragged into electricity it was discovered that a fluid would not work; then it was made into a jelly, which also would not suit; then it became a mass of rotating wheels, which would lock or slip just as required. Now, as none of these answer (p. 360), Sir W. Thomson "has brought out a new ether, incompressible, with no true rigidity (what about the thousand millions times more rigid than steel?) but with a "quasi rigidity" of any kind required. Well, I will prophesy that when electricians have perfected *their* ether, it will refuse to transmit light, and how shall we get on then?

Clerk Maxwell said "Since the theory of direct action at a distance is mathematically identical with that of action by

Digitized by Google

means of a medium, the actual phenomena may be explained by one theory as well as by the other, *provided suitable hypotheses be introduced when any difficulty occurs.*" Of course, we can explain anything if we may use hypotheses; but are we any wiser? I consider that suggestion a grave crime against scientific morality. It corresponds to passing forged coin, or drawing cheques on a bank where there are no assets. Unfortunately it is becoming a common practice, and all these new notions are constructed by means of this fictitious capital.

Let me assure Prof. S. P. Thompson that I do not feel at all like a fossil. My idea is that it is better to travel by a good sea-worthy ship or a well-built railway than to get into a balloon and be blown about by every "wind of doctrine." I really hope he will not "cast aside" or much modify his excellent little book; if he re-writes it on the new lines it will become "a bar to progress." He will make it into a balloon. I must thank him and Dr. Lodge for a very enjoyable laugh. When I began to write some twenty-five years ago I was denounced as a thorough heretic; all my ideas were wrong, and I was a most presumptuous person. The professors of that day looked down on me as "not orthodox." Now I am told by the professors of this day that I was at that very time "so far ahead of the current science of the time" (Prof. Thompson), and that I had then "arrived by my own methods and insight at various true ideas when the ordinary text-books were very much at sea" (Dr. Lodge). I know that what I then taught as new doctrine has since become "orthodox;" and I have a strong expectation that, in like manner, my present heresy will become the orthodoxy of the future, when the professors return to the recognised ways of true science, and, giving up their cloudy hypotheses and pretended "explanations," recognise that they cannot possibly explain what they do not understand, and so seek patiently for what they can learn from nature.

I should be sorry indeed, to misrepresent any of the sayings of Prof. S. P. Thompson (or anyone). I most earnestly desire to do full justice to every worker in science, and he is a very good one. My reference was to his words (Vol. XXIV., p. 137), "The energy of a so-called electric current is not transferred *longitudinally* along the substance of the conducting wire (as used to be supposed), but is transferred into it sideways, travelling, not along the wire, but across the insulating medium which surrounds it. The truth that insulators convey the energy and do not dissipate it, whilst conductors (so called) dissipate the energy and do not convey it, is a hard saying to the half-educated electrician." He also says, "No electrician who has taken the trouble to study the facts, and has the capacity to follow their inescapable consequences, can fail to learn" all this. Well, I have taken a great deal of trouble (not over the facts, for I cannot discover that anyone has shown them), and as to capacity, that is a matter of opinion; but I am ready to maintain that the old doctrines are the truth, and the new ones cunningly devised fables; that the so called conductor *is* the conductor of current and of energy; that the insulator and surrounding medium do dissipate and do not conduct energy *longitudinally;* that they in no degree transmit the energy from the source to the work, as the new doctrines teach, but that they produce, as Faraday taught, and as everyone believed, till mere hypothesis overrode observation and induction, *retardation* of current and *loss* of energy.

In reply to specific questions. Yes, I will maintain "that Ohm's law, pure and simple, is applicable to alternating currents." But *distinguo*, as the casuists say; let us clearly separate form and substance—the law, which corresponds to the facts of nature, and formulæ, which apply it to specific conditions. When a "variable period" is under consideration a variable function operates, and must be represented in the formula without affecting the law.

No. I certainly will not fly in the face of facts; they are all on my side. But Prof. Thompson has shifted his ground. He questions me now as to the transfer of energy *laterally* through the medium. But that is dissipation of energy—retardation. The point in debate is the *longitudinal* transfer of energy. That makes all the difference; the lateral effects of the current are among the most important data in all my teachings, a fundamental element of my theory that the molecular and atomic structure of matter and the effects of energy among the molecules and atoms amply explain all the real facts of electricity.

But I cannot pretend to treat the subject itself now, as I must needs employ illustrations, so I will defer the attempt.—Yours, &c., JOHN T. SPRAGUE.

## BOULT'S WIRE TABLE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am much obliged for the care with which your review of this table has been prepared, and glad to find your testimony added as to its usefulness. Will you kindly allow me a few words in explanation, called for by some of your remarks?

Although the number of columns is, as you say, 452, the number of conductors dealt with is 469, owing to different gauges containing in a few cases conductors of exactly the same size. In these cases the names of the gauges are put side by side in the same column—*vide* columns Nos. 387, 390, &c. The size of page is crown 4to., not folio.

Your objection to "circular mils" is answered by the fact that, whatever may be thought of this method of expressing the area, it is largely used in America, and, if omitted, the *international* character of the table would have been lost; and it is the readiness with which particulars given in the system of one country are converted into that of another country that constitutes a special feature of the book.

Coming now to the small discrepancies pointed out in regard to stranded cables. As explained in the preface, the allowance for lay of strands has, in the case of S.W.G. cables, been copied from the list of the Silvertown Company, while in other cases "a very close approximation" has been obtained by the addition of suitable percentages. This is the best I could do, and is, I am sure, all that is required for practical purposes.

In regard to resistance, I have, as you point out, simply followed the usual custom, and, in default of an authoritative statement on the subject, cannot see what other course was open; though agreeing with you that the resistance of a single strand (I presume you mean only the net length of the cable), divided by the number of strands in the cable, would give a "safer" figure. The difficulty is that it might be too safe.—Yours, &c., W. S. BOULT.

Liverpool, January 24, 1891.

# LEGAL INTELLIGENCE.

### Allison v. the City and South London Railway Company.

On Friday last Mr. RENSHAW, Q.C., mentioned the above matter to Mr. Justice Kekewich, in the Chancery Division of the High Court of Justice. He said he appeared for the plaintiff, Mr. Allison, who was one of the trustees of Mr. Spurgeon's home for poor boys (the Stockwell Orphanage), and the object of the application was to obtain an injunction restraining the defendant Company from so working their railway as to become a nuisance. The defendants worked their railway by electricity, and the noise that was caused in the generation of the motive power had become so great as to be a nuisance to most people in the neighbourhood, but particularly to the Institution of which the plaintiff was a trustee. Since the notice of motion had been served an undertaking had been entered into by the Company by which they bound themselves not to work their engines or machinery, between the hours of 11 o'clock at night and six in the morning, in such a way as to cause complaint, over next motion day. These terms the plaintiff was willing to accept, and the motion therefore stood over until to-day.

### United Telephone Company and Another v. Andrew Erskine Muirhead.

In this action the United Telephone Company and the National Telephone Company sue Andrew Erskine Muirhead, merchant, Cart Forge, Crossmyloof, Glasgow, in the Scotch Courts, to have the defender interdicted from infringing the letters-patent, dated July, 1877, granted to Thomas Alva Edison, of Munlo Park, New Jersey, U.S.A., for the invention of "improvements in instruments for controlling by sound the transmission of electric currents, and the production of corresponding sounds at a distance," and from making, using, and exercising or vending during the continuance of the letters-patent the invention described therein. £500 is sought in name of damages for the alleged infringement, and delivery is also sought of all instruments possessed or controlled by the pursuer, including the "Ader" transmitters, which are made in infringement of the letters-

Digitized by Google

patent, and also all instruments made according to the manner described in the letters-patent dated December, 1876, granted to William Morgan, of Brandon and Morgan-Brown, engineers, London and Paris, for the invention of "improvements in electric telephony (transmitting or causing sounds for telegraphing messages) and telephonic apparatus," a communication from abroad by Alexander Graham Bell, of Boston University, U.S.A. The letters-patent in question are vested in the United Telephone Company, subject to certain rights to the National Telephone Company. The pursuers say that the defender has been violating their letters-patent by erecting telephone transmitters and receivers of the "Ader" type. The defender says that the statements of the pursuers, so far as material, are unfounded in fact, and that he ought to be assoilzied.

The record was closed on Saturday, and the case sent to the Procedure Roll.

## TRADE NOTES AND NOTICES.

Sale by Tender.—We have received from Messrs. Wheatley, Kirk, Price, and Goulty, a schedule of the British and Foreign Patents, fixed and loose Plant, &c., connected with Messrs. Smith and Moore's patent safety system of coal getting, which are on sale by public tender. Tenders should be sent in to 52, Queen Victoria-street, London, E.C., not later than Noon on Monday, the 2nd February.

Eastern Electric Light and Power Company, Limited (in Liquidation).—A meeting of the creditors of this Company is to be held at the offices of Mr. Latimer Clark, 11, Victoria-street, London, S.W., on March 2nd, at 1 p.m., to receive the liquidators' accounts.

Casings for Electric Wires.—Mr. F. A. Fawkes, of Chelmsford, sends us an illustrated list of casings arranged for use as skirtings, dado rails, picture rails, cornices, &c. Some of these are enriched with composition ornaments of excellent design. The grooves for the wires are parabolic, and the capping is thick enough to prevent curling.

## COMPANIES' MEETINGS.

### Elmore's Foreign and Colonial Patent Copper Depositing Company (Limited).

The second annual ordinary general meeting of this Company was held at the Cannon-street Hotel yesterday, Sir John H. Morris presiding.

The SECRETARY (Mr. J. Shurmer) read the notice calling the meeting, and the Directors' report and statement of accounts were taken as read.

The CHAIRMAN said that the position and prospects of the Company as they stood on December 31st last were set forth at such length in the report and accounts which had been circulated among the shareholders that there was not very much left for him to say on the present occasion. He must, however, congratulate the shareholders on the realisation of the hopes held out by him at the first general meeting of the Company held in October, 1889, when he stated that the Directors had the fullest confidence in the value of the Elmore inventions, and that, declining to negotiate the sale of the foreign patents until the success of the Company had been proved in this country, they would be able to obtain much better prices for them than if they disposed of them at once. This had proved to be the case. The success of the Elmore Company had, he thought, been clearly shown by the Company in this country, and they were now in a position to estimate pretty clearly the value of their patents for the various countries to which they wished to dispose of them. They had already, as the shareholders were aware, during the past year disposed of the patents for France, Austro-Hungary and Germany, and had thereby acquired a considerable sum from which they had already paid £4 per share to the priority shareholders, and they now proposed to pay another £1. They also hoped during the course of the present year to dispose of patents to two or three other countries, and if their hopes were realised, they trusted to obtain thereby a further sum, which would enable them to pay another £5 to the holders of the priority shares, and also leave sufficient to pay some dividend to the holders of the founders' shares. Before proceeding to notice the balance-sheet and profit and loss account, he wished to say a few words on the issue of £50,000 Debenture Stock by the French Elmore Company which this Company had agreed to take from that Company. It had been remarked to him by more than one of the shareholders that they saw no reason why they should have agreed to take this large amount of Debenture Stock from the French Company, and that it would have been much better to have left that Company to get any further capital it might require, either from its own shareholders or the investing public. He wished, therefore, to say a few words as to their reasons for acting as they did. On the formation of the French Company it was found to be of the greatest importance not only in the interests of that Company, but also indirectly in those of this Company, to secure the services of M. Secrétan as manager of the French Company. It was also found that those services could not be secured without at least £50,000 more working capital being raised, and it was, thirdly, discovered that in the then unsatisfactory state of the Money Market it was not possible to obtain this sum either from the investing public or from the shareholders of the French Company. There was nothing, therefore, left for the Directors, on an application from that Company, but to agree to advance this sum, provided that they were satisfied with the nature of the security offered to them. That security was that the Debentures should be secured by a first floating charge on the whole of the assets of the French Company; that they should pay interest at the rate of 6 per cent.; that the £50,000 advanced should be repaid within three years from the 1st of January of the present year—that was to say, by the 1st of January, 1894—or within any shorter period at the option of the French Company; and that they should be paid off at the rate of £105 for every £100 of stock. The Board considered those terms favourably, and while they were of opinion that the security was good, and that it was very much to their interests to promote those of the French Company, they agreed, especially as they held 33,000 shares of that Company, to these terms. The Directors were of opinion that the security offered by those Debentures was very good, and that the Debentures themselves were a very good and safe investment, so much so that applications had already been made to them on behalf of the French and their own Company to take up a portion or the whole of these Debentures. They proposed, therefore, to issue a circular to their own shareholders, and also to those of the French Company, offering them the Debentures on the same terms on which the Directors themselves accepted them; and he had only to add that, in the event of any considerable portion being subscribed, they would be in possession of a further amount of funds, which would enable them to pay a further cash dividend to the holders of priority shares. He trusted, therefore, that the action of the Board in offering to take up that £50,000 of Debentures of the French Company would meet with the approval of the shareholders. Taking the profit and loss account on the credit side, the first item, as they would see, was that the net amount received by the Company from the sale of its French, Austro-Hungarian, and German patents was £257,750. From this amount they had deducted £30,000, to represent the original capital value of the patents sold, leaving a net amount, after adding certain items of interest and transfer fees, of £228,341. Upon the debit side of the same account the balance brought forward was £1,879, being the deficit in respect of the first nine months of the Company's existence, during which, as they were aware for the reasons he had given them, no patents were disposed of. The next item was Directors' fees, and was fixed in accordance with the Articles of Association, and the succeeding one was maintenance of patents and legal charges. Owing to the large number of patents they held, the maintenance and legal charges amounted to the considerable sum of £1,270. After allowing for sundry working expenses, there was a balance carried down of £222,772. Out of this amount they had already paid an interim dividend of £4 a share on the priority shares, which absorbed £60,000, and under Clause 72 of the Articles of Association the Directors were entitled after the payment of a certain dividend to £10,605. This amount might appear very large, and probably they would be very much questioned about it. At the same time, he might point out that the amount was fixed by the Articles of Association, and he could hardly see that the Directors had any option in the matter unless the shareholders called upon them to forfeit the amount. Some might think that the work done for it was inadequate, but he could only say, having had a great deal of trouble and anxiety, and having spent many sleepless nights in connection with the Company, he did not think that their remuneration was altogether unearned. He believed that, strictly speaking, they were entitled to this amount in cash, but he need hardly say that they did not intend in any way to insist on that. It might be distributed to them partly in cash and partly in shares and Debentures as might be found convenient to the Company, and most conducive to its interests. The Directors would be prepared to take the amount in any way the shareholders might desire. Turning to the credit side of the balance sheet, they found the purchase of patents accounts credited with £110,000, which they had reduced to £80,000, by writing off £30,000, which represented the original capital value of the patents sold. Sundry debtors amounted to £22,722, but as the accounts were made up to December 31st last, he might inform them that this amount had since been paid off in full. The securities next shown were Elmore's French Company, 33,250 shares of £2 each, or £66,500; Elmore's Austrian Company, 31,075 shares of £2 each, or £62,150; and debentures in the latter, £50,000. The shares were valued at their nominal value and the debentures at par whereas they stood now at a higher price in the market, and would increase in value. The French Company's works were being rapidly pushed forward, and the contractors were under a penalty to complete the same by the end of May; and, in fact, according to the report of Mr. Secrétan, they would be in operation by the end of June next. The Austro-Hungarian Company had also selected admirable works, and had every hope of getting to work shortly after the French Company. The cash on hand and at the bankers amounted to £37,691, office furniture and fixtures £128, making a total at the credit side of the balance-sheet of £319,192. The share capital amounted to £120,000, and the various creditors at the date of making up the accounts represented £47,025. This item might require a little explanation. It consisted of three principal items. The first was a certain amount which was then due, but since paid off, on account of promoting, undertaking, and bringing out the French and Austrian companies; secondly, a percentage due to the Directors, as shown under the profit and loss account; and, thirdly, income-tax due to the Commissioner of Inland Revenue. There was only one other point on which he would like to say a few words. It was a question of very great importance, and he would be glad either now or at some future time to be favoured with the views and, if necessary, the advice of the shareholders upon it. It was the question of the realisation of the securities held by the Company. They would recollect that the matter was taken up and noticed particularly in a circular issued to them on November 13th last. Having referred to the salient features of the subject, as dealt with by the circular in question, he went on to say that there were three courses open to them. The first was the formation of an Elmore Trust Company; the second was that they should hold the shares themselves, realise the profits from them, and distribute these profits among the shareholders; and the third was that they should hold a special meeting, and alter the articles of association, and so become empowered to distribute those shares just in the same way

Digitized by Google

as if they were cash. It was a matter that would require very great consideration on the part of them all. The Directors would be prepared to meet the shareholders and discuss the subject with them before coming to any final decision. At any rate, before any decision was come to the shareholders would be fully taken into their confidence.

He concluded by moving the adoption of the report and accounts.

Mr. MACFARLAN seconded the motion.

Mr. HOSTER spoke at some length on the question of the expediency of the realisation of the Company's surplus capital, merely keeping something in hand for working capital, and moved an amendment to this effect. He considered the Company's property one of the finest he had ever known.

Mr. SIMPSON seconded the amendment.

The SOLICITOR pointed out that the amendment was out of order, and could not be put to the meeting; and that, until the Articles of Association were altered, they would have to go to the Court of Chancery for power to divide the funds in question. He suggested as an alternative course that a small committee of shareholders might be formed to confer with the Directors as to the best way of providing for the distribution of their assets, and when that was done the recommendations of the Directors and of such committee might be submitted to a meeting of the shareholders.

Mr. LOUIS RANDALL then proposed, and Mr. CHANCE seconded, an amendment, in effect requesting the Directors to consider the practicability of making a distribution of the money among the shareholders, and meantime adjourning the discussion on the report and accounts till a future meeting.

Mr. F. L. RAWSON gave a short statement as to the company's patents, after which

The CHAIRMAN put the amendment to the meeting, which he declared lost.

The substantive motion for the adoption of the report and accounts was afterwards put, and declared carried.

The CHAIRMAN then moved—

"*That a dividend of* 20 *per cent., or* £1 *per share, less income tax, be paid on the February* 4*th next on the Priority Share Capital, making, with the interim dividend of* £4 *a share, paid on the December* 8*th last, a total dividend of* 100 *per cent. for the nine months ending December last.*"

Mr. E. J. CARSON seconded the resolution, which was agreed to.

The sense of the meeting was then taken as to whether a committee of shareholders should be appointed to discuss with the directors the question of the distribution of the surplus profits of the Company, or whether it should be left to the Board to submit recommendations to a special meeting to be subsequently convened.

The CHAIRMAN declared the show of hands in favour of the latter course, adding that if he saw his way to have the distribution made legally in the interests of the shareholders, he would do his best to have it done. It was a very thorny question, and one which would give them a great deal of trouble. At any rate, a special meeting would be called and the subject discussed.

The retiring Directors, Messrs. William Elmore, George Holmes, and John Macfarlan, were afterwards re-elected, as were also the Auditors, Messrs. Pixley & Co.

The following resolution, which was passed by the shareholders in general meeting on December 29, 1890:—

"*That once at least in every year the Board of Directors shall lay before the Company in General Meeting a statement of the income and expenditure for the past year, made up to December* 31*st, then last past, instead of to March* 31*st, as provided in Clause* 113 *of the Company's Articles of Association,*"

was, on the motion of the CHAIRMAN, seconded by Mr. CARSON, confirmed as a special resolution.

The CHAIRMAN, in reply to a vote of thanks to himself and the Board, proposed by Mr. Hoster, and seconded by the Solicitor, said that if the Directors were not, perhaps, deserving of all the praise which had been showered upon them by the proposer and seconder of the resolution, no one could have been more anxious to promote the interests of the Company than they were, and they would, he hoped, continue to be so.

The proceedings then terminated.

## Elmore's Austro-Hungarian Patent Copper Depositing Company (Limited).

The SECRETARY (Mr. J. Shurmer) having read the notice convening the meeting,

The CHAIRMAN said: It is quite needless in a meeting of shareholders in the City of London to tell them what a statutory meeting is; but I will say what it is not, and that is, that under ordinary circumstances it is not a meeting for business. Usually the shareholders and Directors meet face to face, the Chairman makes some statement as to what has been done since the Company was registered, makes his bow, and the meeting is at an end. But to-day the Board have thought it well to utilise the meeting to avoid calling you together on another occasion by placing before you the resolutions which you have just heard read. With regard to these resolutions, I defer any reference to them until I have said a few words as to what your Directors have done since they were entrusted with the management of your affairs. The Company was registered nearly four months ago, and we have had in that time to meet very frequently to get through the number of legal formalities which are necessary from the nature of this Company. You may, of course, be very well aware that it is much easier to start a company to do business in England than it is to start an English company in a foreign land to do business in that land; and especially as this business is based upon patents we had the formalities in reference to them to get through besides to get the necessary Government licence for trading. In order to do that a solicitor has taken the proper steps. I may say before that that as far as the English formalities go everything has been done and is perfectly complete. We have taken the absolute transfer of the Austro-Hungarian patents, and in regard to Austria itself everything is going on as fast as possible through the assistance of our legal representative in Vienna. But again another difficulty arises, inasmuch as that is a sort of double-barrelled country. You may well understand that we have had a great deal to do in arranging for getting through the earlier stages of the matter, but at the same time we have not been idle with regard to the carrying on of the business. We have not waited for the completion of these formalities before setting to work. Our General Manager, Mr. Stephen Rawson, has been in Austro-Hungary, and has inspected a number of sites for works, and taken into consideration the commercial and geographical advantages or disadvantages of all the different sites offered to us. Under his advice, we have gone so far as this, that we have decided, provisionally of course, upon a site in a remarkably good situation for the transport both of our raw material and finished products, as well as for cheapness of fuel and abundance of labour, and we have the option of land for our purposes in the site that I refer to. We have also negotiations in hand for a portion of our work being carried on through existing industrial agencies, which I would rather, however, not refer to now, more particularly as it might interfere with the progress of the negotiations. As regards Germany, you are aware by the circular which has been addressed to you that not long after we started the Austro-Hungarian Company we had an opportunity of acquiring the German wire patents and the other rights arising from them and from the Elmore process generally in Germany. We thought it was of extreme importance that we should acquire these rights, because Germany is really a larger field for this kind of manu-

facture than Austro-Hungary, and we hope probably better progress there than in Hungary. We have arrived at this stage that we are at the present moment in close negotiation for acquiring a very large and suitable manufactory which was built for another purpose on an exceedingly good site both for transport and other purposes. The manufactory is large and new, one portion of it being not quite finished. It has besides this most important feature: it has 550 horse-power of water-power, turbines quite new and perfectly fitted up with all the gear belonging to them. One important point in connection with the water supply which to any practical man is of great importance is that the dam in which our supply rests is not likely to break away as it is a natural rock. Besides that it has steam power, boiler power, and a fine chimney 100 feet high—in fact, everything necessary for our purpose—and Mr. Elmore, one of our colleagues and the founder of this process, is now in Germany with the object of completing the arrangements and obtaining the necessary plant, dynamos, and other mechinery. I have myself important letters from him in which he writes in the strongest way as to the importance of the property. Mr. Elmore went to Germany for the purpose of examining the different sites. He went there to meet a friend of mine and the result is what I am stating, that we are on the point of settling terms for this important site, and although we have not, like the French Company, a M. Secrétan to assist us, or a Hercules to call in to our aid, we are putting our own shoulders to the wheel, and we believe that if we do not beat the French Company we shall run a good second in the race. With regard to the process itself, I may take it for granted that you all know it. It is the manufacture of copper articles by a process which almost takes them from the raw and puts them into a finished state by natural and automatic means. It is a wonderful process. I have seen it myself, and I believe nothing more beautiful was ever invented. With regard to its value we have abundant authority from experts in this country, such as Dr. John Hopkinson, who reports in the highest terms as to its merits. We have also the testimony of such a practical man as M. Secrétan, an eminent French copper authority, as to its commercial value. We have allotted 50,000 shares, and they are largely paid up, much more so than we expected. They are allotted to about 580 shareholders, a tolerably large *clientèle*, and I am surprised not to see more of them here to-day. I think, however, when we see a meeting of this kind sparsely attended, it is *prima facie* evidence that the shareholders have confidence in the concern.

The following resolutions, proposed by the CHAIRMAN, and seconded by Mr. MACFARLANE, were then unanimously agreed to:—

"*That the name of the Company be changed to Elmore's German and Austro-Hungarian Metal Company (Limited).*

"*That Article 84 of the Company's Articles of Association be rescinded, and that the following new article be inserted in lieu thereof:—*

"*That the following clause be substituted for Article 84:—' The qualification of a Director shall be the holding of 200 shares of the Company; a first Director may act before acquiring his qualification, but shall in any case acquire the same within one month from his appointment, and unless he shall do so he shall be deemed to have agreed to take the said shares from the Company, and the same shall be forthwith allotted to him accordingly.'*

"*That Article 107 of the Company's Articles of Association be altered by omitting the following words at the commencement thereof:—*

"*'Notwithstanding anything in the last preceding article contained, or any rule of law or equity to the contrary.'*"

## NEW COMPANIES REGISTERED.

**LEEDS COPPER COMPANY (LIMITED).**—Registered by Kerly, Son and Verden, 14, Great Winchester-street, E.C., with a capital of £450,000 in £1 shares. Object, to acquire the undertaking of the Excelsior Copper Company (Limited) incorporated in 1888, including certain mines, mining claims, water and other rights and properties situate in the county of Megantic, in the Province of Quebec, Canada, and for such purposes to carry into effect an agreement made between the Excelsior Copper Company (Limited) of the first part, Charles Harrison Smith (the liquidator of the Company) of the second part, and the Company of the third part.

**NEW YORK BELTING AND PACKING COMPANY (LIMITED).**—The prospectus of this Company was issued early this week, and applications were invited for 7,000 ordinary shares of £10 each, 9,500 Preference shares of £10 each, and 1,000 Founders' shares of £1 each, being a portion of a total capital of £651,000, divided into £426,000 share capital, and £225,000 First Mortgage Debentures. The Preference shares are entitled to an 8 per cent. preferential dividend, and are also preferential as to capital. The ordinary shares are entitled to dividends up to 12 per cent., and the balance of profits (if any) is divisible, half to the ordinary shareholders and half to the holders of Founders' shares. The Debentures are divided into 2,250 Six per Cent. Debentures of £100 each, of which the present issue is 1,350. Interest is payable half-yearly, on January 1st and July 1st. Amongst the Directors are Mr. Samuel Pope, Q.C., Chairman of the International Okonite Company (Limited) and Director of Woodhouse and Rawson United (Limited). The Company is established to acquire the business of the New York Belting and Packing Company, of Connecticut, U.S.A., manufacturers of all kinds of india-rubber goods, &c. The lists opened on Monday last, and closed yesterday (Thursday) for London, New York, and Boston.

## CITY NOTES, &c.

**BRAZILIAN SUBMARINE TELEGRAPH COMPANY.**—The receipts of this Company for the week ended December 26th amounted to £6,367.

**CITY AND SOUTH LONDON RAILWAY COMPANY.**—The receipts of this Company for the week ended January 24th amounted to £742.

**ELECTRICITY SUPPLY COMPANY FOR SPAIN (LIMITED).**—This Company announce the issue of £75,000 Six per Cent. First Mortgage Debentures of £100 each, the price of issue being 98, payable as follows: £10 per debenture on application, £20 on allotment, £30 on March 2nd, and £38 on May 15th. The interest is payable half-yearly on January 1 and July 1, and the debentures are to be paid off at par on January 1st, 1901, or before that date, at the Company's option, at the price of £105 per £100 Debenture on six months' notice. The Company was formed in October, 1889, with a share capital of £100,000, which is fully subscribed and paid up. The present issue will form a first mortgage on the Company's freehold land, buildings, and machinery, and be a floating charge on all the Company's other property. The Company recently obtained an official quotation on the Stock Exchange. A supply station has been erected, and is regularly supplying electricity. The number of lights being supplied by the Company on the 31st December, being 11,987, in addition to 1,114 lights ready for connection, 2,068 lights being wired, and 1,429 lights on order, a total of 16,598 lights, most of which the prospectus states should be in work within the next three months. The managing director in Spain, Senor don Pedroy, Pastor Landero, gives the above figures in his report dated January 1st.

**ELMORE'S FOREIGN AND COLONIAL PATENT COPPER DEPOSIT COMPANY (LIMITED).**—Notice is given that the transfer books of this Company will be closed from January 28th till February 4th, both days inclusive, for the purpose of paying a dividend.

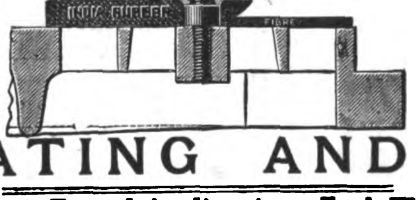
**CUBA SUBMARINE TELEGRAPH COMPANY.** — The Directors of this Company (after providing for the dividend on the Preference shares and placing £4,450 to the reserve fund) recommend a dividend on the ordinary shares at the rate of 8 per cent. per annum, tax free, carrying forward £715.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY.**—The traffic receipts of this Company for the week ending January 23, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £5,195.

**WESTERN UNION TELEGRAPH COMPANY.**—The numbers are announced of seven bonds of £200 each and six bonds of £100 each of this Company's Six per Cent. Sterling Loan, to be paid off on and after March 22nd next, at the office of Messrs. Morton, Rose, and Co., Bartholomew-lane, E.C.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 20th Sept. 1888.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue o get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

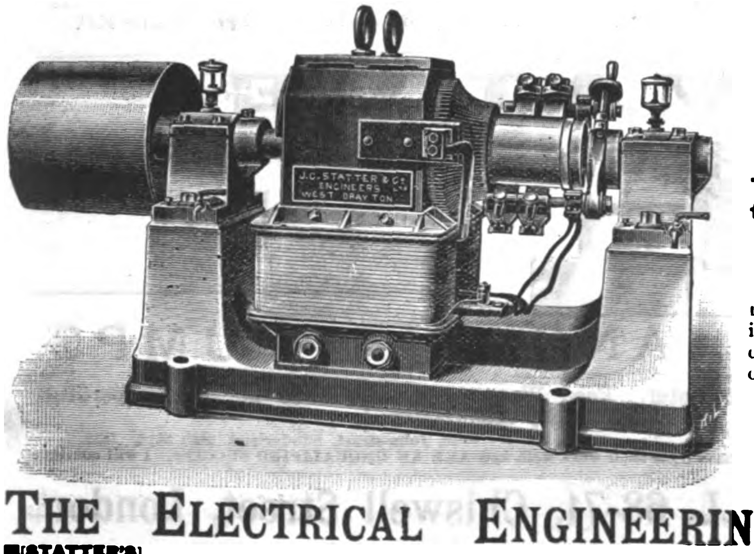
# IMPROVEMENTS IN DYNAMOS.



## STATTER-BRUNTON DYNAMO.

**The latest design in the market, made with all the advantages of the latest scientific knowledge and the highest mechanical skill.**

The woodcut represents our B TYPE DYNAMO. A most efficient machine, working noiselessly, and without sparking or overheating; is highly finished and well proportioned. The output is so rated in our Catalogue that the machines may be worked very much in excess of their stated full output for short periods.

**STOCK SIZES UP TO 77 KILOWATTS.**

**MACHINES BUILT TO 500 KILOWATTS.**

**THE ELECTRICAL ENGINEERING CORPORATION, LIMITED,**

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 664.—Vol. XXVI. FRIDAY, FEBRUARY 6, 1891. Price Fourpence.

## NOTES.

The application of electrical transmission of power to mining, which has engaged the attention of Messrs. Ll. B. Atkinson and Mr. C. W. Atkinson for several years, was the subject of a very interesting paper on Tuesday last at the Institution of Civil Engineers. To the paper itself we are debarred from alluding by the rules of the Institution; but having had some personal acquaintance with the matter, we take the opportunity of referring to it, now that the publication of the results has for the first time been made. A machine of a very crude form was used in a mine near Leeds for cutting coal in 1887, and was driven by rope transmission, with an efficiency probably not exceeding ten per cent. The manager thought otherwise; and it was not until a motor capable of delivering six horse-power was put to the work that he realised, by the continual breaking of the cutter-bars, how little power he had hitherto been using, and what an unfailing supply of energy could be provided by the use of electricity. The experimental machine to which the motor had to be fitted was a very primitive affair; but from the very first it was obvious that the coal-cutting by electricity would be a great success.

We cannot here explain the details of the work of "holing." Suffice it to say that it consists in undercutting the "face" of the coal walls. As done by hand, a cut some two or three, or even six, feet deep is made, and to allow room for the man to work while on his side, the width of the cut must be from 1ft. 6in. to 2ft. The cutting machine will cut 3ft. 6in., and has done 5ft., while the width of the cut is only about 6in., part of it being in the "parting" below the coal. The machine can be drawn along at about one yard per minute, and with a cut 3ft. 9in. deep 160 tons of coal can be won in a shift of eight hours, including stoppages for propping, &c. By the use of an electrical coal-cutting machine one man can easily replace four working by hand, and it is found that from 20 to 40 per cent. more large coal can be produced, partly on account of the narrowness of the cut, and partly by reason of the rapid and continuous progress of the work. The old cutter-bars, $2\frac{5}{8}$in. diameter, were continually broken, not unfrequently by having to take the whole weight of the machine when it left the rails. A $3\frac{1}{4}$in. bar is now used, and its design, together with the tools set in it, is a matter of considerable importance.

The subject contains many points of interest, and in many respects the teaching of experience has set aside theoretical ideas. The first motor was shunt-wound, in order to regulate the speed, and was provided with series coils for starting. It was naturally supposed that a series motor on such irregular work would run away when the load was removed. But it was soon found that the series winding offered important advantages, and as the friction increases at a much higher proportion than the speed, the theoretical difficulty disappears. The question of safety from explosions is also very interesting. The armature, as illustrated in a recent issue, is enclosed in an air-tight case. If an explosive mixture of air and gas were to penetrate into the casing, an explosion would, of course, take place, but if gas were to leak into the casing which previously contained air, it would quietly burn away before an explosive mixture could be formed, as it does in the ordinary miner's lamp. The gas, containing no little proportion of carbon would form $CO_2$, and when 14 per cent. of this is present any possible mixture of gas becomes absolutely inexplosive. It is satisfactory to learn that the experienced Government inspectors are quite satisfied on this point.

The little ceremony which took place outside the Mansion House on Tuesday may be taken as marking the close of the period of discussion and the commencement of actual work. Much as the cause of electric lighting has suffered in the past by ill-considered schemes, we are unable to regard the protracted labours and thirty-nine reports of the Streets Committee of the Commissioners of Sewers with quite the same degree of satisfaction as they themselves do, being of opinion that the lighting of even such an area as the City of London would not have been injuriously affected by a little more expedition. However, the final plunge once taken the City Commissioners in pleasing contrast to many other local authorities, seem disposed to afford the contractors every support, and the contractors in their turn may be trusted to carry out this important undertaking in a manner which shall reflect credit on all concerned. As to the financial success of the scheme, we see no reason to doubt it, provided ordinary prudence is observed, even though the City may not possess all the advantages from a central station engineer's point of view, as does the West End area, aptly termed by General Webber "the cream of the world." Apart from such considerations, however, the spirited policy of the Commissioners of Sewers may possibly cause those responsible for the lighting of the main streets and open spaces of our big cities to illuminate them in a style more befitting the end of the nineteenth century than is at present the case. The undertaking, therefore,

Digitized by Google

which was inaugurated on Tuesday has the good wishes of all who have the interests of electric-lighting at heart.

THE press visit to the Elmore Company's works, if it has not brought to light any information as to the commercial value of the copper, the cost of production, the probable price (for it is not even yet on the market), or the advantages which may be expected from Elmore wire, has at all events shown that some commencement has been made in manufacturing tubes, which are said to be used by brewers and calico-printers, and that the whole affair is something more than a mere catchpenny excuse for financial speculation and the promotion of companies. A process in which the density and mechanical qualities of the product depend on the elasticity of a few india-rubber bands, which press the burnisher against its work, must at present be considered unsatisfactory, while the only electrical feature that is offered is a 2 per cent. increase of conductivity, which is of little or no more importance than a 2 per cent. reduction of price. We hoped to have given some illustrations of the works, and we deferred the publication of the description, which will be found in another column, for this purpose; but the photographs sent to us proved to be quite unsuitable for reproduction.

AN example of the small importance with which a difference of 2 per cent. in conductivity is regarded in practice, is afforded by the correspondence elicited by our review of the excellent tables of Mr. BOULT. To test the question there raised, Mr. CONNOLLY has made measurements of the weight and resistance of a seven-stranded conductor, with a special short lay, and his results show that the divisor to give the resistance is 7·052, while the multiplier to give the weight is 7·142. There is an increase of conductivity amounting to ·743 per cent., while the weight is increased by 2.03 per cent. That the conductivity can never be proportional to the weight, is evident on a little consideration, though the exact calculation would be tedious, and might trench on Sir ROBERT BALL's favourite study of the mathematics of screws. If the strands were in perfect contact, the conductor might be considered as a solid piece of metal like clock-makers' pinion wire. It is obvious that the resistance and the weight of a foot of such wire when straight, must be less than a foot of the same when twisted to form an archimedian drill. The average weights given by Mr. CONNOLLY are of interest, and mount to an increase of 1 per cent., 1·843 per cent., and 2·44 per cent. for 7, 19, and 37 strands respectively. The difference between the increase of conductivity and the increase of weight in Mr. CONNOLLY's measurement is a little over $1\frac{1}{4}$ per cent., which is worth the consideration of those who point to 2 per cent. better conductivity as an important feature in a kind of wire which has been more talked about than used.

SINCE the days of ZAMBONI, a good dry battery has often been sought for, but the difficulties which arise from polarisation and local action have retarded any marked progress in this direction. The dry piles used by BOHNENBERGER and by FECHNER in connection with gold-leaf electroscopes were not intended to pass any current, but even for electrostatic purposes they were unreliable. Many attempts have been made of late years to construct batteries which, while not strictly dry, do not require continual attention and replenishing. Such a battery would be very useful for domestic bell-work, if it would save the great annoyance which is often occasioned by the sudden refusal of a battery to respond to the endeavours of a visitor to ring the front-door bell. Frequently the bell is at fault, since the complete silence is due rather to the fact that when the current falls below a certain point it fails to act at all, without passing through stages of faint ringing and mere trembling, corresponding to the gradual evaporation of the contents of the battery. Half-a-dozen dealers in electrical apparatus have dry batteries to offer, and among these the Gassner and Silvertown are well known, while the E.C.C. of the Electric Construction Corporation is one of the latest on the market, and we hear of others that are ready to be pushed. In another column we give an abstract of some tests of the Hellesen cell, from which a good deal more was demanded than need necessarily be expected from such a battery. Five ampere hours given in twenty-four hours through three ohms is a good output; but it is one which can hardly be expected from a dry cell. A really practical test would be to ring an electric bell once an hour for ten seconds at a time; if a battery can be made to do this for three years it would be very useful, especially if it were unaffected by climate and frost.

WE publish this week the results of an interesting study by Prof. NICHOLS, of the alternating electric arc between a ball and a point. As is well known, the sparking distance between two electrodes depends upon their size and shape, and if the terminals differ from each other in either of these respects, it is also found that the voltage needed to produce a spark depends upon the electrode which is made positive. Thus, if a ball and point are connected with some source of alternating potential it is possible to so adjust the distance between them that the arc only forms in one direction, in spite of the fact that the voltage is alternating. Some of the phenomena occurring under these circumstances are very curious; one of the most striking being the steady deflection produced on a high resistance galvanometer when shunted to the electrodes. The experiments seem conclusive as to the explanation of the phenomena, although the attempts made to utilise them for the purpose of alternate current measurement have as yet been unsuccessful. The method of investigation adopted, that of determining the instantaneous values of current and voltage for each moment of the cycle, is one which has been used with striking success by American electricians, and is the only satisfactory process where the more difficult phenomena caused by alternating currents have to be examined. Analytical and geometrical methods are only possible to the few, and the results yielded by them are too complex to be easily intelligible, besides being founded on doubtful assumptions regarding the sinuous character of the periodic changes in current and voltage.

COMPLAINTS have often been made that numerous patent agents in and near Chancery-lane exhibit conspicuous brass plates and other signs bearing the words "Patent Office." A

Digitized by Google

dozen or so of these impudent inscriptions, with which none of the first-class patent agents are connected, are obviously calculated to mislead the unwary. We have just had an experience of this kind ourselves, an arrangement having been made by one of our valued contributors to meet at the Patent Office someone who has a slight acquaintance with London. Although the latter was carefully warned, and the real building was described to him, he was fascinated by a staring brass plate, which he could not believe to be other than genuine, and so failed altogether to keep the appointment. On communicating with the Comptroller, and pointing out this clear case of deception and inconvenience, attended by the loss of time of two busy individuals, we are glad to learn that "the matter is now under consideration."

**Street Lighting in Paris.**—According to official returns, the public electric lighting of Paris comprises 297 arc lamps and 115 incandescent lamps.

**"The Manufacturer and Inventor."**—The new year's issue of this journal contains a remarkably well illustrated description of the City and South London Railway; also an illustrated supplement.

**Electrical Bills in Parliament.**—Among the Bills which have been formally brought in in the House of Commons are the London Central Railway, London Overhead Wires, and West London Tramway.

**Appointment.**—Mr. Bolton, assistant-superintendent of the Eastern Telegraph Company's London station, has been appointed the Company's superintendent at Liverpool in place of the late Mr. T. Moore.

**Chemical Society.**—The Chemical Society, having been founded in 1841, is now in the fiftieth year of its existence, and arrangements have been made to celebrate this important occurrence in the history of the Society on February 24th and 25th.

**Telephonic Development in Spain.**—Six telephone trunk lines are to be laid between Madrid and some of the most distant provincial capitals. It is also intended to connect all towns, including even the small ones, by telephone with the nearest telegraph station.

**Institution of Electrical Engineers.**—The annual general meeting of the students of the Institution will be held at the offices of the Institution, 28, Victoria-mansions, on Friday, the 13th inst., at 8 p.m., to hear the report of the committee on the last year's proceedings, and to elect a secretary and committee for the present year. All students are earnestly requested to attend.

**Technical Education in Lancashire.**—The Committee of the Lancashire County Council, in their report on technical education, recommend that the whole of the grant in aid, made under the Local Taxation (Customs and Excise) Act, 1890, should be appropriated for purposes of technical education, including agricultural and commercial instruction. The amount of the grant at the disposal of the county of Lancaster may be estimated at £39,000.

**The American Edison Company's Annual Report.**—The report shows a growing business of $10,000,000 per annum, with orders on hand for six months for 6,000 employés, the net earnings for the past year were 8 per cent. on the total stock, and the gross profits, allowing depreciation, $1,896,177. Plant sold shows an increase of 117 per cent. over the preceding year, and the output of the lamp works has increased 64 per cent., while its capacity has just been raised from 11,000 to 25,000 amps per day.

**Terrestrial Magnetism.**—M. Moureaux, of the St. Maur Observatory, is of opinion that he has found the cause of the remarkable deviation of the isogonic line when near Paris, a disturbance which extends across the Channel to the South Coast. He has found that centre line of the disturbance is coincident with a fault in the cretaceous strata to be found in north-west of France and the south-east of England, and he attributes the phenomenon to this fault, and not to the presence of iron ore deposits.

**Owens College, Manchester.**—The Council of this College will shortly nominate to one of the science scholarships offered by the Commissioners of the 1851 Exhibition. The scholarship is of the value of £150 per annum, and is tenable for two years. The scholar must devote his time to the prosecution of some special study with the view to advancing science or its applications to the industries of the country. Applications should be forwarded under cover to the Registrar not later than March 1st. For further details see our advertisement columns.

**Liverpool Overhead Railway.**—The Liverpool Overhead Railway is expected to be completed by the end of the present year. It extends along a dock line of nearly seven miles—that is, from Fort-road, Seaforth, at the north end of the Mersey Docks and Harbour Board estate, to the Harrington Dock at the south end. The railway will be a double line for passenger traffic only, and a traffic of 5,000,000 passengers is expected to be obtained during the first year's operations. Electricity, as has already been announced, is to be the motive power, and the particular system to be adopted is now under consideration.

**Edison Arc Light Dynamo.**—The Edison General Electric Company of America have recently brought out an arc light dynamo; the only feature of interest in it is the regulator which is attached directly to the dynamo base frame. It consists of a small flat piece of iron, pivoted near one pole piece, and a rack and pawl mechanism driven by a short belt from the dynamo shaft arranged to shift the brushes around the commutator in one direction or the other, as the governing armature is attracted more or less powerfully by the pole pieces. The field magnet is thus the controlling magnet of the regulator, as in the Hochhausen machine.

**Soldering Glass to Metal.**—At a recent meeting of the Société de Physique, M. Cailletet described a process of soldering glass and porcelain to metal. The glass tube to be soldered is first covered with a thin coating of platinum or silver, by treating it with a film of platinum chloride or silver nitrate and heating to dull red. A ring of copper is next electro-deposited on the platinised tube, which can then be soldered like any ordinary metallic tube. Solderings effected in this manner are said to be very strong. The top of a tube attached to M. Cailletet's apparatus for liquefying gases terminates in a soldered end, and successfully resists pressures of over 300 atmospheres.

**Electrical Standardising Institution.**—On Monday, February 16th, the first of what we believe will be a series of annual conversazioni, is to be given by Mr. and Mrs. Hammond at the Electrical Standardising, Testing, and Training Institution, Faraday House, Charing Cross-road. The Board of Control of this Institution consists of Lord Crawford, as Chairman, Lord Castletown, the Hon. Reginald Brougham, Mr. F. Francis Ince, Mr. W. O. Smith, and Mr. Hugh E. Harrison, who also acts as principal. It has just moved into the spacious premises built for it in Charing Cross-road, to which the appropriate name of Faraday House has been given.

**The Bradford Municipal Station.**—On Tuesday last week the Crompton-Howell battery ordered by the Corporation for the purpose of supplying current during the hours of light-load was formally switched on to the mains by Alderman Priestman. There has also been added to the plant at the works a Willans engine of 300 indicated horse-power, which drives a 5,000-light Siemens dynamo. The total available horse-power at the station is now about 800. Since the beginning of November three new feeding mains have been put down. When the works were opened, in September, 1889, there were 1,000 8 candle-power lamps connected. At the present moment 15,000 lamps are wired.

**The Cowles Process.**—The Cowles Electric, Smelting, and Aluminium Company, of Lockport, N.Y., have brought an action for infringement in the United States Circuit Court at Pittsburg, against the Pittsburg Reduction Company. Infringement is alleged on four patents, described as "improve-

Digitized by Google

ments in electric processes of smelting ore for the production of alloys, bronzes, and metallic compounds;" "an electric furnace and method of operating the same," and two improvements on the furnace. The Cowles Company claims that these patents, taken out in 1885 by Eugène and A. H. Cowles, are being used and operated by the Pittsburg Reduction Company for the purpose of making aluminium and alloys.

**Interchange of Electrical Statistics.**—A most important circular, says the *Electrical World* of New York, has recently been sent out by the Electrical and Allied Trades Section of the London Chamber of Commerce, dealing with the importance of a fuller interchange of ideas among the electrical engineers of all countries and a freer publication of the data obtained in the course of commercial work than is now possible. Of the enormous ultimate usefulness of such an organisation there can be no doubt. There has been far too much secrecy from purely commercial motives in the operation and administration of various electrical industries. In the long run, that course is best for all parties concerned that tends to improve the conditions under which electrical energy is supplied to the consumers.

**Personal.**—Mr. E. Garcke, formerly Manager and Secretary of the Brush Electrical Engineering Company (Limited), has been appointed Managing Director of that Company, and Mr. Broadhurst succeeds him as Secretary.——Mr. Wilson, late of the London Electric Supply Corporation, informs us that he has commenced business on his own account.——Mr. Orl V. Thomas, A.I.E.E., has resigned the position of Managing Electrical Engineer to the Taunton Electric Lighting Company, and has been appointed by the Crown agent for the Colonies to take charge of the installation at Singapore. The electrical staff of the company have presented Mr. Thomas with a photograph of themselves in a handsome oak frame.

**Expiry of Telephone Patents.**—The Bell patent expired on December 9, 1890, and the next important telephone patent to expire is that of Edison (No. 2,909 of 1877), which comes to an end on July 30th of the present year. This patent had originally 30 claims, the second of which ran as follows:—"In an instrument for transmitting electric impulses by sound, the combination with a diaphragm or tympan of an electric tension regulator for varying the resistance in a closed circuit, substantially as set forth." The life of the Hunnings' patent (No. 3,647 of 1878) terminates on September 16, 1892. This patent covers the use of a layer of finely powdered carbon, or some similar substance, between thin metallic diaphragms, as a telephonic transmitting device. The Blake transmitter patent expires on January 20, 1893. In this patent the electrodes are pressed against the vibrating diaphragm by means of adjustable springs. Finally, on February 1, 1893, Crossley's "compound microphone" patent expires.

**Regulation of Pressure.**—In a recent number of the *Elektrotechnische Zeitchrift*, C. Heim describes the following method of keeping the pressure at any point in a system of distribution perfectly constant under wide variations of load. A pressure wire is run from the switch-board to the point in question through the armature of a little electric motor, the magnets of which are separately excited from a source of constant E.M.F. The back E.M.F. of the motor will within certain limits be proportional to the current traversing it, and therefore to the loss of pressure on the line. The power developed by the motor is absorbed by a powerful spring. The angle of torsion of the spring is proportional to the power. Now the power being equal to the product of back E.M.F. into current the angle of torsion is a measure of the volts lost on the line. The movements of the spring can be utilised to vary the field resistance of the dynamo, the resistance of the feeder, the speed of the dynamo, or the number of cells in circuit, where accumulators are employed.

**Obituary.**—We regret to record the death at Liverpool on January 29th of Mr. Thomas Moore, at the age of 51. He entered the Secretary's office of the Eastern Telegraph Company in May, 1870, and at the end of 1872 became the Company's agent at Liverpool, being appointed, in December, 1882, superintendent on the opening of the station there. Mr. Moore's conscientious conduct and courteous manner gained him the esteem of all who were brought into contact with him.—On Monday, January 26th, Dr. Nicol August Otto, the inventor of the "Otto" gas engine, died at Cologne, from apoplexy, after a brief illness. Some 25 years ago Dr. Otto's attention was drawn to gas engines, and in connection with Mr. Eugène Langen he brought out an engine called Langen and Otto's atmospheric gas engine. Subsequently he invented the "Otto" engine, which found great favour, and enabled him to obtain large royalties. Dr. Otto was not brought up as an engineer, but had great mechanical talent and theoretical knowledge.

**The Westinghouse Record for 1890.**—During the year ending December 31, 1890, this Company turned out 217 alternators, having an aggregate capacity of nearly 16,000 kilowatts, or an average capacity of 73 kilowatts. This makes a grand total of 730 alternators, with a total capacity of 46,080 kilowatts, which have been turned out by the Company since its organisation in November, 1886. Last year the Company added another branch to its business, in the manufacture of electric street railway apparatus. The Company did not commence to despatch motors until July 1st. Since then 211 15 horse-power motors have left the shops for the equipment of forty electric railways. This makes an average shipment of over 35 motors per month. The Company also commenced last year the manufacture of alternating-current arc light apparatus. The first of these machines were despatched in January, 1890. Since that time the Company has despatched 107 alternating-current arc light dynamos, having an aggregate capacity of 5,680 2,000 candle-power lamps. There are now over 20,000 Shallenberger meters and more than 30,000 Westinghouse converters in use.

**Electric Traction in Guernsey.**—It will be seen by our advertisement columns that the Guernsey Railway are about to adopt electric traction. The line in question was constructed by the Guernsey Steam Tramway Company, and worked by them from June, 1879, till January, 1888, but having for some time previously been subjected to fierce competition by omnibuses, running was for a time suspended until the present Company took over the property and resumed working in December of that year. Though up to this steam locomotives have been employed, the Directors have from the first been looking for a cheaper means of propelling the cars, which usually run in trains of two or three, as the traffic demands, and they have decided to try the direct system of electric traction, the Local Government having given the necessary permission for the erection of the overhead wires at their meeting on January 28th. The line is 2 miles 65 chains long, single, with five crossing-places, practically level, but very crooked, fully 75 per cent. being deviations from the straight. One-half of the distance it runs on the public road, and the other part on the Company's own property. When the line had the whole of the traffic it did a heavy business, especially in the summer, when the island is full of visitors.

**Experiments in Magnetism.**—It has long been known, says Mr. A. E. Dolbear, in the *Electrical Engineer* of New York, that a common sewing needle will float if carefully placed upon a surface of water; also, that if the needle be magnetised it will assume a position in the magnetic meridian. Iron and steel filings will also float, and they can be sprinkled upon a liquid surface nearly as well as upon a solid. Let a strong U-magnet be brought near to the iron filings. They will at once arrange themselves in the well-known forms. If the magnet be removed the filings will retain their arrangement, and if it be in a vessel large enough to permit the rotation of the whole body the arrangement will swing into the magnetic meridian, thus showing that it constitutes a single magnet. Now bring gently near the floating magnet one pole of a bar magnet. If this be presented to one of the poles of the molecular magnet the whole body will rotate more or less. If, now, a magnetic pole be brought near to the middle of the arranged filings, some of the groups will be more or less disintegrated from the rest, and will rotate upon a vertical axis and turn quite round. The opposite pole presented will cause them to rotate back again. Great numbers of these can be seen to turn in this way when-

Digitized by Google

ever a pole is presented to them. This phenomenon is evidently precisely the same in character as that illustrated by Prof. Ewing with his small magnetic needles mounted upon pivots.

**Electricity and Natural Gas and the United States Customs Laws.**—The Treasury Department at Washington has recently given two decisions which have attracted a great deal of attention. A clerk of Customs on the Texas border asked the Department what tax should be levied on a certain electric company which was wiring its electricity across the Rio Grande into American territory. The Department has decided that, inasmuch as electricity is intangible, and cannot be measured, it can come in free. About the same time, an official at Buffalo inquired how he should treat the importation of a certain company in Buffalo which had made arrangements to bring natural gas across the Niagara River from Canada into the United States through an eight-inch pipe. In this case the Treasury Department has decided that natural gas is an unmanufactured product not otherwise provided for, and is therefore dutiable at the rate of 10 per cent. *ad valorem*. The manufactured product electricity can be brought into the United States free under this decision, but the unmanufactured natural gas, from which electricity could be produced, is taxable at the rate of 10 per cent. The Buffalo concern, if it desires to evade this 10 per cent tax, can, remarks the *Electrical Engineer* of New York, turn its gas fuel into an electric current on the Canadian side of the Niagara River, and carry it across the river through wires instead of pipes.

**The St. James's and Pall Mall Company.**—In another column, says the *Journal of Gas Lighting*, will be found a "Note" descriptive of the working results of the St. James's and Pall Mall Electric Lighting Company, to which the attention of gas engineers may be profitably directed. . . . In the first place, it is something for which we were hardly prepared, to observe that the whole of this particular business was done by meter, which shows that the electrical engineering of this London Company is far in advance of most others. . . . According to this statement, the St. James's Company can account for all their electrical output except 2½ per cent., which is an astonishingly high duty. It means that there is practically no loss through the mains and services, and that the consumers' meters are either very good, or very good for the Company, which is not precisely the same thing. Upon the former and more charitable interpretation, however, it appears that the St. James's electricians have nothing more to expect in the way of technical advancement; for a duty of 97·5 per cent. from the whole plant is practically perfection. It may be noticed that the Company charge 7d. per unit for their supply, which they say costs 1·8d. in the engine-room. On the face of it, one would suppose that the margin here shown ought to be sufficient to pay for administrative and capital charges. We have already admitted that if central station lighting is to pay anywhere in England, it will pay in the choice district occupied by this particular Company.

**Electrical Traction on the North Metropolitan System.**—At the general meeting on Wednesday of the North Metropolitan Tramways Company, Mr. George Richardson (the chairman) announced that the Board had thought it necessary to go to Parliament again in consequence of the action of the West Ham Board, to which they had applied for permission to use electricity. They were already using it, but the West Ham Board could at any time, by giving them 24 hours' notice, compel them to cease running. The Directors considered that this was unreasonable, and the County Council had given them power to run electricity for seven years without any restriction. They thought that the County Council had as much wisdom as the West Ham Corporation, and, therefore, they thought that the latter should be requested to give them the same privilege in this matter. If this body gave them the same power as the County Council had given them, they would not go on with the Bill; but otherwise they would ask the shareholders for power to continue their application. Replying to questions afterwards, the Chairman stated that the subject of electricity remained, so far as the Company was concerned, in just the same position as it did last year. The Electric Traction Company were running the same line at 4½d. a mile, including the driver, according to the contract. They had not much encouragement to go on with the use of electricity until they were perfectly satisfied that they could not be called upon at 24 hours' notice to give up its use. The Bill referred to was subsequently approved by the meeting.

**A Simple Temperature Correction for Copper Wire.**—Correcting the resistance of copper wire for temperature involves a formula which is somewhat too complicated for everyday calculations. The simple method described below may, therefore, be of use. It is due to Mr. Carl Hering, and appeared in the *Electrical Engineer* of New York. The Matthiessen standard of resistance of copper taken in calculating the table is that proposed by the Committee of the American Institute of Electrical Engineers, namely, 9·612 *legal* ohms for a wire of pure soft copper, one foot long and one mil in diameter, at 0deg. C., and called a "mil-foot." The temperatures have been calculated at which this mil-foot constant has regularly increasing values, the increase being 1 per cent. between each two successive values. In calculating the resistance $R_t$ of any copper wire of length L feet, diameter $d$ mils, and temperature $t$, one has only to use the formula $R_t = \frac{L}{d^2} K$, K being the mil-foot constant taken from the table for the temperature nearest to $t$:—

| Resistance per mil-foot in ohms (legal). | Temperature, Degrees Fahrenheit. | Temperature, Degrees Centigrade. |

**Inauguration of the Electric Lighting of the City.**—An interesting ceremony took place at the Mansion House on Tuesday last, when, at the invitation of the Directors of the Brush Electrical Engineering Company and the Laing, Wharton, and Down Construction Syndicate, the Lord Mayor inaugurated the lighting of the City by electricity by laying the foundation stone at the main junction which connects the conductors to be laid down by the two contracting companies in Walbrook. After the laying of the stone the company proceeded to luncheon at the Cannon-street Hotel. The Duke of Marlborough proposed the toast of "The Electric Lighting of the City of London," coupling with it the name of Mr. Preece. The following are a few particulars of the projected City stations:—The streets will be lighted by 400 arc lamps of 2,000 candle-power, and 1,000 incandescent lamps, absorbing from 100 to 200 watts per lamp. The cost of the illumination of the whole of the streets of the City will exceed £20,000 per annum. The site of the Brush generating station is on the south side of the river, and the mains will cross the river by the Southwark and Blackfriars Bridges. This station will ultimately have a capacity of 600 2,000 candle-power arc lamps and 120,000 8 candle-power incandescent lamps, this being for the supply of the central division. The generating station for the eastern division will be situated on the banks of the river between the Custom House and the Tower of London, and the Laing, Wharton, and Down Construction Syndicate have designed the plant to have an ultimate capacity of 600 2,000 candle-power arc lamps and 120,000 8 candle-power incandescent lamps. The Brush Company will employ Brush apparatus for street lighting and Mordey alternators and transformers for private lighting. The Laing, Wharton, and Down Construction Syndicate will employ Thomson-Houston apparatus throughout.

## THE HISTORICAL DEVELOPMENT OF THE INDUCTION COIL AND TRANSFORMER.*

BY DR. J. A. FLEMING, M.A.

(*Continued from page 397.*)

In Sturgeon's *Annals of Electricity*, Vol. I., p. 418, there is a mention of the meeting of the London Electrical Society held on August 5, 1837, when Sturgeon read a paper on "Secondary Electric Currents," illustrated by a powerful double-wire horse-shoe electro-magnet which had been presented to him by Prof. Callan, of the R.C. College, Maynooth. This paper or lecture stimulated several minds, and particularly that of Sturgeon himself. On page 470 of the *Annals*, Vol. I., we have another Paper by him on "An Experimental Investigation "of the Influence of Electrical Currents on Soft Iron as regards "the thickness of metal requisite for the full display of

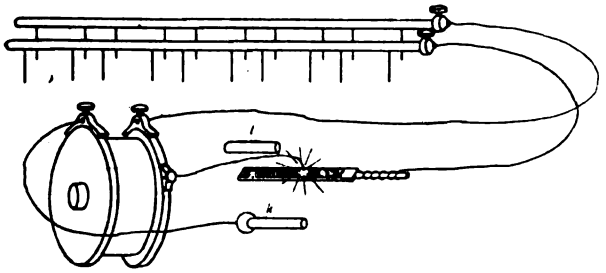

Fig. 3.—Sturgeon's Coil with Wooden Core.

"Magnetic Action, and how far these pieces of iron are "available for Practical Purposes." He constructed a double-wire helix on Callan's plan. He wound on a wooden bobbin a naked copper wire insulated with sealing-wax varnish. One wire was a copper bell wire, 260 feet long, forming the inner or lower coil; and the upper or outer coil was a thinner copper wire, 1,300 feet long. The end of the fine wire was soldered to one end of the thick wire, so that it made one continuous con-

ductor, wound all the same way on the bobbin. The reel, or bobbin, was of wood, two inches long between the cheeks. (*See* Fig. 3.) Strips of silk were interposed between the layers of wire. Hence, Sturgeon's coil was a short, wide coil, wound on a hollow wooden core, and not like Callan's magnet, which was long and thin. Sturgeon applied to his coils a break-and-make arrangement, consisting of a wire dipping in a mercury cup in one case and of a notched zinc disc in the other. (*See* Figs. 4 and 5.) The mercury cup-break was worked by a revolving cam and lever, and gave about 36 breaks per second when the cam was turned round by a winch. With the zinc disc he got 540 breaks per second. He put a *solid* iron core in the bobbin, and he was delighted to find that he got powerful shocks from the secondary circuit when the current from one or two cells was interrupted in the primary. He then made a very curious observation. He found that with the solid iron core the shock was much diminished in amount when the revolving contact-breaker went above a certain speed. After some trials he substituted a bundle of fine iron wires for the solid core, and he got very much better results. He draws attention to the fact that (*Annals*, Vol. I., p. 481,) Prof. G. H. Bachhoffner had tried a divided iron core about a fortnight before he had with one of Sturgeon's own coils, which he had lent him. Bachhoffner observed that a bundle of fine iron wires used

as a core in Sturgeon's coil gave far better shocks than when a solid iron bar was employed. We must therefore credit Bachhoffner with being the first to recognise the value of a divided iron core. W. Sturgeon noted that a rolled-up sheet of tinned iron put in as a core increased the shocking power in an extraordinary degree beyond that obtained when a solid core was used, and that with a bundle of fine iron wires as a core the shocks were more increased still. Sturgeon claimed that his coil was an advance on Callan's, and certainly when we regard the sketch of Sturgeon's first coil, we see that he gave to the appliance practically the general form which it has retained ever since. This coil of Sturgeon's was exhibited to the London Electrical Society in August, 1837.

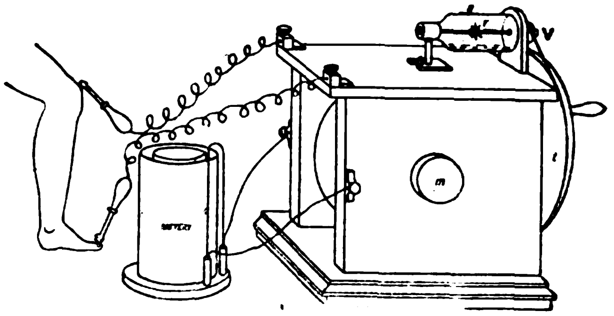

Fig. 6.—Clarke's Induction Coil

*m*, core of coil. *t*, driving wheel of contact breaker. V, driven pulley. *r*, star wheel breaking contact with mercury in vessel *x*.

We come next to another important Paper by Callan, dated September 11, 1837, printed in Vol. I., p. 491, of Sturgeon's *Annals of Electricity*: "On a Method of Connecting Electro-magnets so as to Combine their Electric Powers, and on the Application of Electro-magnetism to the Working of Machines."

Callan wound on each of two iron bars a couple of wires, first a copper wire one-twelfth of an inch in diameter put on in one layer, and second, a copper wire one-ninetieth of an inch in diameter, and 150ft. long wound over the first. Each wire was carefully insulated both from itself as well as from the iron and the other wire. It is clear from the description which follows that in making these two induction coils Callan did *not join* the end of the secondary wires to the end of the primaries, but left the secondary distinct and insulated from the

* All rights are reserved.

Digitized by Google

primary. He then *joined the primaries of these two induction coils in parallel* on a large galvanic cell, and the secondary coils he joined in series, and he obtained from the secondaries in series, a shock greatly in excess of that which he obtained from either of them separately. He points out that the secondaries must be so united that the electromotive forces in each are added and not opposed to each other, and he surmises that if a hundred such induction coils could be arranged with secondaries in series and primaries in parallel on a very large quantity battery that it would be possible to have a shock equal to that of 100,000 or 200,000 single cells.

On page 493 (*Annals*, Vol. 1) he says:—"In making "electro-magnets which are to be connected for the purpose "of obtaining increased electric intensity, care must be taken "*not to solder* the thin wire to the thick wire of the magnet, "but to leave both ends of the thin wires projecting."

In a note he recommends that for lecture purposes the thick wire coil and the thin wire coil should be wound on separate bobbins, the thick wire bobbin being made to slide inside the thin wire bobbin, and he says that such a pair of separate coils was given by him to Mr. Cottam, the secretary of the Manchester Mechanics Institute, during the lecture he gave there. Hence it is to Callan that we owe this simple piece of apparatus, now found in every physical laboratory, and it is to him that we are indebted for an induction coil having two separate wires, one thick and the other thin, used as an induction coil. Furthermore, he says that about four months before writing this Paper he coiled on a cylinder of wood (hollow) about 10 feet of covered copper wire, one-eighth of an inch in diameter, and over this 200ft. of very thin-covered wire, and an iron bar was put into the hollow of the bobbin. With 20 pairs of plates (*i.e.*, cells) on the primary, he got severe shocks even without the iron core, and when the core was put in he got a shock even on making the contact with the battery.

A little later in the first volume of Sturgeon's *Annals of Electricity* we reach a Paper by a Mr. E. M. Clarke, on an induction coil (*see* Fig. 6), for giving shocks with a single pair of plates. There is nothing more in this than a description of a Callan's or Sturgeon's coil. The secondary wire was one ninety-second of an inch in diameter, and the contact breaker was a Barker's wheel, or copper star, revolving so that the tips of its spokes just dipped in mercury in a bottle.

Some time previously Mr. Barker had invented this device for interrupting a current. Mr. E. M. Clarke was a philosophical instrument maker, having a shop in the Lowther Arcade, and his memory is also handed down to us as an improver of Pinii's magneto-electric machine. Mr. Sturgeon comments on Clarke's Paper, and, for appropriating without sufficient acknowledgment Mr. Barker's wheel and his own coil, he gives Mr. Clarke, of 11, Lowther-arcade, a dignified rebuke. Various improvers having been given the clue, took up the manufacture of induction coils. On page 205 of the *Annals of Electricity*, Vol. II., a Mr. Nesbit sends a description of a coil; it had a revolving rachet wheel as a contact breaker. A primary coil, consisting of 400ft. of thick wire, and a secondary of 1,700ft. of thin wire, and as a core a bundle of very fine iron wire. This description is dated February 10, 1838. This coil gave very severe shocks when the primary was excited, with one cell of half a square foot of active surface. Nesbit put oil on his break to reduce the noise and check the spark. Four days later, on February 14, 1838, Prof. G. H. Bachhoffner has a description of a coil which he made with two separate insulated copper wires and a core of insulated iron wires, and he notes that if the core of fine iron wires is enclosed in a tinplate tube it ceases to act as a divided core, and becomes no better than a solid core. He claims the original suggestion of using a divided iron core, and it appears from what he says that at first he used lengths of cotton-covered iron wires in a bundle as a core.

Bachhoffner refers also to a self-acting contact breaker which he put on one of his coils, and which he says was made by Mr. Neeve, of 11, Great St. Andrew's-street, Seven Dials, who made for him this magnetic contact breaker superior greatly to the spur wheel of Barlow or the notched disc of Sturgeon, both of which required to be actuated by hand.

(*To be continued.*)

## THE ELMORE PROCESS OF DEPOSITING COPPER.

We have already recorded the fact that a Press visit was made on Tuesday, January 27th, to the Elmore Company's works, near Leeds.

Towards 9 o'clock on Tuesday morning a goodly gathering of Press-men for both technical and non-technical journals, engineers, chemists, electricians, and other experts assembled at St. Pancras, and were conveyed in a special Pullman to Leeds, luncheon being served *en route*. With but little delay the tour of inspection began, the company being conducted by Mr. F. L. Rawson, Mr. Stepney Rawson, Mr. F. Elmore, and Mr. A. Elmore. The arrangements left something to be desired, the number of visitors being too great to permit of any one cicerone sufficing, while no systematic attempt to break up the crowd into several small parties was made. Mr. Rawson acted chiefly as spokesman when necessary, a duty that should rather have been performed by one of the Messrs. Elmore, on account of their more direct and intimate knowledge of the working of the process.

After regarding a heap of Chili bars which serve as the raw material, and which were stated somewhat hyperbolically to contain "97 per cent. of copper, and any amount of impurities," the visitors signed their names to guard against the possibility of the unauthorised intrusion of any hated rival in the shape of a copper manufacturer, left their watches to avoid risk of magnetisation, and passed to the melting shed. The installation is of a somewhat temporary character, the present output being small; the furnaces are of the usual type, and merely serve to run down the bars for the production of granulated copper. The time occupied in fusing each charge is about three hours. On this occasion this time had not fully elapsed, but in order to show the actual operation of granulating, the metal from one of the furnaces, though still somewhat sluggish, was run into a ladle, conveyed therein to the water tank, the slag skimmed off, and the copper allowed to trickle into the water.

The violence of the evolution of steam resulting from this operation was not very great, the chief cause of crackling and spurting being the presence of remaining particles of slag which cooled less evenly than the metal. A portion of the product was taken out of the tank for inspection; it was in the form of fairly even sized irregular fragments, mixed with a little slag.

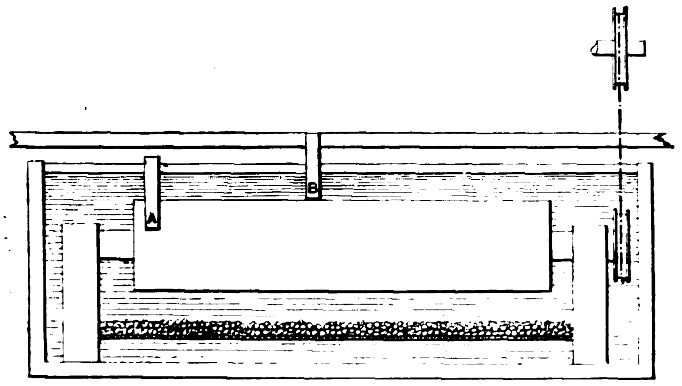
From the melting shed a move was made for the dynamo-room, the boiler-house, containing two boilers, each capable of developing 250 horse-power, being passed on the way. Here was a fairly-complete plant. Three Edison-Hopkinson dynamos, by Mather and Platt, and one Elwell-Parker dynamo not yet in position, constitute that part of the equipment at present. Three engines, each of 70 horse power, by Willans and Robinson, are in place, two driving Mather and Platt dynamos, and one with a dynamo on the same bedplate as itself. A place for a horizontal Fowler engine was being prepared to cope with the larger output that will be required when the second tank-shed is fitted. One of the Willans engines, coupled to a Mather and Platt dynamo, has the excellent record of having just completed a seven months' run, absolutely continuous; its companion is at present supplying all the power needed, which is only about 50 horse power. This yields a current of 750 amperes, at a pressure of 50 volts, the dynamo being run at 450 revolutions per minute; a larger nominal output is possible, but cannot be safely attained from these dynamos with continuous running, as they heat too much, the temperature rising steadily for about 24 hours after starting. The process being essentially one in which continuous running is necessary, even the possibility of injurious overheating must be carefully avoided.

The leads are copper bars, about $1\frac{1}{16}$ in diameter, and run to a switch-board in one corner of the room. By means of these, the current from any one of the dynamos or of the whole number can be distributed to the tank-sheds.

After inspecting the dynamo-room the company passed to the tank-shed, containing 60 tanks, part only of which are at present in use. Nothing particularly novel or striking had been seen up to this point, but in the tank-room the plant and methods of working characteristic of the process were open to inspection. The arrangements are of the simplest. Their nature can best

Digitized by Google

be gathered from the accompanying diagrammatic sketch; a wooden tank lined with bituminous material, at once insulating, adhesive, and unattacked by dilute acids, contains the solution of sulphate of copper. On the bottom of the tank is a copper tray, upon which is placed the granulated crude copper produced in the manner already described. A cast-iron mandrel, the ends of which are covered by a non-conducting composition to prevent deposition of copper taking place upon them, is supported in bearings, which at present are of wood, coated with bituminous material, but are in the future to be made of glass. The mandrel is rotated by a simple chain gear at the right-hand end. Contact is made with it by the brush, attached to a brass conducting strip (not shown) resting across the top of the tank. It is noteworthy that these brushes may be of the most feeble and ragged description without impairing the contact; it appears that so good a contact is secured by the continually renewed presence of freshly deposited copper actually *between* the end of the brush and the surface of the mandrel, that no precautions, such as would at first suggest themselves as desirable, if not necessary, are needful to ensure proper conduction. A metal burnisher, shod with agate, is pressed upon the surface of the revolving mandrel by means of india-rubber bands, the tension of which can be increased as the deposition proceeds. The amount of pressure used was somewhat quaintly stated to be 10lb. upon 9 sq. millimeters; such of our readers as are sticklers for uniformity of nomenclature can doubtless reduce these to more directly comparable units. The burnisher is carried by a bar at the back of the tank, which also carries the bur-



Depositing Tank.—A, Contact Brush; B, Travelling Burnisher.

nishers belonging to the whole series of tanks in line with it. This bar is given a longitudinal motion by a simple screw gear at one end, and thus causes all the burnishers to travel from end to end of the mandrels to which they respectively pertain; at the end of the stroke the motion of the bar is automatically reversed, and the burnisher returns in the same path. The result of this arrangement is as follows:—The crude copper forming the anode dissolves in the bath of sulphate of copper, which fills the tank (covering the whole of the mandrel and the agate end of the burnisher), and is deposited upon the cathode, that is to say, the revolving mandrel. As it is formed it is burnished by the agate burnisher, and rendered dense and coherent. The rate of revolution of the mandrel, the travel of the burnisher, and the width of the agate end of the latter, are so adjusted that the burnisher leaves no blank unburnished strip on the newly deposited copper, each burnished strip overlapping the one before it. By the use of this burnisher a comparatively high current density (15-20 amperes per sq. ft.) can be employed without producing weak crystalline copper. Those portions of the mandrel (the extreme ends) which do not come under the action of the burnisher, presented the rough irregular appearance usual when copper is deposited by currents of considerable density. It was also afterwards shown that copper of this description is vastly inferior in strength to that deposited with continual burnishing. The tanks are arranged in series, and require a pressure of something under one volt apiece. A tube ⅛in. thick takes about six days of 24 hours each to produce.

The chief portion of the work done in this shed is the production of copper tubes for use as such, but rollers for calico-printing and rams and propeller shafts are, or soon are to be, coated in a similar manner. In these cases the iron to be sheathed is first coppered in a cyanide bath, to ensure adhesion. When tubes are made, the point of importance is naturally not perfect adhesion to the mandrel, but merely close contact with its turned surface. Considerable difficulty has been experienced in making mandrels with a surface sufficiently smooth, the least irregularity being fatal to the formation of a satisfactory tube. Once a flaw or pimple has appeared, nothing will suffice to get rid of it; the tube in which it is must either be rejected altogether or at least the damaged portion cut-out. In our opinion this is a decided drawback. It cannot be easy, even if a thoroughly satisfactory surface be obtained at the beginning, to make certain of excluding all foreign particles, any one of which might start a roughness or flaw, and cause an imperfect tube to be turned out. This objectionable property has, however, one good side—as no flaw can be concealed by later layers, it follows that a tube of unexceptionable exterior must be sound throughout. Sundry sections that we saw confirmed this idea.

The only other matter in the tank-room needing comment is the question of residuals. The Chili bars used contain about 3oz. of silver and ¼oz. of gold per ton, and these are, of course, left with the insoluble portion of the anode. Up to the present time this, like the slag from the melting furnaces, has been allowed to collect until sufficient is available to make it worth while working it up. The Company intends carrying out this operation itself, though it would seem more natural to dispose of it to those who make the recovery of the precious metals their special business. Similarly the renewal of the electrolyte, which will doubtless be necessary from time to time as soluble impurities accumulate in it to an inconvenient extent, is to be effected with sulphate of copper made on the spot.

The tube formed in the manner described above is removed, mandrel and all, to the machine shop. As it adheres to the mandrel pretty closely, it is not at first sight a perfectly simple matter to separate them. The plan at present used consists in causing an arrangement of three small rollers to pass from end to end of the composite cylinder, whereby the sheath of copper is very slightly stretched, freeing it from the iron and allowing it to be drawn off without difficulty. The rough ends are then cut off, and the tube is complete. It is proposed in the future to vary this procedure by taking advantage of the greater coefficient of expansion of copper as compared with cast iron, and by heating the mandrel with its coating by means of steam to loosen the latter. This will leave the copper tube, on cooling again, of absolutely the same dimensions as the mandrel, and untouched by tool of any kind.

In the laboratory department, next visited, there are three distinct divisions, the first being a small laboratory for the routine work of analysing raw material, residuals, and electrolytes, and generally supervising the work of deposition. The second is the testing-room, where the product is subjected to mechanical tests. The third is the research laboratory, for improving the existing process and devising new methods. From this last visitors are, not without reason, rigorously excluded. With the exception of its noticeably neat and new air, and its short beam balance, unkindly exposed to the general atmosphere of the place, instead of being provided with a separate room, the first named presented little of interest. In the testing-room there was matter of more immediate moment. The miscellaneous gathering, including experts thoroughly familiar with every detail of mechanical testing, and non-technical journalists who had probably never seen a testing machine in their lives, flocked into the small room, and crowded it almost to suffocation. The first glance at the testing machine, which is a 30-ton one, makes one think for a moment that it is the well-known Wicksteed; but a second look dispels the illusion. It is certainly most curiously like, but the maker's name is Herriot not Buckton, and he hails from Glasgow instead of Leeds. Except that the water is supplied to the ram from a different pattern pump, and the gear for shifting the jockey-weight is not quite the same, it is practically identical with its forerunner. On this machine a test was made of a strip of copper cut from an unannealed cylinder

Digitized by Google

in the direction of its circumference, the curved piece thus obtained being of course first flattened out. With a crowd of gaping sightseers, with their noses almost in the clips, great nicety was not to be expected, but a rough test was performed, and gave a result of 20·8 tons per square inch, with an extension of 21 per cent. The high tensile strength, coupled with the considerable extension, is a feature in this copper which distinguishes it from that made by any other process with which we are acquainted. Nor is this the only remarkable property it possesses. It is stated that it can be worked cold to any extent without hardening; in consequence, it can be flanged or drawn into wire without undergoing any annealing process. Beautiful specimens of wire said to have been thus produced were exhibited. So much for its mechanical qualities. Of more direct interest to the electrician is its conductivity; on account of its method of production, more especially by reason of the low E.M.F. used, it is as nearly as possible pure. Arsenic, and such objectionable constituents, are entirely absent, and as a result its conductivity is extremely high, being stated as 102, when compared with Matthieson's standard, taken as 100. Since the metal used for the latter was also very pure electrotype copper, it seems tolerably certain that the higher conductivity must be attributed to the denser structure brought about by the continual burnishing during deposition.

The claims of the Elmore Company to have produced a copper in many ways unique can hardly be disputed. With the monetary aspect of the process we are indisposed to deal; that is a matter for the financial papers and the shareholders in the Company. Their directorate seems well satisfied, and is confident of underselling other makers of such articles as they manufacture, and at a very handsome profit to boot. The process is eminently rational, and certainly practicable, and the question of cost cannot be decided off hand.

It would be interesting to know on what particular claim the validity of the Elmore patents mainly rests. According to the account of the Company itself, and the evidence that could be gathered in a necessarily hasty visit like that we have just described, *the* point of all others is the burnishing of the copper with an agate style at the moment of deposition. But the process of burnishing copper with an agate style at the moment of its deposition has been known and practised for a decade. It must then be some special form of apparatus for executing the burnishing operation, or the combination of the burnishing with other prescribed modes of working, that are the essential means of protection of the Elmore process. However it may be protected it has been well wrought out, and its introduction marks a distinct epoch in the industrial history of what is *par excellence* the electrician's metal—copper.

## THE HELLESEN DRY BATTERY.

On the suggestion of Prof. Lommel, of the Physical Laboratory of the University of Munich, a series of experiments were conducted in November, 1889, by Herr Heinrich Krehbiel, Dr. Narr, and Dr. Doule, in order to obtain a comparison of the electrical qualities of six of the principal dry batteries in existence, viz., those of Hellesen, Bender, Thor, Gassner, Jenisch, and Wolfschmidt. A full report of these interesting experiments was published on August 1, 1890, in No. 31, Vol. II., of the *Elektrotechnische Zeitschrift* of Berlin, containing a detailed account of the following investigations :—

1. Change of E.M.F. on open circuit.

2. Variation of E.M.F. with temperature.

3. Determination of internal resistance.

4. Fall of E.M.F. on closed circuit, and subsequent recovery on open circuit under the following conditions:—(*a*) With an external resistance of 3 ohms furnishing a strong current; (*b*) with an external resistance of 50 ohms furnishing a weak current.

The E.M.F. was measured by an Edelmann's cylinder quadrant electrometer by comparison with a Latimer-Clark standard cell of 1·407 V (the coefficient for reducing the E.M.F. to the standard temperature being taken as 0·08 per degree Centigrade, as given by Helmholtz and Kittler). The measurement of resistances was effected by Kohlrausch's method, using alternate currents with the telephone introduced into the bridge. The Hellesen cells had the following dimensions: 8cm. square by 16cm. high (3¼in. square by 6¼in. high).

The mean original E.M.F. at 15°C., taken immediately after the receipt of the cells, was 1·415 V. The E.M.F. of each cell was tested periodically during 2½ months, and remained, with slight variations, practically constant, no current, however, being taken from them during that time. The E.M.F. was practically unaffected by change of temperature. The mean original internal resistance, taken immediately after the receipt of the cells, was 0·067 ohms; this resistance being lower than that of any of the other cells submitted for testing.

After these tests, one element of each kind was continually closed for 36 hours through an external resistance of three ohms, and periodically tested; the result obtained with Hellesen's cell being as follows:—At the beginning, 0·066 ohm; after four hours, 0·087 ohm; after 36 hours, 0·172 ohm. The experiments proved that all the elements increased somewhat in resistance when short circuited in this way for a long time.

To test the recuperative power possessed by these cells they were closed for 60 minutes through an external resistance of 50 ohms, after which time the circuit was opened, and the amount of recovery observed at intervals. This was repeated 25 times. After 60 minutes, the E.M.F. fell to two per cent., and after 24 hours recovery rose to 99·4 per cent. of the original value. All the elements, after 24 hours of open circuit, regained very nearly their original E.M.F. After closing continuously for 96 hours, through an external resistance of 50 ohms, the Hellesen cell fell 87·5 per cent, the Bender cell 86·9, and the Gassner 61·3. After 24 hours recovery, the E.M.F. was 94·1, 93·4, and 78 per cent. respectively. On closing the cells for 60 minutes through 50 ohms the Hellesen cell fell from 1·361 volt to 1·321, and after 24 hours' recovery gave 1·349 volt. The figures for the Bender cell are 1·359, 1·309, and 1·352 respectively; and for the Gassner 1·284, 1·170, and 1·285.

The investigation contains also the calculation of the ampere-hours from the values of current observed, and thus of the amount of work done by each element, the ampere-hours during the twenty-fifth hour being 96·7 per cent. of that furnished during the first hour of closed circuit.

The batteries when closed during 24 hours through an external resistance of 3 ohms gave the following aggregate ampere-hours:—Hellesen 5·0792, Bender 4·9898, Thor 3·4552, Gassner 2·6670. This investigation of the comparative efficiency of the above elements was concluded by the experiment of regenerating the partially-exhausted cells by a treatment similar to that of a secondary battery, *i.e.*, by sending a current from two Bunsen elements during two hours through the cells. The elements thus regenerated were again worked for five periods of closed circuit (each period of 30 minutes duration) through an external resistance of 3 ohms.

The Munich report contains the following conclusion, as the results of this exhaustive and carefully conducted series of experiments :—

"The most efficient elements, even for circuits of a small external resistance, are Hellesen's and Bender's elements. Hellesen's element excels Bender's by having somewhat less polarisation and much smaller internal resistance; it has, however, when exhausted by long working not quite so much recuperative power as Bender's.

"A similar relationship exists between Thor's and Gassner's element. In a circuit with a small external resistance Gassner's is less constant than Thor's, but the former has the advantage of more recuperative power, even after the E.M.F. has been reduced to a very small value.

Digitized by Google

"Jenisch's and Wolfschmidt's elements are in consequence of their very rapid polarisation only applicable when duration of closed circuit is very short."

The above experiments prove that dry elements are well adapted for many practical purposes, especially for telegraphic, telephonic, and similar services, and the considerable power of recovery possessed by such elements gives them a long duration of life. Besides the electrical advantages shown in the Munich report, there are various other advantages of a purely practical character possessed by such cells when compared with wet elements. The former are transported with far more facility, being always, and without any previous preparation, ready for use, and require no inspection or attention until they are completely exhausted. The Hellesen cell is made in England by Messrs. Siemens, Brothers & Co.

## ON THE INFLUENCE OF THE ELECTRIC SPARK ON THE DISCHARGE IN GASES.*

BY P. BACHMETJEW.

In our issue of January 2nd, p. 254, we had a brief note referring to the researches of M. P. Bachmetjew, on the influence of the electric spark on the electric discharge. The following is a more detailed account of these investigations:—

According to the investigations of A. Naccari, of Turin, it is the electric spark itself, and not its ultra violet rays, which alters the resistance of the surrounding medium through which an electrified body discharges itself. In particular it was observed that in air the discharge ceased if the sparking took place at a sufficient distance from the charged body, whilst if the air that had been in the neighbourhood of the spark was blown towards the charged body, a discharge immediately occurred. This, however, ceased to be the case as soon as the sparking was stopped.

The author is of opinion that one of the elementary gases of which air is composed undergoes, through the action of the electric spark, some chemical combination or allotropic modification, and that the resulting gas has a lower resistance than air. The gas produced must be of a somewhat unstable nature, so that it undergoes decomposition as soon as the sparks cease. But since no combinations of oxygen and nitrogen will satisfy the observed conditions, we must look for some allotropic modification of one of them. Ozone will immediately occur to the mind, but ozone at high temperatures resolves itself again into oxygen. The unknown conductor of electricity must, therefore, be a prior modification of oxygen, which may be called antozone.

The following consideration is also an argument in favour of the existence of antozone. In the well-known ozone tubes of Siemens, Babo, &c., in which oxygen is ozonised by means of a silent discharge, it is impossible to raise the proportion of ozone to over 40 per cent. This can only be explained on the supposition that the silent discharge produces from the oxygen both ozone and antozone simultaneously; a continuation of the discharge cannot increase the proportion of ozone, and when the discharge ceases the antozone being unstable breaks up again into oxygen. That the antozone actually behaves as has been supposed, can easily be made clear by the investigation of discharges in gases in which it cannot be produced.

The author compared the phenomena occurring at discharges in air, carbon dioxide, hydrogen, oxygen, and coal gas. The gases were enclosed in glass bell jars, at one end of which was placed a brass ellipsoid, to which was attached a copper wire. The end of the wire was connected to an electroscope, and two electrodes terminating in small copper spheres were introduced through the sides of the globe at a distance of one centimetre from the brass ellipsoid. Sparks from a Ruhmkorf coil were passed between the electrodes, whilst the ellipsoid was charged alternately in a positive and negative sense by a Holtz machine. The length of the spark between the electrodes was at first 1·5mm. and afterwards ·5mm. The experiments proved that the passage of the electric spark accelerates the discharge of electrically charged bodies, though to a degree varying according to the nature of the charge and the nature of the gas. Thus in air and oxygen the effect was more noticeable when the charge was negative, whilst the effect was greater with a positive charge in carbon dioxide, hydrogen, and coal gas. It would therefore also seem that under the influence of the spark hydrogen undergoes an allotropic modification which enables it to conduct negative electricity. The phenomena above mentioned are quite in accordance with the investigations on the electrification of conductors by red-hot bodies, published by Elster and Geitel.

## "THE DISTRIBUTION OF ELECTRICITY, WITH ESPECIAL REFERENCE TO THE CHELSEA SYSTEM."*

BY MAJOR-GENERAL C. E. WEBBER.

*(Concluded from page 399.)*

In February, 1885, Prof. George Forbes delivered certain Cantor Lectures before the Society of Arts. One of his objects was to assist electrical engineers in drawing out specifications, and selecting between systems. He then expressed his difficulty to be the probability that an expensive system proposed to-day would be superseded by a more economical one next year. He referred to the low-pressure multiple-arc distribution as being "enormously expensive," and the necessity with it of the generating station being in the centre of the district lighted, and also to the then absence of practical perfection of any system of high-pressure distribution.

Many of us can recall the able line of reasoning following which Prof. Forbes was led to select 1·5 square inches section of copper to the maximum current of 1,000 amperes, and his exhortation to engineers to withstand the pressure of financiers, and to tell them honestly what is the most economical thing to do; and that if a financier wants to lay out capital in a way to cause a waste of energy, the engineer ought to have nothing to do with it.

We are all agreed with what Prof. Forbes urged in February, 1885, namely:—

(1.) To use as large a number of points of alimentation and connection as we economically can.

(2.) That each of these points shall possess it own separate feeder.

(5.) The relative section of conductor at every point of a street to be the same as if every lamp had a separate wire going by the shortest street route to the central station.

But practice has shown us that we cannot, and need not, adhere always to two of his propositions, namely:—

(3.) That each distributing box must be nearer to the central station than any lamp fed from it.

(4.) That small groups of lamps should be fed from the distributing box by separate wires.

As regards the economical aspect of the case, practice shows, in any comparison, that, where a small section of copper in each conductor in the same line only is required, other conditions being alike, it is much cheaper to use insulation of the character of bituminous compound, in ducts, or "ways," of a small size and economical material, than to look for insulation to non-conducting supporting surfaces, with a large surrounding of air space subsisting in a subway of which the minimum first cost must be represented by a substantial figure.

It is in connection with large mains that the engineer who has first adopted the use of a dielectric material to surround his copper first turns his attention to bare copper, with a view to obtain a saving in construction. The size of these mains is controlled by the distance between the points of source of supply for a given demand in a given area.

Obviously, if these points can be placed nearer or further apart, according to what may be called the density of demand, there can be found a fairly definite limit to the size of the largest mains.

The positions of the feeding points in the areas between the points of source of supply are so much governed by conditions connected with the routes and communications of streets, that their theoretical frequency can rarely be maintained. In this respect only, then, apart from localisation of demand, need there be any uncertainty as to their size.

But where the source of supply is a large generating station, distributing at low pressure direct into a network of mains over a large area, say three-quarters of a mile a side, then I regard the adoption of a system of underground construction, such as that known as Mr. Crompton's, and used in part of Kensington, as unavoidable, owing to the necessity of using stems or feeders of large capacity. Indeed, such a system is the natural outcome of the conditions under which running machinery is the primary, and accumulation is the secondary, source of supply, with low-pressure distribution from one source.

On the other hand, when these conditions are reversed, the proximity of the sources of supply reduces the section of copper required for feeding the distributing network, and, as I have said, the cost of the underground works is by its simplification much reduced. Also, the position of the generating station is a matter of comparative indifference.

* Abstract of a Paper read before the Institution of Electrical Engineers, January 22, 1891.

Digitized by Google

Accumulators used in connection with any system which virtually distributes direct from the dynamo at low pressure can be regarded only in the light of auxiliaries, and in no sense as a main source of supply, or even as a stand-by. So far as I have observed, they act as little more than regulators, and are generally charged and discharged at the same time, and therefore not really fairly treated, and cannot be expected to have an average life.

The meeting will see that what is claimed for the Chelsea system in this respect is also possessed, under other circumstances of distribution, by any alternate-current high-pressure system, of which the transforming stations may be called sources of supply for low-pressure distribution.

I wish some one of my audience would, on an early occasion, favour us with a description of a well-designed converting station worked with transformers.

I am led at this stage to refer to the question of the candle-power of the lamp, to which supply companies refer when they give a popular estimate of the work they are doing. We hear of companies supplying 45,000 lamps, and others 100,000, and so on. Now the question is, What do they mean?

Not long ago a "glow lamp" meant a 16 or 17 candle-power lamp, consuming 60 watts per hour. If a calculation is based on such a unit, it is certainly not one that exaggerates the position of the suppliers.

Most engineers, if they thought in numbers of lamps at all, meant 10 to the nominal horse-power.

Now I wish this meeting to understand that from the first I have been one of the few that have steadfastly opposed the 60-watt lamp being the standard, for several reasons. Some five years ago, at a lecture I gave to the Society of Arts on the subject of the manufacture and use of incandescent lamps, I gave practical illustrations of the effect on the eye of the direct and reflected rays of various sizes of lamps—I think they were 5, 10, 17, and 30 candle-power—which showed that, so far as the appreciation of the eye is concerned, the naked filament only more and more paralysed the powers of vision, the larger the incandescent surface, and that the comparative effect on the sight of the reflected light of the various powers did not show proportionally to the disadvantage of the smaller ones.

In Chelsea we have from the first endeavoured, in the true interests, I believe, of an eventual large general consumption, to use the 8-candle lamp as our standard. In all circulars issued to the inhabitants and to customers we have consistently urged the use of that candle-power only, and the expediency, when more light is wanted at one point, of having rather two 8 candle-power than one 16 candle-power. We have pointed out over and over again that even in the largest houses, if there are no 16 candle-power lamps existent, their want is never felt, and that multiplication of 8 candle-power at each point is far the best way of illuminating.

At the risk of having the appearance of an endeavour to multiply numbers, all reports and publications of the Chelsea Company since 1885 have spoken of 8 to 10 candle-power lamps as the standard; and I believe that by degrees this policy—the wisdom of which cannot, I submit, be doubted—is having its effect, and that grumblers at the cost of the light who began, in spite of our remonstrances, by using 16 candle-power lamps, are gradually adopting eights. In the case of shops we have erred still more. We have overlooked the reasons for the successful rivalry of the Wenham and Sugg gas-burners, and instead of showing how electric light can be used more easily than other means for illuminating the tradesmen's wares, we have followed the lead with a poor imitation of gas, which obscures the vision of the passers-by, and makes it impossible to examine the details of the articles exposed. I have studied this question in our own and foreign streets, and am convinced that, in the long run, electric lighting will suffer, for the reason that, whatever its advocates may now say, a large number of tradespeople who are now employing it, after a trial of its use and cost, will return to that of gas.

The other day, in Paris, I was asked to meet a wiring contractor on the subject of fitting up for electric light a handsome ground-floor show-room which has large plate-glass windows. He had no other idea than to suspend half a dozen arc or "sunbeam" lamps from the ceiling, each consuming, at Paris prices, about 6d. an hour, which would have had the effect, doubtless, of lighting the footway brilliantly, and of attracting some attention from the casual passer-by, but also of preventing anything inside the show-room being efficiently inspected by the half-blinded beholder. I am no advocate for the other and equally unreasoning extreme of procedure by which light is wasted foolishly in frosting bulbs, or enclosing them in obscured and coloured globes.

In Chelsea we have come to the conclusion that out of five lamps installed in private houses two represent the maximum number in use at one time, and that we cannot expect that the gross earnings of each lamp installed will exceed 8s. 6d.; with the added fact that 70 is the average number of lights installed in private residences. This gives 28 in use at one time, at a cost of a little under £30 per annum at 8d. a unit. I know that this compares unfavourably with such districts as St. James's; but Chelsea is an average residential district, and St. James's is simply the cream of the world. I am sure that my friends who deal with the electric lighting of that part of London will understand that I am only drawing comparisons so as to give an idea of the demand in different kinds of districts. I see clearly that our experience heretofore in that direction shows us that the companies which supply current in what might be called the second-class districts have much to learn. We do not envy our brethren the fact that they have struck gold while we have only struck silver, and only ask them, in the interests of the industry, to make a good use of their luck.

In the districts in Chelsea and Kensington originally allotted to the Chelsea Company, the total number of houses in the streets and squares within the areas of supply is 1,258. This number includes all shops and residences, except those in quite the smallest streets. In this area the ultimate possible demand might be for 86,000 8 candle-power glow lamps installed, two-fifths of which—34,400—will probably be the maximum in use at one time. At present, of these houses, 252 take current, in which actually the equivalent of 20,000 8 candle-power lamps are installed, and of which the maximum of about 8,000 are in use at one time.

There are at present in the district four sources of supply, and 17 intermediate points where a constant pressure is maintained. The area within the parish of Chelsea which has been last added, and which contains no compulsory, or scheduled, streets, circumstanced as follows: The number of houses is approximately 4,400. The probable custom is likely for a long time to be confined to favoured spots, in which the ultimate demand will be 230 houses, having 18,400 lamps installed. The ultimate possible demand in this latter area cannot be estimated until a large portion of it is rebuilt.

To meet one-third of the total possible demand the central station will shortly contain seven 75 horse-power units of power to charge the five distant sources of supply and drive one transformer motor at each, with three 105 horse-power units to generate directly at low tension and charge the storage reserve in the station when required to do so.

Without going into financial details, it is easily seen how the gross earning capabilities of the station and surrounding system of supply and distribution in its present state will exceed £13,000 a year when one-third of the houses in the first area take current. How much of this may be expected to go to make up the net earnings is a matter I for the present may be allowed to forbear to suggest, as I am not engaged in compiling a company prospectus, but rather asking you to contemplate a sample of the industry under certain conditions from a scientific and commercial point of view.

In any system of distribution which employs—

(1.) Charging mains between the source of generation and the source of supply;

(2.) Stems, or feeding mains, between the source of supply and the points where the branches of the "tree" diverge;

(3.) Branches, or distributing mains, which start from these points of divergence and are connected with one another, or not, as the case may be.

Occasionally, in practice, instances are found in which the energy on its way to the consumers' lamps passes three times in one or other direction along the same route. Its first journey is caused by the need to convey it under comparatively high pressure to a point where it is to be converted to low pressure. The second is necessary in order that as uniform a pressure as possible may be obtained throughout a system. The third may arise out of the necessity to violate Prof. Forbes's rule, and supply backwards towards the centre of generation from the end of a stem, where the branches diverge.

This, be it observed, may occur with any system of conversion, if the converting plant is concentrated in stations. Anything which avoids it constitutes at first sight one important and very fascinating factor in favour of using alternate-current transformers in parallel series, as is being commonly done now in the case of many infant systems. The question is, must these systems be regarded as still in the stage "experimental," and must those who have laid them down be held to be wilfully shutting their eyes to their obligations under Provisional Orders—namely, to prepare to be able to supply every house and are they only desirous of picking up custom casually where it is surest and largest? Those undertakers who are now earning revenue with the service to theatres, hotels, clubs, and places of public resort, by such experimental means, would have still much to learn if, instead, they were dependent chiefly on domestic lighting.

It is only necessary to remind my hearers that if two points (occasionally called E.M.F. points) have a distributing main connecting them, there must be, if the conductors are of uniform section throughout, a depression which diagrammatically will be represented by a curve of a form which will vary according to the distribution of the load. To meet this condition of things the

Digitized by Google

Board of Trade, in the rules lately issued, prescribe that undertakers shall maintain a standard pressure which may be different for different portions of a distributing main, and shall declare to any consumer the constant pressure at which they propose to supply energy at his own terminals. Obviously, it is directed that, once declared, that pressure shall not be altered or departed from without authority, except within prescribed limits. These rules go further, however, and say that before using a distributing main the amount of such pressure (which, to meet an obvious condition, may be different for different portions of a main)—*i.e.*, the amount of those pressures—shall be determined, and given to the local authority.

Now, with great deference to the Board of Trade, our daily experience in Chelsea shows that this rule, professedly made as a help, may be used to bear very hardly on a supply company, if enforced to the letter. For instance, take a compulsory street, say with 30 houses along one frontage: we lay a main along it, calculating on a demand, say, from one-third of the houses, and an estimated maximum consumption in each. We don't know really how to proceed under the rule. At first, two houses, at irregular intervals, require current. What are we to declare to them and the local authority before letting them have it? Suppose we declare—what we know will be the case even if five or six houses require a supply—the same pressure throughout. Suddenly the owners of six more houses require current. This demand will at once cause a curve in the line of pressure; and, failing substitution of fresh figures in the declarations to some of the houses, near the centre of the street, which may be those that first came on—a change of intention that would not be easily allowed—or a substitution of a larger conductor, a state of dilemma is produced which neutralises the beneficent effect of this rule, designed for an almost completed system, and not a growing one.

The fifth part of the combination is the "use of underground conductors throughout, laid so that the cables can be drawn in and out, and renewed or repaired wherever necessary, without disturbing the ground."

This system, which the above description was intended to include, is the one known as the Callender-Webber system. Although an interested critic, I have not been lenient to it, and yet have no reason to go back on the reasons given last year for resorting to it. The network laid down in this system is situated along one or both sides of 41 streets, squares, and gardens of Chelsea and Kensington. The total length, in yards, of line of route followed is 9,520—nearly 5½ miles. The total length of insulated copper cable, varying between 61/12 and 19/15, in use for distribution of current is 27½ miles. Besides the above, there are 1½ miles of pilot wires, making a total of conductors of 29 miles. And the total weight of copper actually under the ground and in use is 51¼ tons.

Without the power of withdrawing and renewing or replacing cables, we should in Chelsea already have had a good deal of trouble and expense, having in several instances had to enlarge the mains. In this respect only—namely, that the conductors can be drawn in and out—is there any resemblance between this system and that referred to as Mr. Crompton's. But in the latter, to be able to do this, a box with a stone cover has to be placed over each point where the copper strip is supported on insulators.

But there are two limits to its applicability—one, where the probable demand is so scattered or sparse along any one route as not to justify so large an initial preparatory expenditure; the other, where the available space under the footways is insufficient. The former limit is at once appreciable when it is understood that the conduit complete, *without copper*, costs about £1 a yard, and in some cases more. The latter will be best understood by those engineers who have had occasion to carry on much excavation under the footways of our streets. I say the "footways," because, owing to the frequency of boxes necessary to give access to the insulating supports, the system, though feasible, is not well suited for a line under the roadway.

As regards the comparative cost of the two systems, it may be of practical assistance to let the meeting have the following result of my observations:—Generally speaking, if the section of copper in a pair of conductors is 1in. and under, then a main constructed with insulated cables in separate "ways" is cheapest—increasingly so with small conductors. Between 1in. and 1½in. the comparison varies according to circumstances. Over 1½in. of section, then uninsulated copper in conduits bears away the prize for economy. Actual experience in Chelsea enables me to give an example of the actual cost of a three-2-inch-way line laid in Lowndes-square.

Its length was 585 yards. The cost of supplying and laying the casing, including vestry charges and an allowance for engineering profit, was £189 17s., or at the rate of 6s. 6d. a yard.

For purposes of comparison, the cost of the surface boxes must be added to the above. Allowing draw-boxes for large angle changes of direction, and one service box for every two houses, we must add 2s. 3d. per yard, or a total of 8s. 9d. per yard.

On the three-wire system—for which provision is, I believe, always made in Mr. Crompton's mains—the three ways in the above example can receive two bitumen high-insulation cables of 61/12, having an external diameter of 1·71 of an inch, and one 61/15, with an external diameter of 1·40 of an inch.

The section of copper in these three cables is 1·335 of an inch, and their cost per yard *in situ* is 31s. per yard, giving a total cost of the completed line at less than £2 per yard. Supposing that the space between the stones of the footway and the cellars of the houses did permit of the introduction of culverts for the passage and insulation of bare copper—which, as it happens, they would not—even then the cost of the mains must be less per yard than if constructed on the Crompton system.

Recently, when in Paris, I was interested in having the opportunity of watching the laying down of mains by the Compagnie Popp, and by the Compagnie Edison. The former uses a cast-iron trough having a cover and means of jointing one trough to the other. These joints are by way of being water-tight. The cables are laid in three or four layers, three or four in each layer, and are separated from one another by slips of deal, with a deal board resting on the slips between each layer. These cables are laid in dry while the line is being made. Mons. Popp assured me that, when required, they can be easily drawn out, and others drawn in in their place; but this remains to be proved. The draw-boxes at the angles of streets, which have round iron covers in a square frame of the same material, are large, capacious inside, and consequently very convenient.

The mains of the Edison Compagnie, which I saw being laid, consisted of exceptionally large cables of uninsulated copper strand. They were being laid in concrete troughs of about 15in. in width and 10in. in depth. They were supported, without any possibility of being strained, on porcelain insulators, and the troughs covered in with stone flagging. These cables not only approached one another, but also the sides of the trough so closely, that I was startled at seeing the covers being laid on and the earth and footway made good. Being at a considerable depth—5 or 6 feet in many places—and having no access to the insulators, I cannot conceive how sufficient insulation can be attained or maintained. My impression was that the only obligation on the contractor was to get as many tons of copper under the ground as he could.

With low-tension distribution it seems evident that the size of the copper that may be eventually required cannot be easily estimated, and that, even if it could be so, it is not expedient to place underground quantities of copper which may have to lie partially idle for a long time to come. Hence the provision of sufficient capacity in culverts, ducts, or ways, into which copper can be introduced, either bare or insulated, as it is required, is a sound act of foresight.

But with high-tension distribution, accompanied by caution at the consumer's premises, the question can be regarded rather differently. For example, at Bath, where the "tree" system may be said to be in use, I have encountered the following conditions:—A stem of about 800 yards in length without any house connections on it; at the end of that two branches, traversing both sides in some cases, and one side in another, of two groups of streets and squares: in one case five streets, containing 150 residences, are passed along; in the other group six streets, containing 92 houses. Suppose that each house requires an average of 10 amperes at 100 volts, it will require half an ampere at 2,000 volts. The distributing mains in the first case will have to carry 75, and in the other less than 46 amperes, or cables of an average of 19/15 and 19/17 respectively. Now it is obvious that the least proportion of the cost of these mains is in the conductors themselves, and thus some such system as that for which the Messrs. Callender contracted with Mr. Massingham at Bath is probably the most economical. Such a main is described in Messrs. Callender's specification for what they call their "solid system," and, exclusive of the restoration of the surface, of which the cost varies according to its nature and the scale of charges of the local authority, would cost less than 9/- a yard run.

The line, once down and well laid, need, so far as one can see, never be disturbed, except by accident or injury, and a sufficiency of capacity for probable future demands is secured without heavy cost. For instance, the cost of a main with two insulated conductors of 7/16, laid in cast-iron troughs 3in. by 2in. internal section, and having 5/32 of an inch thickness of metal, the cables supported and kept apart by bridges of bituminous wood 2ft. apart, and the vacant space run in solid with bitumen, including taking up the paving, excavating, laying, filling in, and restoring the surface, is about 7s. a yard, including engineer's profit and superintendence—of course, if executed in lengths of not less than 500 yards.

In proportion to the number of cables and the section of copper, this cost is reduced, if four or more larger cables are laid. For instance, a main with a metal case containing four cables of 19/18 and four of 7/16, and having together ·23 of an inch in section of copper, can be laid and completed for about 15s. a yard.

I have had some of these lines tested for insulation resistance. In the case of one pair of 19/18 cables, with only two service

Digitized by Google

branches, on which the transformers were disconnected for the time in a length of 1,450 yards, which had been buried over six months, I found an actual resistance of over 100 megohms, or 60 megohms per mile. With the primaries of the two transformers in circuit, the result under the same conditions was 15 megohms, or 12·2 megohms per mile.

Another pair of similar cables, 1,500 yards in length, with seven transformers in circuit, gave only 3 megohms, or 2·55 megohms per mile.

As regards the question of depreciation, and cost of renewals and maintenance, we have a good deal still to learn. There are clearly four main classes, the conditions of which affect those prices, as well as that of capital cost, namely :—

(*a.*) Bare copper in the case of which the conductors and their means of insulation are inaccessible without excavation.

(*b.*) Bare copper where insulators are accessible, and the conductors can be drawn in and out without special excavation.

(*c.*) Insulated conductors which can be drawn in and out without excavation.

(*d.*) Insulated conductors which are fixed, and which, except at the boxes, are inaccessible throughout their length without excavating.

I may say that I have not yet seen a case of (*b*) class in its integrity—that is to say, without having in combination short lengths of (*c*).

Only lately the London Chamber of Commerce has rather startled us by issuing a circular in which it lays down the rule that depreciation for mains with "bare conductors insulated by means of glass, porcelain, or other such like imperishable materials," may be calculated at 1 per cent. ; while that on "all cables or other conductors covered with continuous insulation" should be calculated at 5 per cent. Now, if that body had accompanied their statement by a few words of explanation as to whether the calculation is to be on the cost only of copper insulated in the one way or the other, we might have thought it worth while to discuss with them the question, even though it is quite outside their province to lay down any such laws. But as we are left to suppose that the cost of the whole structure of the main may be included in the figure from which the percentages are to be deducted, I really do not think it worth while to take up the time of the meeting beyond drawing marked attention to the document, which probably several present have seen, in the hope that some speaker, struck with the adventurous nature of the statement, as I have been, may be led to give an opinion on it in the discussion which I hope may follow.

## ELECTRICAL UNITS OF THE PRESENT AND FUTURE.

The following extract from an address delivered to the New York Electric Club on December 18th, by Prof. F. B. Crocker, may be of interest :—

The more exact requirements of advanced work at first only required definite standards. Therefore the standard yard and the standard quart were adopted, but they were arbitrary. Some person decided what they should be, and they were carefully made and deposited in the national archives, and exact copies of those were made and sent around to various points, and they became in some cases the legal standards.

Self-induction is somewhat unfamilar, nevertheless, it is becoming important. It happens that there are several ways of defining self-induction, but the best way, I think, is to consider it as a counter electromotive force, and to define the unit self-induction to say that it gives a unit change of current in a unit time. The ordinary way, however, for deriving this unit is to multiply resistance by time. That seems to be an odd way to get it, but what it means is this: that self-induction is the apparent increase in resistance that we get when we try to pass a current through a circuit.

I would like to point out the fact that we have "absolute units" and "practical units," so called. I put both of these in quotation marks. Absolute units are not absolute, they are based on an arbitrary dimension of the earth incorrectly measured. Practical units, in the same way, are not practical, because we have one, the farad, that is 1,000 times greater than the greatest practical capacity in existence. Therefore, I maintain that we must have a third system of units, and that is the "working" units. You could call them "commercial," but the objection to that is that they are equally used in the laboratory as in commercial work. We use a microfarad in the laboratory the same as in the office of a telephone or cable company. Therefore, they are not, strictly speaking, commercial, but they are *working* in both cases. Sometimes the working units agree with the practical and sometimes they do not. The ampere, coulomb, and volt are the same, although in telegraphy we use the milliampere. Then we come to the ohm. That is, the ohm is right for most practical work, but for insulation tests we have to use a megohm. Nobody thinks of giving insulation tests except in megohms. Therefore for that class of work, the working unit is the megohm and not what is called the practical unit. When we come to the microfarad, there is no question. The practical unit ceases entirely to be practical, and we have to adopt the working unit, which is almost infinitely different. The watt is a convenient unit for a great many purposes, but when we use it for large work we use the kilowatt, which, by the way, is a good way of rating dynamo, because it is fairly near a horse-power.

Then we come down to the last of all—the henry, the new member of the family, and it is a question whether the working unit will be a henry or a millihenry. I did think of reducing the value of the henry to one-thousandth of its value ; but it would have been a mistake, for the reason that, instead of having its value one second multiplied by one ohm, we would have its value a second multiplied by a thousandth of an ohm or a hundredth of an ohm. That would be destroying the simplicity and the harmony of this system—a feature which it certainly does possess. Every one of these units is derived from every other one in the simple ratio of one to one, and in no case is there any complex relationship of a thousandth or ten-thousandth or anything of that sort. You see that the coulomb is an ampere multiplied by a second, a volt is one ampere multiplied by an ohm, a farad is a coulomb divided by a volt. A joule is a volt multiplied by a coulomb, and a henry is a second multiplied by an ohm ; and to make any one of them variant would, I think, be a mistake, particularly as it would have been the only exception to the harmony of the system.

Fortunately, the henry approximates a practical value. For example, a large Edison dynamo shunt wound will run up to one or more hundred henrys. A telephone magnet will be between one-hundredth and one-tenth of a henry. We could not expect that to be a very large value. An ordinary relay is several henrys in value. A large induction coil is often 1,000 or more henrys in value. Therefore, there is nothing preposterously small or large about the henry. It is about right.

In regard to future units, which the requirements of advanced work will soon necessitate, we need a unit of the strength of a magnetic field. We can express it as so many lines of force to the square centimetre, &c., but that is a very clumsy way. If we simply called it one Franklin, it would be very preferable to a long sentence.

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**FRIDAY, February 6th.**

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse: "Some Applications of Photography," by Lord RAYLEIGH, F.R.S.

**MONDAY, February 9th.**

SOCIETY OF ARTS.

*8 p.m.* Cantor Lecture II. 3. "The Construction and Capabilities of Musical Instruments," by A. J. HIPKINS, F.S.A.

**TUESDAY, February 10th.**

INSTITUTION OF CIVIL ENGINEERS.

*8 p.m.* Ordinary Meeting. Paper to be discussed: "Electric Mining-Machinery," by LLEWELYN B., and CLAUDE W. ATKINSON, A.M.M.I.C.E.

**WEDNESDAY, February 11th.**

SOCIETY OF ARTS.

*8 p.m.* Ordinary Meeting. Paper to be read: "The Proposed Irish Channel Tunnel," by Sir ROPER LETHBRIDGE, M.P.

**THURSDAY, February 12th.**

INSTITUTION OF ELECTRICAL ENGINEERS.

*8 p.m.* Ordinary Meeting. Paper to be discussed: "The Distribution of Electricity with Especial Reference to the Chelsea System," by Major-Gen. WEBBER, R.E.

**FRIDAY, February 13th.**

PHYSICAL SOCIETY.

*5 p.m.* Annual General Meeting, after which the following Papers will be read or discussed: 1. "Photo-Electricity," by Prof. MINCHIN. 2. "The Change in the Absorption Spectrum of Cobalt Glass produced by Heat," by Sir JOHN CONROY, Bart.

INSTITUTION OF CIVIL ENGINEERS.

*7.30 p.m.* Students' Meeting. Paper to be read: "The Cleaning and Deepening of Rivers and Canals by means of the Transporting-power of Water," by W. HERBERT WHEELER, S.I.C.E.

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse: "Some Results of Recent Eclipse Expeditions," by Prof. A. SCHUSTER, F.R.S.

**SATURDAY, February, 14th.**

ROYAL INSTITUTION.

*3 p.m.* Afternoon Lecture: "The Forces of Cohesion," by LORD RAYLEIGH, F.R.S.

# The Electrician.

**Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny**
**Editorial, Publishing, and Printing Offices:**
**SALISBURY COURT, FLEET ST., LONDON, E.C.**
*Telephone No.* 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

*All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher,* "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co." All other letters to be addressed to the Editor.*

*All letters intended for insertion in* "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

*New Volumes of* "THE ELECTRICIAN" *commence in May and November.*

## SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

| | 3 months. s. d. | 6 months. s. d. | 12 months. s. d. |
|---|---|---|---|
| For the United Kingdom | 5 0 | 10 0 | 19 6 |
| For Foreign Parts and Colonies:— Within Postal Union | 6 6 | 12 6 | 24 0 |
| Aden Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar | 7 6 | 14 6 | 28 0 |

## TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.*
**It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

*Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xvii.) are accepted up to 4 p.m. on Thursday.*

## TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

## "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

*Early in each year is issued* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consisted of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

*The 1891 Edition is now actively preparing, and Subscription and Advertisement Orders, New Names, Corrections, &c., can be received.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

***All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of* "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.***

## STEEL-PLATE PORTRAITS

*Of W. H. Preece, F.R.S.; Michael Faraday; Sir John Pender, K.C.M.G.; Sir William Thomson, F.R.S. (Past-President of the Institution of Electrical Engineers); C. H. B. Patey, C.B. (Late Secretary of Telegraphs, G.P.O.); Dr. John Hopkinson, F.R.S. (Past-President of the Institution of Electrical Engineers); Dr. Oliver J. Lodge, F.R.S., and Prof. William Crookes, F.R.S. (President of the Institution of Electrical Engineers), have been issued as Supplements to* "THE ELECTRICIAN." *A few Copies of these admirably-executed Steel Engravings can be supplied, price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, post free, 4s. 6d.*

## MORE BOARD OF TRADE RULES.

The legislation of 1882 stifled the beginnings of electric lighting by the imposition of conditions which discouraged its most energetic advocates, and it would seem that an additional load of statutory embarrassments is likely to be added to those which already encumber its progress, in a way which must delight its opponents. We refer to the new "Model Clauses for the protection of Telephones," printed in our last week's issue. The first Electric Lighting Act was a unique measure, inasmuch as it was intended to care for an industry which at that time had hardly passed beyond the stage of experiment, and about which no practical knowledge whatever had been gained, and little evidence could be procured, except such learned generalities as form the stock-in-trade of eminent scientific witnesses. Fortunately for the community, originality is not common among those who frame our laws, and it is undoubtedly to the credit of those who drew up the Act in question that so few errors were made in its provisions. After the continual mention of the local authorities, who were then, as now, so favoured by the Board of Trade, no references are so common in the 1882 Act as those which cite the Gasworks Clauses Act, and it is evident that those who were responsible for the new Bill adopted the common practice of following as closely as possible the steps of those who, if they did not know more about their work than their copyists, had at least produced something which, after the usual trimming and polishing, had for many years been established as an Act of Parliament.

Digitized by Google

When railways were in their infancy STEPHENSON made his experiments, locomotives were built, lines were laid and trains were run without troubling anybody in Whitehall. Some fourteen or fifteen years elapsed before it was found necessary to extend the powers of the Board of Trade to railway matters. The old Railway Acts were closely modelled on the Canal Acts, and so little were future developments realised, that it was assumed that anybody who wished to do so could run their own locomotives and coaches on the new lines. The only difficulty indeed, and one which was carefully noticed by the Great Western Railway, was, that any troublesome person who desired to avail himself of the privileges accorded by the law would have to commit trespass before he could place his engine on the rails. Gas lighting, again, had become firmly established before the Board of Trade had to undertake any supervision, though the regulations that were found to be necessary were of a very simple character, and did not develop in a gradual manner as in railway work. The engineering regulations of the Board of Trade are to this day of a very permissive nature. Whether it was a good thing for railway enterprise and for public safety or no, the fact remains that half a century ago no zealous official, with the doubtful assistance of a nonchalant council of laymen, drew up a set of regulations for the protection of public safety, and ordered continuous brakes to be fitted to all trains, automatic couplings to be provided forthwith, and every line to be immediately worked on the block system. Such an official could have adduced with but little difficulty excellent reasons for such simple and valuable proposals; but fifty years have passed, and while the able advisers to the Board of Trade know well enough the importance of such appliances, they admit that the railway engineers have a right to be heard, and they respect their statements, and acknowledge the difficulties which exist.

Bearing these antecedent facts in mind, there was nothing ominous in Section 6 of the Electric Lighting Act, which enacts that the undertakers shall be subject to such regulations and conditions as may be inserted in any licence, order, or special Act with regard to (*a*) the limits and conditions of a compulsory or permissive supply, (*b*) a regular and efficient supply, (*c*) securing the safety of the public, (*d*) the limitation of prices, (*e*) inspection, (*f*) enforcement of duties, and, lastly, a convenient and elastic section (*g*) to cover any unforeseen or forgotten point, "generally with regard to any other matters in connection with the undertakings." The first of these has as yet given rise to no friction. In respect of (*b*) and (*c*), the Board has done its best, or perhaps its worst. As to prices, a healthy competition has rendered interference unnecessary in London. Inspection, we have still to experience, and little is known about it beyond the ridiculous salaries offered in London and Liverpool. Of enforcement of duties it is as yet too soon to speak. But apparently one of the "other matters" is now to claim the attention of those who are engaged in the supply of electrical energy. We refer to the interference of telephonic service by induction or leakage. Having secured the safety of the British public, and being satisfied that they have done their best to render overhead wires innocuous by coating them with a feeble and clumsy covering of vulcanised india-rubber (forgetting mechanical protection in their zeal for insulation), the Board of Trade have turned their attention to fostering a business which another Government department recently declined to purchase. Can it be that the Post Office did not care to take over the telephones while they were in so defenceless a condition, and preferred to wait until the Board of Trade have shielded them from insidious induction, and guarded them from those vagrant currents that leak out through faulty insulation and creep home the wrong way through earth connections that ought not to exist?

We cannot, on the present occasion, go into the legal question of the creation of a property in the ground as a conductor. From the earliest days of telegraphy everyone has considered that he has a right to earth a line and to use the soil as a return circuit, or to bring his line to zero potential, or to use the earth as a common reservoir of electricity according to his ideas of the matter; and the cases of interference, until extended use was made of the telephone, were more interesting than annoying. But to-day there is scarcely a telephone line in London on which one is not disturbed by the wail of a Wheatstone or the tattoo of a tape instrument, and the Company is well aware that these and other annoyances diminish the value of the service which they provide by at least one-half. They have more subscribers than they can properly deal with, and they are well advised in endeavouring to improve their service rather than reduce their rentals. We should, indeed, welcome any measure that would render the use of the telephone less exasperating than it is to-day; but it seems to us most unreasonable to attempt to restrict the use of other electric lines, as though they were inherently inimical to the telephone; and the one thing suggesting that the proposed regulations are not inspired by the Post Office is that, where that body has undertaken telephony, it has from the first adopted the proper measure of looping all wires and providing a metallic circuit. We understand that the Telephone Company is looping the trunk mains which connect the various Metropolitan exchanges; but finds great difficulties in the way of carrying this out for subscribers' wires. If statutory powers to lay these under the street will solve the difficulty, the objection at present urged against metallic circuits, viz., the outcry which would be raised if the present overhead wires were doubled, would disappear. A sensitive instrument like a telephone—the most sensitive instrument, in fact, that is at the disposal of ordinary mortals (Mr. BOYS being excepted)—must be used with special precautions. The electric supply companies have their Acts of Parliament; and what have these been obtained for, at so great expense, if not to enable them to do certain things at a profit, for the eventual good of the public, which they could not otherwise have done? Railway companies have their Acts, and having their Acts no neighbour can complain that they rattle and roar. It is partly because they rattle and roar that Acts are necessary, but they must not commit any needless nuisance such as the establishment of gas works. So, too, an electric supply company must not pollute the air with smoke. If it were a fact that a telephone with a metallic circuit was liable to be disturbed by induction or leakage, there would then be more justice in their demand for the peaceable and quiet enjoyment of their property. But the present proposals relate also to future telephone wires, which may some day be laid, and it is assumed that there is some property in the future in a district as yet uncivilised by telephone or electric supply. The rights of the first comer are comparatively easy to settle, but this is indeed a wide demand. The gas companies having their Acts lay their mains, and do not mind if a few hundred thousand feet leak away into the surrounding earth. But anyone who afterwards builds a conduit in the reeking soil has to make it gas tight if he can, and ventilate if he may, and take the consequences, whether he likes them or not, when an explosion occurs. Imagine the feelings of a gas company (the feelings of a gas company!) if they were told that they must so reconstruct their existing mains, and so lay all new ones, that any person who shall hereafter build a conduit within a reasonable dis-

Digitized by Google

tance shall have so little trouble with any leakage of their gas that he need not go to the expense of ventilating it; and to make the parallel more complete, it must be imagined that the conduit builder has as yet no statutory powers whatever.

Electric supply companies have been sorely tried in the past with grandmotherly rules. First of all the protection of the lines of the POSTMASTER-GENERAL, and then the safety of the public, have been the occasion of most stringent regulations, and now a new trouble, arising from the incomplete character of other people's work rather than from any fault in their own, threatens their operations. Is it too much to hope that this latest difficulty may be speedily adjusted by mutual concessions without troubling the Board of Trade for any more of the regulations of which they have of late given us so many specimens. This powerful Government Department has taken up a position which may almost be described as hostile, and the frequent rebuffs encountered by commercial men in their dealings with the Board of Trade only tend to widen the breach which at present unfortunately exists.

## REVIEW.

**Electric Light Installations and the Management of Accumulators.** Sir DAVID SALOMONS, Bart. Sixth Edition. (Whittaker and Co.)

This book has grown considerably since its first issue, and, moreover, it has been found advisable to give it a more comprehensive title. The impression produced on reading the section dealing with accumulators is not unlike that which an uninitiated reader receives on perusing a book on medicine. It gives the idea that an accumulator can never be anything but a mass of diseased plates, although the author gives assurance that a properly managed battery ought to give no trouble at all. From a practical point of view the work is an excellent book of reference for persons engaged in the management of accumulators and installations generally, and teems with useful hints, suggestions, and figures for every-day working. In the chapter on governing are described several highly-ingenious devices of the author's for rendering the action of switches and apparatus automatic. A short history of the Broomhill installation is highly interesting and instructive.

Looked at from a scientific point of view, the book does not show to such advantage. There are several mistakes and misleading statements, which must be eliminated and corrected before anything like perfection is reached. For instance, on the first page, before the introduction, we find the following interesting statement:—

Watt = volt × ampere = measure of *force* or energy.

This is new to us. The author treats us also to a new expression for the chemical action which takes place in charging a secondary cell. It runs as follows:—

| | Positive. | Electrolyte. | Negative. |
|---|---|---|---|
| First stage | $PbSO_4$ | $H_2SO_4 + H_2O$ | PbO |
| Second stage | PbO | $H_2SO_4 + H_2O$ | PbO |
| Third stage | $PbO_4$ | $H_2SO_4 + H_2O$ | Pb |

In the second stage three O's and one S are missing, one O re-appears in the third stage, but the remaining O's and the S are apparently resolved into the primordial ether. On page 152 the author depreciates the insulating powers of ebonite; we presume this material is only good enough for bridges, condenser keys, and such-like rough apparatus. Again, we are told in the section relating to arc lamps that "an increased current greatly increases the light, *the proportion of current to light not being direct, as in the case of glow-lamps.*" Now, Sir David knows better than this, as is shown by a remark which occurs in a later chapter. The book has a distinct and extended sphere of usefulness, and, when still further revised and corrected, will be a valuable addition to electrical literature.

## THE MAGNETISATION OF IRON: PHENOMENA OCCURRING AT A RED HEAT.[1]

In the interim report presented last year it was stated that this Committee, which was appointed some time ago to inquire into the various molecular changes connected with the magnetisation of iron, proposed to confine itself, as we believe was the original intention on the appointment of the Committee, to those remarkable physical phenomena which are found to occur in iron and steel, about the temperature of a red heat when iron ceases to be a magnetic metal.

The suddenness with which iron loses its magnetic susceptibility at a red heat has often been noticed by different observers. Prof. Rowland[2] was the first to point out that for small magnetising forces, the susceptibility of iron increases as the temperature rises, reaches a maximum at a red heat, and then falls suddenly to zero, but that the susceptibility diminishes as the temperature rises when large magnetising forces are used. Bauer[3] subsequently established the same fact. Later, one of us (H. F. Newall[4]) has experimented with small spheres of iron and steel enclosed between closely fitting hemispherical caps of brass, so that the iron sphere was held by and heated in the brass, and thus allowed to heat and cool slowly, the susceptibility being tested by means of a mirror magnetometer. It was found that during cooling from a white heat the reappearance of magnetic susceptibility was much more leisurely in steel than in soft iron, the *rate* of return to the magnetic state corresponding with the rate of recalescence; where recalescence was absent the susceptibility suddenly returned; where the reglow was pronounced the return to the magnetic state was slow. This is to be expected, for the rise of temperature during recalescence is more than sufficient to carry the iron out of the magnetic condition it had just entered upon by cooling, hence there will be a sudden oscillation at this critical temperature. Ledeboer[5] was, we believe, the first to assign the exact temperature of the loss of susceptibility. He found the susceptibility of iron to disappear at a temperature ranging from 750° to 770°C. Hopkinson[6] more recently has investigated the effect of different magnetising forces on the loss of permeability of iron and steel with increasing temperature, more especially near the critical temperature. Hopkinson found that with very low magnetising forces, less than 1 C.-G.-S. unit, the permeability of *iron* gradually rose up to a temperature of 785°C., when it almost suddenly dropped down to unity; in like manner mild steel at first rose and then suddenly fell at a temperature of 735°C.; hard steel behaved similarly, falling off at a temperature of 680°C. Prof. J. A. Ewing has shown recently,[7] in his beautiful experimental model representing molecular magnets, how a state of magnetic instability may occur in the magnetic metals as a certain critical temperature is approached, the chief facts of permeability and retentiveness, and what Ewing terms hysteresis, being explicable by supposing that a magnetised bar is made up, as in Weber's hypothesis, of molecular magnets but "constrained by no other forces than those due to their own mutual attractions and repulsions." Increase of permeability due to rise of temperature, for magnetising forces far short of saturation, being caused by the expansion and separation of molecular centres creating a reduction of stability. And as regards the sudden loss of susceptibility at the critical temperature, Ewing conjectures that the violence of the oscillation of the molecular magnets at this temperature may cause a state of rotation to be developed, wherein, of course, all magnetic polarity would disappear. Prof. Ewing's suggestive Paper shows us that we may well expect other remarkable phenomena—and abrupt changes in the physical properties of the magnetic metals *are* found to take place—at this critical temperature. The Committee have been engaged in investigating some of these.

I. We will first take the sudden anomalous expansion observed when steel and some specimens of iron wire cool from a white heat first noticed by Gore in 1870, and the corresponding anomalous contraction on heating first noticed by one of us in 1873.[8] The wire steadily expands as the temperature rises till a low red heat is reached, when a halt occurs, then a sudden momentary retraction of the wire takes place, after which expansion continues to the fusing point. On cooling, the wire regularly contracts till a temperature a little *lower* than that at the jerk on heating is reached, when a sudden momentary elongation of the wire occurs, and then contraction ensues till it is cold. If the wire be vertical or horizontal, with or without tension, the effect is equally present. To

perceive the jerk on cooling, it is, however, absolutely essential that the temperature of the wire should be raised above that at which the jerk on heating occurs, otherwise no anomalous effect is observed. In the experiments made by one of us in 1875 but not hitherto published, Barrett found that in some specimens of steel wire *two* anomalous contractions on heating and expansions on cooling were noticed, the feebler one taking place at a lower temperature. Further, that in some specimens of iron *no* anomalous expansion or contraction was noticeable, whilst more generally in other specimens the effect *on cooling only* was noticed, and that usually this effect could be wiped out by a few successive heatings and coolings. But in *steel* the jerk in cooling was always present and was not wiped out, though at first slightly reduced, by repeated incandescence and cooling. Further, judging by the amount of the expansion of the wire, the effect on heating took place, as stated above, at a slightly higher temperature than the jerk on cooling.

A series of unpublished experiments were long since made by the Secretary on the effect (*a*) of the diameter of the wire, and (*b*) of the tension on the wire, the effects observed being represented by a curve. Up to Nos. 14 or 15 B.W.G. steel wire, *i e.*, up to a diameter of about $\frac{8}{100}$ of an inch, there is, at the critical temperature, decided retraction on heating, but at this diameter a halt, with just a perceptible retraction, occurs, and as the diameter increases the halt becomes more and more prolonged, until when No. 3 wire is reached (a rod of $\frac{1}{4}$-inch diameter) at the critical temperature a halt of six seconds takes places in the expansion of the wire during heating, and a halt of twelve seconds in the contraction of the wire during cooling. As regards the effect of *tension* on the wire it has the effect of diminishing the anomalous retraction on heating and increasing the anomalous expansion on cooling. The anomalous contraction on heating appears to wear out in thin wires even of steel, but not the anomalous expansion on cooling. In thicker wires of hard steel, continued heating and cooling appeared to make but little difference. We shall discuss later the cause of this curious wiping out of the jerk by annealing or repeated heating and cooling, and are continuing the investigation with samples of steel of known composition.

II. The permanent stretching of the wire under load occurs only when the critical temperature is reached. At this temperature an abrupt and remarkable softening or plasticity of the iron or steel occurs which renders it extraordinarily ductile. Mr. H. Tomlinson[9] has, already published some interesting experiments on the enormous loss of rigidity which occurs in iron at the critical temperature.

In a series of interesting papers communicated to the Physical Society, he has added much to our knowledge of the physical changes which occur in iron at the critical temperature. Mr. Tomlinson places near 1,000° C. the remarkable alterations he has observed in an iron wire under stress or strain. At this temperature "when stretched by a slight weight it suddenly unstretches, when under a slight bending stress it suddenly unbends, when under a slight twisting stress it suddenly untwists, whilst on the contrary, if it has been previously bent or twisted permanently and then released from stress, it suddenly bends more or twists more as the case may be."[10] Opposite changes occur in cooling. One of us[11] has suggested that the probable explanation of the effects observed by Mr. Tomlinson is due to the difference in the rate of heating and cooling between the interior and exterior of the wire. It is probable that the anomalous contraction and expansion in iron which we have been studying is an effect due to the longitudinal strains in the wire produced by wire-drawing, and which are destroyed by frequent heating; the non-existence or rapid subsidence of the effect in some specimens of very soft iron follows from this explanation, together with the more pronounced and enduring effects noticed in steel. Nevertheless, some other cause appears to exist in hard steel where the effect appears to be more or less permanent. We hope to throw more light on this point next year, as our experiments are being continued.

III. We now come to the reglow or *Recalescence* of iron and steel at the critical temperature first noticed by Barrett (*Phil. Mag.*, 1873), and which M. Osmond has made the starting-point of his admirable investigations. It was noticed by one of us[12] soon after the discovery of recalescence that a faint second glow could be seen; the first and far stronger afterglow being exactly coincident with the sudden elongation of the steel wire during cooling. We now come to M. Osmond's valuable investigations, which commenced in 1886.[13] By means of a pyrometer similar to that used by M. Ledeboer, devised by M. H. Le Chatelier, and consisting of a thermo-electric couple of platinum and platinum rhodium alloy, associated with a dead beat galvanometer, Osmond has made a careful study of the recalescence in iron and steel.

Osmond finds three critical points to exist in mild steel when, during cooling, the temperature remains stationary for a sensible interval of time. These three points he designates $a_1$, $a_2$, and $a_3$; $a_1$ being that at the lowest temperature about 660° C., $a_2$ about 730° C., and $a_3$ about 850° C. In hard steel $a_1$ only is present, but is much more pronounced, and occurs somewhat higher, about 700° C. In electrolytic iron, which, however, contained 0·08 per cent. of carbon, $a_2$ and $a_3$ only are present, occurring at about 720° C. and 860° C. respectively. The temperature of these critical points he finds, just as we found with the anomalous expansion and contraction, to be higher during the heating than during the cooling of the same specimen. Osmond, however, has not noticed any sudden rise of temperature at recalescence, only a longer or shorter halt in the cooling. But this difference probably arises from his mode of experimenting; one of us has pointed out the necessity of precaution in this respect.[14] We have recently repeated our experiments, using a thermo-couple similar to that employed by Osmond, and find that there is not the least difficulty in observing and measuring the sudden large *increase* of temperature that occurs during recalescence. It is only necessary to use somewhat fine wires for the thermo-couple, to bind them to the steel wire under experiment, and wrap the part round with asbestos to prevent too rapid cooling in the air.

The temperature of the critical point Osmond finds, as occurred with the jerk on heating or cooling, to be higher on the up side of the curve (that is, during heating) than on the down side of the curve. Like ourselves, he finds the critical point higher in iron than in steel, and that on reheating the same sample the point of recalescence is lowered somewhat. Experiments we have recently made show that after the first two or three heatings stable conditions appear to be reached, recalescence then occurs at the same temperature and to the same amount on subsequent heatings and coolings. This is assuming the metal to be raised to the same temperature before cooling each time; if the temperature before cooling be not so great Osmond finds that the critical point is raised. Our experiments point rather the other way, but they need repeating. When the cooling of iron or steel is slow recalescence begins at a somewhat higher temperature, and lasts longer than when the cooling is very rapid. Osmond finds that when the cooling is very rapid, by quenching the white hot metal in water, recalescence is entirely absent. The steel is thus hardened, and Osmond concludes that the latent heat of the change which takes place in the metal at recalescence is still in the steel, and he terms it the latent heat of hardening.

IV. The difference in the temperature at which recalescence occurs on the up and down side of the curve of heating, has led two of our Committee independently to suggest the explanation of the remarkable thermo-electric current which is produced in iron and steel by a *moving source* of heat.[15] If an iron or steel wire be heated to redness at any one point of its length, and the source of heat, such as a Bunsen flame, be moved along, an electric current is set up in the direction in which the flame travels. By means of clockwork the flame can be caused to move continuously, and hence a continuous circuit is thereby obtained. There are, however, no signs of E.M.F. in the circuit until the recalescent point is passed; then reglow takes place behind the moving flame and the cooling effect in front. This thermal difference is, we believe, the cause of the resultant E.M.F., for it ceases when the flame ceases to move, and is absent in those metals where recalescence does not occur.

V. The thermo-electric position of iron undergoes a sudden change at the critical temperature. This was first noticed by one of us in 1875. Hot iron is thermo-electrically negative to cold iron, but at the critical point a large increase in the E.M.F. is suddenly developed. Mr. H. Tomlinson[16] has shown that iron at a bright red heat in contact with iron at the temperature of the air develops an E.M.F. of about one-twentieth of a volt, or upwards of twice that between a bismuth and antimony couple with a temperature difference of 100° C. between their junctions. Cumming was the first to notice long ago that the thermo-electric properties of iron changed at a red heat, but to Prof. Tait's classical Papers on thermo-electricity we owe the first exact investigation of the changes that heat produces in the thermo-electric properties of iron. "Iron," Prof. Tait remarks, "becomes as it were a different metal on being raised above a red heat; this may have some connection with the ferricum and ferrosum of the chemists, with the change

magnetic properties and of electric resistance at high temperatures."[17]

VI. *The electric resistance* of iron at this temperature also changes; Smith, Knott, Macfarlane,[18] and more recently Hopkinson[19] and Le Chatelier,[20] have published investigations on this point. Hopkinson finds a change in the temperature coefficient of the iron wire he used at 855°C., and of hard steel wire at a somewhat lower temperature. These temperatures he found practically coincident with the sudden loss of magnetic susceptibility of the metals. Le Chatelier finds mild and hard steel show two changes of curvature in their electric resistance, one at 850° C. and the other at 710° C., whereas manganese steel, in which we find recalescence to be absent,[21] shows no such change, the curve of increased resistance with temperature being perfectly regular. Le Chatelier also finds that pure nickel undergoes a sudden change in its electric resistance, the temperature coefficient altering at 340° C., which corresponds to the temperature of other changes in its physical properties.

VII. Some recent experiments made by Dr. E. Ball[22] appear to indicate that there is a still higher critical point than those observed by Osmond and ourselves. Dr. E. Ball has measured the tensile strength and roughly the magnetic state of iron and steel suddenly cooled down from different high temperatures. He finds that there are three critical points when a change in the tensile strength and magnetic character of iron and steel occur with sudden quenching: two of these points agree with Osmond's $a_1$ and $a_3$, but the third point is higher than either of these; he estimates it approximately as 1,300°C. More exact means of measuring the temperature and magnetic susceptibility are, however, necessary.

VIII. This higher temperature is near that at which M. Pionchon[23] has found a change in the *specific heat* of iron. Pionchon's results show that the specific heat of iron changes suddenly between 660° and 720°C., and again between 1,000° and 1,050°C., considerable absorption of heat taking place at these temperatures. The lower of these temperatures corresponds with the recalescent point and loss of magnetic susceptibility in steel. Mr. H. Tomlinson, as already noticed, has also observed two critical points in iron, one about 550°C., and the other at 1,000°C.,[24] when a sudden change occurs in the viscosity of this metal. No doubt these are the same points as those observed by Pionchon, for the variable composition of the iron also, and errors in determination of these high temperatures are probably sufficient to account for the differences observed.

The *amount of heat* given out during recalescence we have estimated from the observed expansion of the metal that occurs during recalescence. Taking Pionchon's determination of the specific heat of iron at a red heat, the heat liberated in the recalescence of a specimen of iron would thus appear to be somewhat over 100 times as much heat as would raise the same mass of iron 1°C. Dr. Hopkinson,[25] from the length of the break in the time curve of cooling, has estimated that the heat liberated in the recalescence of hard steel is equal to 173 times that liberated when the same material falls 1°C. The amount of recalescence in hard steel, as already stated, is considerably greater than that in iron.

IX. Here it may be mentioned that the hardening of steel by sudden quenching in water cannot be produced unless the metal be raised to the temperature of recalescence.[26]

X. We must now consider the general cause of these phenomena The secretary of this Committee long since suggested it was probably to be found in the carbon present in the iron, as recalescence was most marked in those specimens of iron and steel which contained larger percentages of carbon, and this cause Osmond has now, we think, satisfactorily established.

Recalescence in *steel* Osmond attributes to the chemical combination of the iron with the carbon present in a free state, and which has been liberated by heat. Thus the point of recalescence is that at which iron carbide, $Fe_3C$, forms; a body which is stable at ordinary temperatures but decomposed, with absorption of heat (producing the chilling effect observed on heating) at a red heat. Now the heat of combination we find to be about 3,000 calories per gram of carbon present in the iron, as deduced from Hopkinson's estimate of the amount of heat liberated during recalescence; further experiments on this part of the subject are necessary, and we hope to make them shortly.

Recalescence in *iron* Osmond attributes to an allotropic change which he believes iron to undergo at a temperature of about 750° C. Below this temperature iron exists in one molecular state, which Osmond designates $\alpha$ iron, between 750° and 850° the change is in process, and above 850° C. he asserts that iron enters the other molecular state, which he designates $\beta$ iron. It is, then, to the latent heat of allotropy that Osmond attributes the recalescence observed in iron, heat being absorbed to produce this change at the critical point during heating, and liberated during cooling at a somewhat lower temperature. Iron, according to this hypothesis, is a polymorphous element like sulphur, phosphorus, &c. Sudden cooling from a white heat, when the change into $\beta$ iron has occurred, should tend to preserve the iron in this allotropic state; but this is not the case, except to a small extent, and hence Osmond maintains that it is the presence of carbon in the iron which keeps the iron in the $\beta$ condition when suddenly cooled. Hardened steel would thus owe its properties principally to the presence of $\beta$ iron, which is hard and brittle at ordinary temperature: "both the iron and the carbon in hardened steel preserving more or less completely in the cold the condition which they possessed at a high temperature."

We think, however, that the evidence adduced by Osmond on behalf of his theory of recalescence in iron is as yet insufficient. No doubt iron does exist in an allotropic modification at a high temperature, but the electrolytic iron with which Osmond experimented contained 0·08 per cent. of carbon, very nearly as much as some of the pure steels with which we have experimented, which contained 0·1 per cent. of carbon. It is to the influence of this small amount of carbon present in Osmond's electrolytic iron that we are inclined to attribute the feeble recalescence which he observed in his specimen. The effect (*a*) of this residual carbon, and (*b*) of the mechanical treatment the specimen has received, such as hammering and wire-drawing, have yet to be investigated, and this we hope to undertake during the next year. If it be possible to keep iron in the $\beta$ condition when cold, it should not only be hard and brittle but *non-magnetic*, and this has not yet been proved. We have made some experiments on this point by suddenly quenching at a white heat fine iron wires in cold mercury, and here will merely state that their magnetic susceptibility was not destroyed. Manganese steel, it is true, is practically non-magnetic, and this Osmond attributes to the part played by manganese in fixing the iron in the $\beta$ condition, and Hopkinson has shown that whatever slight magnetic susceptibility is found in manganese steel could be accounted for by a few little bits of pure iron distributed through the mass.[27]

We believe that the difference in the temperature position of recalescence (and also of the jerk) on the up and on the down side of the curve of heating or cooling is analogous to what is found in the heating of water. In a clean vessel water may be raised above the boiling point, suddenly at some one point steam is formed, and the whole rapidly passes into steam, the change of state being accompanied by a *fall* of temperature and large absorption of heat. Similarly steam in cooling down may be lowered below the normal point of condensation, when from some cause, such as the presence of solid particles, condensation begins and rapidly proceeds, accompanied by a *rise* of temperature.[28] The retardation of this change Mr. Tomlinson[29] considers to be due to the great internal friction which exists in iron at a red heat; in consequence of this the change takes place at a lower temperature than it otherwise would, until at last a sort of explosive action occurs, and the change rapidly runs throughout the whole mass, analogous to what takes place in supersaturated solutions.

This is what we may expect to occur in the magnetic metals which exhibit the phenomena of hysteresis when under stress.[30] The recent paper of Prof. Ewing's on the Molecular Theory of Induced Magnetism,[31] to which we have already referred, throws remarkable light on the various phenomena we have been studying. By means of his beautiful experimental model, Prof. Ewing has shown that the intermolecular magnetic forces alone are sufficient to account for the known facts of magnetisation, and that magnetic hysteresis is not due to anything in the nature of frictional resistance to the rotation of the molecular magnets, but simply to the molecular instability which results from these intermolecular magnetic actions. And, further, that the same cause explains why there is "in magnetic metals hysteresis in physical quality generally with respect to stress, apart from the existence of magnetisation." We shall probably have occasion in our next report to deal more fully with Ewing's explanation, and here can only congratulate the author on the value and beauty of his suggestive experiments.

Connected with this part of the inquiry, we may refer to the interesting results Hopkinson has obtained with an alloy of iron

and nickel. This alloy Hopkinson finds to have two stable conditions, one being magnetic and the other non-magnetic; a high temperature destroys the magnetic state, which can only be resumed by lowering the temperature considerably below the freezing point. The remarkable fact, now explicable by Ewing's experiments, being that this iron-nickel alloy may be either magnetic or non-magnetic at the ordinary temperature, its previous history determining the state in which it remains.

Here we must leave the subject at present; we are well aware that many matters of interest have necessarily been omitted, and that we have inadequately dealt with those that have come under consideration. So many issues of importance, both to the chemist and metallurgist, as well as the physicist, have been opened up by this inquiry that we trust the Committee, which will be enlarged, may next year present a fuller report.

## AN OLD TELEPHONE SWITCHBOARD.

The accompanying illustration and diagrams of connections relate to an old telephone switchboard erected in the first week in February, 1878, at Meriden (Conn.). The illustration and description are taken from an article by Mr. Morris F. Tyler, which appeared in the *Electrical Review* of New York of January 24th :—

Across the top (see Fig. 1) is a row of 16 binding posts; below appear four circles of metal buttons; in the centre of each circle brought off the annunciator point by turning to the right, and the subscriber's line carried to the office telephone and ground by coming into contact with the bar (Fig. 3). After it was learned whom the subscriber wanted, this connection was thrown off and the switch corresponding to the line of the party wanted was turned down to the bar and call was made. After that subscriber was raised, the switch in circle No. 1 was put on No. 1 pin and the

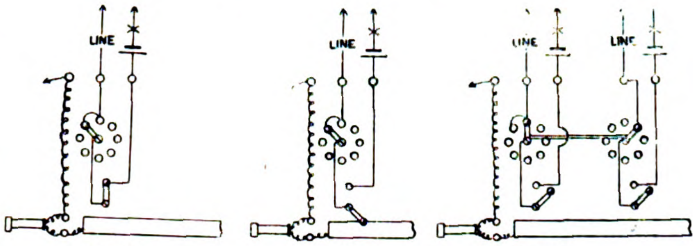

FIG. 2. FIG. 3. FIG. 4.

Diagrams of Connections.

switch in circle No. 2, if it was subscriber on line 2 that called, was put on the second pin, and the ground switch in both instances turned open (Fig. 4). The switches of these circles were connected in pairs; that is, the first and second and the third and fourth circles were connected together. This left the two subscribers' lines connected with one another, but cut out of office telephone, of ground, battery and annunciator, so that the subscriber could

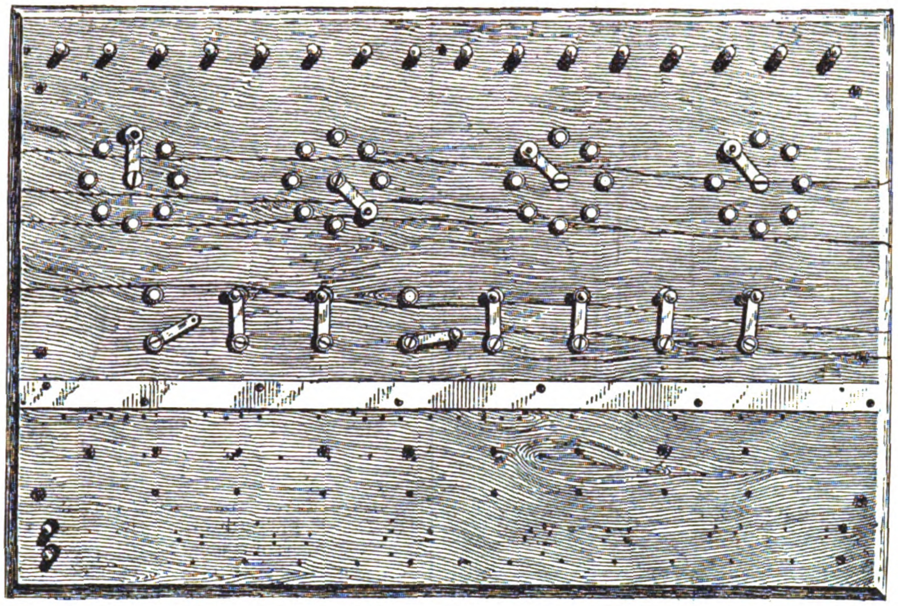

FIG 1.—An old Telephone Switchboard erected at Meriden (Conn), February, 1878.

is pivoted an arm, which can be brought into contact with any one of the buttons. There are eight buttons in each circle. Next below these is a row of two-point switches, playing between a button similar to that in the circles and a continuous strip of metal which is seen across the board below.

In the lower left hand corner are two binding posts, and when the board was in use there was a similar pair in the lower right hand corner. To these two lower pairs of binding posts telephones were attached, the telephone wire running from the upper part of the pair on each side to the end posts on each side of the upper row and thence to ground, and from the lower post to the metal strip. The 14 posts across the top between the two terminal posts are alternately line and annunciator posts. Subscriber's line No. 1 came in, for instance, in the second post of this upper row, then it passed to the top button of the circle immediately under it, and from there was legged across to the top button of each of the circles. From this button in the first circle it passed to the switch below the circle. The button above this switch is connected with the annunciator and battery through the third post in the row. The other point of this switch, or the bar, goes to the telephone and ground in that direction. The next pair of wires was appropriated to button No. 2, or the next right hand button of each circle and went through a similar course of wiring. The button No. 8, or the one to the left of the top button of each circle, is zero point.

When no wire was in use each of these switches rested upon that button, as is shown in the diagram (Fig. 2). That left the subscriber's wire connected with the annunciator by means of the lower switch. When the call was made, the lower switch was not call the central again until the operator, by turning one of the lower switches, threw him on to the office telephone. The switch, as it stands in the illustration (Fig. 1), is set for conversation between parties on lines 1 and 4, with the other lines in calling condition. This switch accommodated seven wires, on which were 50 subscribers, but only two conversations could be carried on at the same time. The whole system was operated on closed circuit.

The primitive character of construction will be recognised from the fact that the buttons in the circles are the heads of carriage bolts, which have been slightly turned down, and were once nickel-plated, and the knobs upon the switches in the circles are knobs used upon tin teapots. The wiring on the back of the switch was of ordinary office or paraffined cotton wire.

## ON THE ALTERNATING ELECTRIC ARC BETWEEN A BALL AND A POINT.*

BY EDWARD L NICHOLS.

The attention of Prof. Nichols was first directed to the phenomenon forming the subject of this paper, by Mr. E. G. Acheson, whose observations may be thus described:—When the secondary terminals of a transformer are metallically connected with a ball and point, placed near enough to admit of a discharge between the

* Abstracted from the American *Journal of Science*, Vol. XLI., January, 1891.

Digitized by Google

two, it is found that a galvanometer shunted around the ball and point indicates a considerable flow of continuous current.

The phenomenon has been recently investigated by Messrs. Archbold and Teeple in the Physical Laboratory of Cornell University. The apparatus employed consisted of a Ruhmkorff coil of moderate size, the interruptor and condenser of which had been thrown out of circuit. The primary coil consisted of a few turns of heavy wire, surrounding a core of iron wires, and was fed from a small alternator with currents reversing 14,000 times per minute. When the terminals of the secondary were brought into position, a brilliant discharge took place which, although appearing continuous to the eye, disclosed its intermittent character by emitting a note corresponding in frequency with the period of alternation.

The terminals of the secondary coil were subsequently connected with a brass ball, about one centimetre in diameter, and with a point consisting of a steel sewing needle. These were mounted horizontally in well insulated bearings, the centre of the ball in line with the axis of the needle. The distance between the ball and the point of the needle was capable of adjustment by means of a micrometer screw. A mirror galvanometer of 2,000 ohms, having in its outer circuit about 100,000 ohms, was shunted around the ball and point (in parallel circuit with the air space between them). When the induction coil was put into operation, the ball and point being too far apart to admit of a visible discharge, the galvanometer needle remained at zero, but when they were brought within striking distance, a large and constant deflection was produced. When the ball and point were interchanged, the deflection was reversed, its direction always being that which would have resulted from a current flowing from the ball to the point. Under the influence of the discharge, which was intensely luminous, the steel needle was fused at the point and rapidly wasted by oxidation, so that it became necessary to find some more refractory material. It was finally supplanted by a pointed platinum wire, which although rendered highly incandescent withstood the temperature of the arc much better than steel had done.

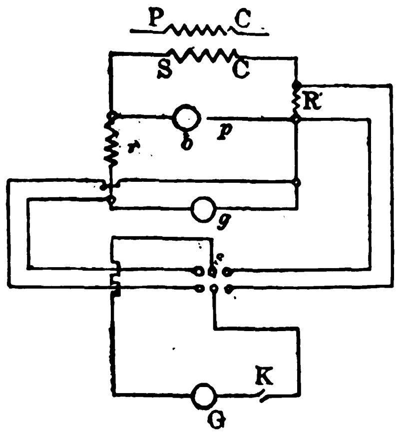

FIG. 1.

As the sparking distance is increased the arc at first forms and sings with an even tone, the point becomes of a dull red colour, while the galvanometer gives a small but quite steady deflection. As the arc is drawn out further it sings louder and more harshly, the point becomes redder, while the galvanometer deflection increases and becomes very unsteady. At a certain critical length the tone becomes smooth and even, the point brightens almost to a white heat, while the galvanometer deflection becomes much greater and very steady. The explanation suggested, and which subsequent experiments seem to confirm, is as follows: At first the arc forms both ways, the rapid succession giving the tone. As the arc lengthens the arc still forms from ball to point, but is only intermittent (occasional) from point to ball, giving the unsteady tone and deflection. Finally the distance becomes too great for the arc to form from the point to the ball, while it still passes freely the other way, and the tone and deflection become steady.

Attention was chiefly directed to the conditions existing when the critical length of arc above mentioned had been reached. In order to do this the length of the arc had to be maintained between very narrow limits, and as small changes in the speed of the alternator destroyed the adjustment, the necessary steadiness was only obtained when the dynamo was driven by a motor supplied from storage cells. The measurements made were such as to determine the periodic changes in voltage and current during a complete cycle—first when no arc existed, and afterwards when modifications were introduced by the discharge. In all the experiments the striking distance was greater than the critical value already defined.

The voltage was measured by a mirror galvanometer of ten thousand ohms resistance. The circuit was completed through an instantaneous contact device, consisting of a wooden disc mounted upon the shaft of the machine. A single bar of brass, on the periphery of the disc, passed under a brush once every revolution. This bar was connected with a brass collar turning under a second brush. By thus closing the circuit for an instant once in a revolution, the voltage of the secondary circuit at that particular time could be measured, and by adjusting the brush the entire cycle could be explored.

The arrangement of apparatus is shown diagrammatically in Fig. 1. P C and S C are the primary and secondary coils of the induction coil, *p* and *b* are respectively the point and ball. R is a non-inductive resistance, *g* the indicating galvanometer, in parallel with the ball and point, *r* a non-inductive resistance, *s* a switch by means of which the Thomson galvanometer could be shunted at will around R or *g*. K is the instantaneous contact device, and G is the Thomson galvanometer. When the Thomson galvanometer was shunted around R, which was placed in the main circuit leading from the induction coil, it served to indicate the current flowing in that circuit during that portion of the cycle for which contact was being made; when connected in shunt with the galvanometer *g*, it measured the fall of potential through the coils of the latter instrument. The function of the indicating galvanometer during this part of the investigation consisted in showing, by the size and direction of its deflection, whether the discharge between the ball and point continued to maintain its proper character.

The result of the experiments is shown in Fig. 2. Curve A shows the variation of current when the arc is extinguished. It is of the usual sinuous character. Curve B shows the cyclic charges of current when the arc was playing.

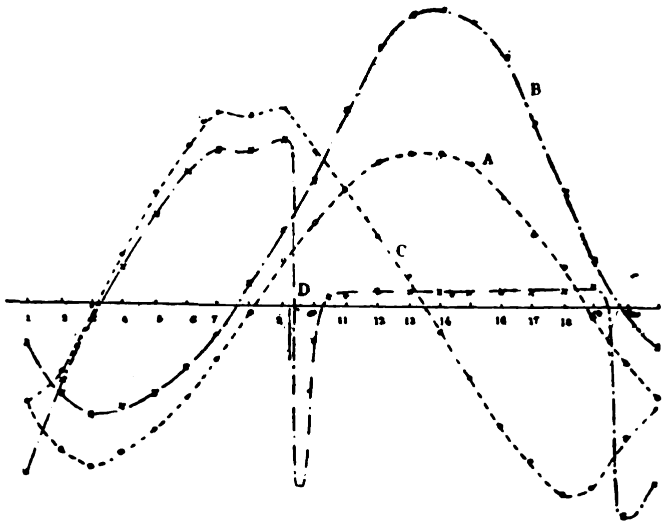

FIG 2.

Abscissæ represent portions of a complete cycle, the period being divided into 20 equal parts, ordinates the relative amounts of currents through the resistance R, or the total current in the secondary circuit. Deflections, when the current flows from ball to point, are plotted above the base line, as may be seen from the curve B. The current flowing in the positive direction during each cycle was greatly in excess of that flowing in the negative direction, when the discharge was taking place between ball and point; whereas when no arc was formed (curve A) the areas enclosed by the positive and negative branches of the curve were equal. Now there were two paths offered to the current, that through the galvanometer *g*, and the resistance *r*, which consisted of a column of copper-sulphate solution between copper poles (approximately 112,000 ohms), on the one hand, and the parallel circuit between the ball and point on the other. The resistance of the latter path was infinite whenever the arc was interrupted, falling to finite values during each discharge. Increase of current through R indicates, therefore, the formation of the arc. Such increase is found to exist during the second half of each cycle, that is to say, during that interval in which the ball is positive; and it might be inferred from these curves alone that the discharge was an intermittent one taking place always from ball to point. Other curves, taken simultaneously with A and B, the Thomson galvanometer being shunted around the indicator galvanometer, lead to the same conclusion. The curves marked C and D (Fig. 2), show the results obtained. Owing to the high self-induction of the galvanomer, and to the frequency of the current, the fluctuations in voltage do not correspond in time with the fluctuations in the current flowing through the resistance R. The lag in fact amounts to nearly 90° of phase. The curves are, however, of some interest and show that when the arc is extinguished (curve C) the positive

Digitized by Google

and negative fluctuations are of equal amount, while when the arc is playing (curve D) the positive predominates. To obtain the voltage curves between ball and point directly, a noninductive resistance was substituted for the indicating galvanometer, and the measurements from which curves C and D had been drawn were repeated. Of the two curves thus obtained, that taken when the arc was not playing (E. Fig. 3) is a sine curve closely coinciding in phase with the simultaneous current curve (A. Fig. 2); and the corresponding curve F, taken while the discharge was passing, is in its essential features of the same character as curve D.

The results exhibited graphically in these six curves afford abundant verification of the theory of the ball and point phenomenon, given in a previous paragraph; and they establish the fact that in the secondary circuit of a transformer, such as that made use of in these experiments, the striking distance from ball to point exceeds that from point to ball. It follows that whenever the space between the ball and point is less than the former and greater than the latter distance, discharge will occur only during that portion of each alternation for which the ball is positive, and that under such circumstances a galvanometer placed in the circuit will show a constant deflection.

Complete corroboration of the foregoing conclusion was obtained by studying the image of the arc in a revolving mirror. With a discharge of less than the critical length, the discharge was seen to

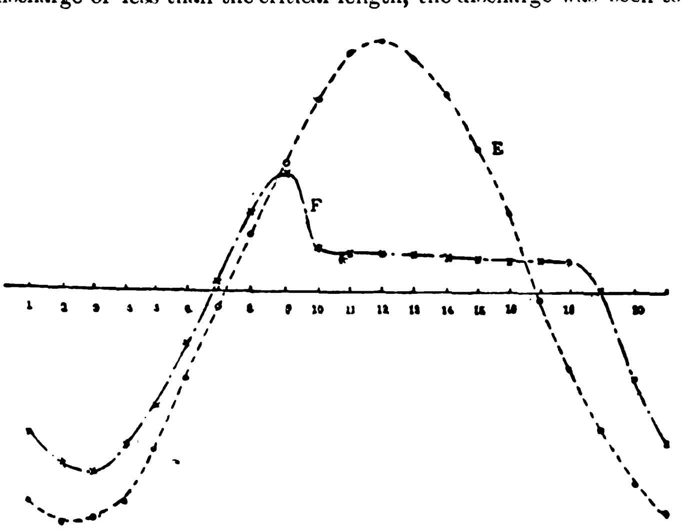

Fig. 3.

consist of two distinct sets of sparks, all of the same duration, but differing in colour. Each alternate discharge was purple, the intermediate ones being of a greenish cast. The spark-images were everywhere equidistant, and their duration was about four times as great as the intervening intervals of darkness. The extension of the sparking distance beyond the critical point resulted in the complete suppresssion of the series of purple images, the intermediate ones remaining undisturbed in position, duration, and appearance.

## THE APPLICATIONS OF GEOMETRY TO PRACTICAL LIFE.*

BY PROF. KARL PEARSON.

There is scarcely any branch of modern science which has of recent years made such progress as geometry; there is certainly no branch over the purport of which there is so much obscurity or has been so much discussion. On the one hand, geometry, like most sciences, was born of a practical need. The Egyptians, an eminently practical people, were not interested like the Greeks in the properties of the circle for the circle's own sake, but they wanted an art to measure the capacity of their barns and the size of their haystacks, and to plan out their pyramids and great buildings. But, above all, they were landowners, and to sell property they required to measure land—to measure it in square feet, and not by the time that a yoke of oxen would take to plough it, which was not always an exact or convenient test. So the Egyptians invented land-measuring or surveying, and termed it *geometry*, and the geometricians they called *rope-stretchers*.

On the other hand, the Egyptians, having satisfied their immediate wants, left geometry uncultivated, and by not pursuing it on purely theoretical grounds failed to convert it into that great instrument of investigation which in the end was to master the mystery of the heavens, guide the mariner, or help the engineer.

The next stage in the development of geometry was left to the Greeks, for whom to apply geometry to practical purposes would have been to debase it. They studied geometry for its own sake, much as some of our friends to-day study metaphysics, only, it seems to me, they did it to more purpose. They recognised in geometry a great instrument for sharpening the intellect, and they made it the basis for a sound education. A proposition was to them a delight in itself, and to deduce a new one a distinct intellectual advance. Thus they had the proverb, "A figure and a stride: not a figure and sixpence gained."

I have said enough, perhaps, to indicate how the two tendencies of modern geometry, and, indeed, of the whole of modern science, date back to the very beginnings of scientific activity—to the practical Egyptians, whose horizon was bounded by the immediate needs of life, and to the dreamy, metaphysics-loving Greeks, who despised practical applications. There are few teachers of geometry who will not have felt at times the burden of these two tendencies. The great mass of material in the form of published papers on higher geometry, many of which can only be understood by the initiated few, and some of which have probably never been read except by their writers—this weighs at times upon the mind and makes one, without despairing of science, cry, "*Cui bono?* For whose good? How can this help the progress of mankind?" On the other hand, how the listless student, bent on struggling through life with the least expenditure of intellectual energy—how he calls up the spirit of the Greek, when he languidly asks his teacher after lecture, "What is the *use* of this? I've got the result in 'The Engineer's Pocket-book.'" For *him* the insight to be gained by seeing the *how* and *why* of a process is of no importance, and the fingers tingle to hand him threepence that he may at least gain something by attending our lectures.

It is not my purpose now to trace these practical and theoretical tendencies through the history of geometry down to the present day. Neither do I intend to emphasise one tendency at the expense of the other. But of this fact I feel clearly and absolutely certain, that a divorce between the two—such as has existed in some of our great mathematical schools—is wholly unnatural, and tends sadly to retard the efficiency of both. What we are slowly but surely learning in this country, owing to the pressure of foreign competition, is that education and theory are needed in all branches of practical life if we are to maintain our industrial position. But it must be education and theory which is sympathetic to practice, can indeed be wedded to it, and takes upon itself no cynical and superior airs. When we compare on the one side the vast amount of mathematical talent out of touch with all human needs, and on the other the amount of practice which limps along for want of theoretical support, we cannot but be grateful for any institution or foundation which tends to promote a better fellowship between the two. This union of theory and practice, with its offspring the applied sciences, has nowhere in recent times met with more cordial support than in the City of London. Within the last 20 years the science of engineering has been revolutionised; from an empirical and mechanical craft, engineering has been raised to the rank of a learned profession. The introduction of theory into engineering practice has been largely due to the progress of modern geometry and the geometrical methods of calculation.

Problems, which when clothed in mathematical symbols only served to appal the practical man, became intelligible to him when hieroglyphics were replaced by curves upon the drawing-board. The success of this particular union of practice and theory is largely, I believe, due to the choice of a geometrical method, to the recognition that form and figure are more easily realisable by the average mind than symbol and numeric quantity.

I have referred to the union of theory and practice which has been so largely realised of late years in engineering construction because it offers us a striking example, not only of the success of theory as applied to practice, but also of the manner in which that theory, in order to be successful, must be applied. The theory does not need to be superficial, but it must be of a kind which the practical man can grasp; the calculations must be made in a form which appeals to his imagination, and in the particular sciences preliminary to the engineering profession this has been largely done by the aid of geometical and graphical methods. Twenty years ago these methods were scarcely discovered, or the few known were neglected or scouted. To-day the most scientific Government in Europe permits the calculations and plans of the largest engineering structures which are submitted for its approval to be made by purely graphical processes. Here, then, we have an instance of theory placing at the disposal of practice one of the most efficient instruments of modern calculation and investigation, and this, indeed, is peculiarly the light in which, owing to early tradition and present needs, geometry ought, I think, to be dealt with. The Renascence, with its revival of learning, had resuscitated the knowledge of the Greek geometry. But the minds of men

* Abstract of a probationary lecture delivered at Gresham College, on Friday, December 12, 1890. The historical facts of this lecture are chiefly drawn from two excellent books—Gow's "History of Greek Geometry," and Ward's "Lives of the Professors of Gresham College."

Digitized by Google

were not content with pure theory; they were anxious to understand the laws of the physical universe—astrology was being replaced by astronomy, chemistry was deposing alchemy. The old forms remained, but they were filled with a new life. Sir Thomas Gresham, indeed, when he founded his College established his seven professorships on the lines of an old mediæval University, in which all knowledge was forced into one of the seven divisions—divinity, astronomy, geometry, music, law, physic, and rhetoric. But what a very different view the early science professors—those of astronomy and geometry—took of their subjects to what would have been possible a hundred years earlier! Geometry for them meant the application of mathematical knowledge to all the branches of physical science. It was not for them the pure theory of lines and circles and curves, but a process of calculating and investigating the facts of Nature. Thus the revival of geometry in the sixteenth and seventeenth centuries was on Egyptian rather than Greek lines. Newton, with astounding ingenuity, used geometry as his main instrument for investigating the motions of the moon and planets.

I have no wish to minimise the educational value of purely theoretical science. I recognise how great a factor it has been and is in the intellectual and spiritual growth of the nation. Investigations like those of Darwin and Maxwell, which appear at first sight to have no practical applications, may profoundly alter our whole view of human life, or of the physical world which surrounds it, and in doing this may modify indefinitely our practical conduct or our command of the forces of nature.

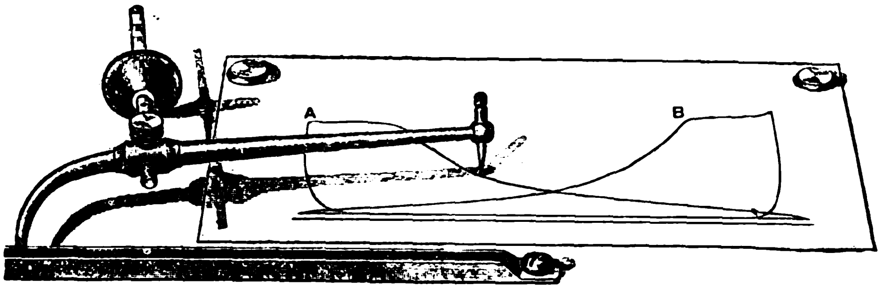
Even geometry in its more abstruse speculations, when it transcends the space in which we live and theorises of another, of which ours is as poorly representative as a landscape painted on flat canvas is poorly representative of the wealth of form and distance in the scene it depicts—even this abstruse geometry may some day react on practical life, by the modifications it is capable of producing in the current ideas of space and force. I recognise to the full this educational value in geometry, and in all forms of pure science; but I believe that there are other institutions—notably the great Universities—which sufficiently emphasize this side of learning.

In particular, it seems to me that the lectures on geometry can be made especially serviceable in this direction, if geometry be interpreted in the wide sense current in the seventeenth century, and which it retains to this day in France. The modern development of graphical and geometrical methods has placed a powerful instrument of calculation and investigation in the hands of those who have neither the time nor opportunity of learning to handle the abstruse tools of analytical mathematics. Wherever quantity of any sort has to be measured and reasoned upon, there these geometrical methods find their applications. Their applications are, indeed, so manifold that it is difficult to enumerate them; to questions of force and motion, to problems in the strength of materials, in the structure of bridges and roof-trusses, of machinery in motion, of cutting and embanking—they have been long applied, and form the basis of much of modern engineering practice. But there are other fields, the graphical representation of statistics at once suggests itself. Mortality, trade, goods and personal traffic, furnish statistics which if dealt with in a graphical manner very often suggest conclusions which are of the greatest interest to those dealing with problems of insurance and commerce—conclusions more readily deducible from the geometrical than from the numerical representation of statistics. The like geometrical methods have in recent years been applied to the principles of political economy, till the theory of prices has become almost a branch of applied geometry.

But it is not alone in these very specialised subjects that we may reason geometrically. The whole field of physical science is occupied with the investigation, representation, and reasoning upon *quantity*, and therefore is essentially a field for the application of geometrical methods, but the bearings of physical science on practical life are too wide and too well known to be enlarged upon now.

## HINE AND ROBERTSON'S PLANIMETER.

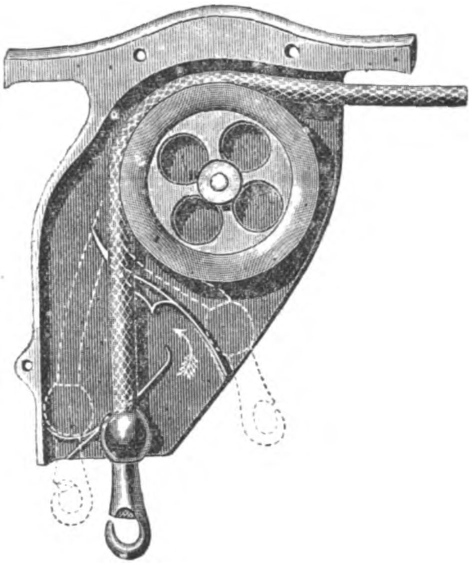
**A novel integrating instrument of great simplicity, designed for the special purpose of furnishing a ready means for measuring indicator diagrams simply and rapidly, is described in the *Electrical World* of New York. From its construction, it will be observed that the slipping motion of the wheel in running over or on to the card, which is a source of error in the Amsler planimeter, is in a very large measure avoided. The record wheel is knife-edged and free to move on its spindle, and reads by the distance it has travelled along its axis, instead of with a vernier as is usual. In operating the instrument it is only necessary to slip the wheel against the shoulder which forms the zero point on the scale, and then trace the diagram with the tracing point from the upper left corner of each card, in the direction in which the hands of a clock move. The scale engraved on the spindle gives, on completing the tracing, the number of square inches in the card. This new instrument is said to work very satisfactorily for the purpose intended. Its merits are simplicity, and the ease and rapidity with which it can be manipulated, without special delicacy in adjustment.**



Hine and Robertson's Planimeter.

## THE CUTTER ARC LAMP SUPPORTING PULLEY.*

In this ingenious device the arc lamp is hung on a hook, whose large knob is engaged by projecting ridges, which automatically support the lamp when raised, or release it again when about to be lowered. This is accomplished without the addition of any moving parts, in the manner shown in the accompanying illustration. On raising the lamp the knob is guided by the raised ridges until it strikes the curved stop; then on slackening the hoisting rope, the knob is pulled down by the weight of the lamp into the recess in the lower corner of the pulley. The lamp is then supported entirely by the pulley, so that the hoisting rope may be loosened, or even cut, without letting the lamp fall. To release the lamp, it is raised until the knob has passed the corner of the upper ridge, when it will



Interior of the Cutter Pulley.

* From the *Electrical Engineer* of New York.

Digitized by Google

be guided out (as shown by the dotted lines in the cut) and the lamp can be lowered.

Both the engaging of the hook and the releasing are accomplished in turn by raising the lamp till the knob strikes a solid stop, and then slackening the rope. This leaves no time to be wasted in trying to stop at some exact point, or to disengage a series of interlocking cams, but makes the action as positive as it is simple. The method of fastening the pulley to the suspension wire is also new, and requires no bolts or screws to keep the pulley in its place. The suspension wire rests in the grooved upper edge of the pulley and is held there by two wires wrapped around the ends of the pulley. The kink put into the suspension wire by this method of fastening effectively keeps the pulley from slipping along the wire, the more so as there is no tendency for this, excepting while the lamp is being raised or lowered.

## AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January* 23, 1891.

**The Lapse of the American Telephone Patents.**—There is a possibility of some interesting moves in telephonic matters before long. The original Bell telephone patent expiring, as it does, in 1893, cannot much longer afford protection to the Bell Telephone monopoly. Besides this the important transmitter patent, patented in this country after its appearance in England, will soon expire, and the Bell Telephone Company consequently is undoubtedly casting about for means to prolong its monopoly. It already controls the Edison carbon telephone patents, and a very large number of other important claims, but these are not enough to secure any considerable prolongation of its life as a monopoly. Rumour has it that there is a possibility of the notorious Daniel Drawbaugh appearing in rather a new *rôle*. As his patent was applied for in July, 1880, it stood no sort of chance against the early Bell patents by reason of their having been for two years in public use. But among the numerous claims made by Drawbaugh was one for the invention of a carbon transmitter; the application in question is antedated by something more than two years by Edison, but, inasmuch as the Edison carbon transmitter had not perhaps been in public use for the legal period of two years, Drawbaugh's contention could be revived if it became necessary to do so. A patent for the carbon transmitter granted to Daniel Drawbaugh, and bearing date from 1891 or 1892 would be most convenient for the Bell Telephone Company, and inasmuch as it controls the only claims with which the redoubtable Daniel would be likely to come in conflict, it has been suggested by some electrical gossips that an effort may be made to deck out Drawbaugh in in the garb of a prior inventor. It is understood that the Drawbaugh Company, notorious through litigation a few years ago, has been approached with reference to the subject. Another interesting rumour is to the effect that the Western Union Telegraph Company is about to make an onslaught upon the Bell Telephone Company, based on the agreement entered into between the two by which the latter was not to enter into active competition with the former. With the present state of the long distance telephone service, and the great additions to it that are likely to be made, the telegraph company is beginning to feel that its privileges are being encroached upon.

**The Rapid Transit Problem in New York.**—Vigorous efforts are being made to push a Bill through the New York Legislature to facilitate rapid transit work in New York. This subject is now being actively discussed, and the chances are that some sort of a Rapid Transit Bill will be passed ere long. There is some danger, however, that it may be passed in such form as to play into the hands of the elevated roads, which, however useful they may have been, and still are, for certain purposes, give very feeble promise of anything like adequate rapid transit. Engineers with arcade schemes, viaduct schemes, and tunnels are becoming as plenty as primary battery inventors, and the time of the Rapid Transit Commission is largely taken up with meditating on their respective proposals. It is too early yet to venture any prediction as to what the outcome will be, but the public is thoroughly aroused, and something will have to be done, and done quickly.

## CORRESPONDENCE.

### ELECTRIC AND MAGNETIC THEORIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with interest Mr. Sprague's letters in *The Electrician* and elsewhere. It seems to me that he has confused several points, and thus included under his sweeping condemnation many things which are quite beside the point at issue. Leaving out the question of electrolysis and discharges through gases, we may divide the subject into three heads.

1. Faraday's experiments and theories on electrostatic and electro-magnetic induction, and Ohm's law; these were expressed by Maxwell in mathematical language, and together with the work of such men as Coulomb, Gauss, and Ampère constitute the whole of his first volume and about half of the second. The relations between the different quantities which Maxwell deduces are the direct expression of experimental facts, and can only be doubted by those who are prepared to doubt Faraday. As yet it must be noticed there is very little, if any, mention of a medium which may not be ordinary matter, and what mention there is does not in any way involve the accuracy of the expressions, since they rest in the firm basis of Faraday's researches.

2. Maxwell's theory of the nature of displacement currents and the electro-magnetic theory of light.

This theory *assumed* that the true electric current consisted not only of currents in conductors, but also of the rate of variation of electric "displacement" in dielectrics, and that this latter part produced the *same* magnetic effect as the part in conductors. (*See* Maxwell's "Electricity and Magnetism," Vol. II., page 234, § 610.) This was an assumption, and could only be proved by the manner in which experiment verified predictions based on this theory. For a long time this proof was wanting, and other theories not involving this assumption were proposed. From his theory Maxwell developed the electromagnetic theory of light, and calculated what the velocity of electro-magnetic waves, if they exist, depends on; and what is more, he proceeded to determine this velocity by experiment, and found that it is very much like that of light.

It is well known that the existence of electro-magnetic waves has been demonstrated by Dr. Hertz, of Bonn. As yet there is no positive assumption of anything beyond ordinary dielectric, and Maxwell's theory need by no means be false if there be no such thing as ether. The existence of waves was predicted as a direct consequence of Faraday's discoveries, with *one* assumption. Calculations have been based on Maxwell's theory, and have been the means of predicting many phenomena which have been verified by experiment, notably Mr. Heaviside's investigations, at which Mr. Sprague seems to stumble very much. In these the word "ether" certainly occurs, but it by no means follows that the results would be false if there be no ether.

3. We next come to the attempts which have been made to give a mechanical explanation of the phenomena of light and electricity. It is to these, I gather, that Mr. Sprague particularly objects.

First, Green proposed to explain light by the existence of an elastic solid ether which seemed to give a very fair account of many of the phenomena observed, and was by no means an unpromising proposal; but yet there were great difficulties in the way of its unreserved acceptation; for instance, that it introduced the necessity of a longitudinal wave in addition to the transverse waves, and the difficulty of accounting for the motions of the planets, if space were filled with such a substance. Then there was Sir William Thomson's attempt to get rid of the necessity of a longitudinal wave by a peculiar relation between the rigidity and compressibility of the ether (*Phil. Mag.*, November, 1888). This has given very satisfactory results on many points; and may be regarded as an advance towards the true explanation. It must not be forgotten that the proof of such theories lie in their ability to explain *all* the phenomena.

Digitized by Google

Then since many electric and magnetic phenomena are not such as we are accustomed to connect with matter as we know it, it became a question as to whether they could be explained by the action of an ether; and since, as Maxwell remarks, it is unphilosophic to fill space with two or three ethers, it seemed necessary that both light and electric actions should be caused by the *same* ether, and this is further confirmed by the velocity of electro-magnetic waves. To explain electric and magnetic phenomena something of the nature of a whirling motion appears to be necessary, hence it became a question whether an explanation could not be given by means of fluid motion; this would escape the difficulty of the motion of the planets to at least a great extent.

The attempt has been made by Sir William Thomson and Fitzgerald, who have shown that if space were filled with a certain arrangement of vortices in a perfect fluid light could be propagated, and that there was some hope of explaining electric and magnetic phenomena as well. There the matter apparently rests at present, and cannot be decided one way or the other till it has received a great deal of close study, and has been verified, or otherwise, by experiment.

The above is some, though doubtless very imperfect, statement of the matter at issue, and may, I hope, tend to render Mr. Sprague's objections a little more definite in their form, as it is difficult to meet objections of a very general and hazy character.

Mr. Sprague and Prof. S. P. Thompson appear to be at variance about Ohm's law only through not understanding the meaning of each other's language, so that there is no necessity to discuss that question further.—Yours, &c.,

R. S. Cole.

Emmanuel College, Cambridge, January 31, 1891.

---

TO THE EDITOR OF THE ELECTRICIAN.

Sir: To avoid any confusion in discussing the subjects indicated by Prof. S. P. Thompson, it will be well to commence with a few definitions and explanations. The fundamental point is whether electricity, or electric energy, is transmitted by ether or by ordinary matter. I define ether as a hypothetical substance (in the metaphysical sense of the word), the existence of which would never have been suspected but for the fact that light traverses space; when action at a distance was seen to be hardly conceivable, it was necessary to conceive that there was *something* in space to transmit action. But we know that there are properties which it cannot possess, those very properties by which we define matter, viz., gravitation force, internal friction, which would cause loss of energy in transmission, and external friction or resistance to the motion of matter. Now, it appears to me that with these properties vanish the whole of the mathematical reasonings about the properties of the ether; because, as it can possess no momentum, and can take no structure, as this depends on friction, it does not come within the range of mechanical laws. All the notions about density, rigidity, elasticity, &c., are simply the result of treating this imaginary (though probably existent) substance as though it possessed properties which we are quite sure it does not possess.

Matter I define as substance, in the usual sense of substantial, affecting our senses, and capable of measurement and of experimental examination and consisting of the elements discovered by chemistry, possessing a structure based upon its own existence in the forms of molecules, atoms, and probably sub-atoms, and being the agent which manifests the existence of energy or forces.

To avoid any cacophony about mere words, I repudiate all ideas about what is called the "essence" of matter, or any interest in the question of what it really is. All this is of no concern to us. It belongs not to science, but to metaphysics. For the same reason I pay no attention to a fashionable notion that the imaginary ether is capable of being condensed into or combined with matter, and is the real cause of the properties of matter, or some of them. That also is no concern of ours. All I say as to it is, that if "ether" forms part of the constituents of matter, and if an atom of matter has, as part of its essence, some ether, then that atom is what I mean when I speak of matter. I use the term purely as the expression of observed facts, apart from any notions as to the cause of those facts, which it is very certain no one knows anything at all about, and it is most probable no one ever will know anything. Longfellow may be right when he says, "things are not what they seem;" but our business is with what seems. Our cognisance is of phenomena and their relations, not of essences and ultimate causes.

Dr. Lodge spoke of what I have done by "my own methods;" as far as they are merely personal they would be of little interest, but if they involve a fundamental principle, they are of great importance, and I will state what my method is. The definition is clear and simple. I look at all natural phenomena with the eye of a chemist, and examine them with the means and by the principles of chemistry. Now chemistry is the most exact of all the sciences, and the most definite in its working; but of all the sciences it is the least influenced by mathematics: it deals with *things*, not with *abstractions*. On the other hand, most electricians, practical and theoretical, study electricity from the mechanical point of view; all the systems of measurement are based upon abstractions, mass, time, and space, which are indefinite because arbitrary. In other words, the mechanical or mathematical mind is directed to the functions of energy, while that of the chemist is directed to the functions of matter and its structure, and compelled to work on lines laid down by nature. Now energy and its relations are the legitimate field of mathematics, and are capable of being dealt with in endless abstractions. And let me say one thing as to the functions and effects of mathematics: they are to the mind what the cart and the harness are to the horse; they enable him to do much valuable work, but they enslave him. It will be seen, then, that what Dr. Lodge calls my methods are no mere peculiarity of my mind; the same mode of working can be seen in all who are chemists, rather than mathematicians; it is very strikingly shown in the methods of Faraday and of Prof. Crookes, and in the result of their thoughts. I am quite sure that Mr. Heaviside has (very naturally as a mathematician) quite misunderstood the nature of mind, when he said, p. 331, "Unfortunately, in my opinion, Faraday was not a mathematician." No, had he been one, he could not have been what he was; his natural energies would have been "cribbed, cabined, and confined." He would have been Pegasus in harness; he would have been like David, mighty to conquer with his own simple weapons, helpless in the armour of Saul, valuable as that might be in itself.

The specific subject which I propose to examine is the mode in which what we call an electric current is propagated, and in what manner energy is related to it, and transmitted in connection with it. I assume that we are all agreed that the current and the energy originate in what we may call "the source," be it a battery, a dynamo, or thermopile, where energy is, by some agency which we are not now concerned with, in some way related to and impressed upon what we may agree to call a "circuit," because definite in space and direction. I assume also that no one will dispute that there are two orders of circuit, the *inductive*, in which stresses can be set up electrically, and the *conductive*, in which the phenomena which we call the electric current are produced. In my next letter I shall start from these to see how Ohm's law deals with them.

Meanwhile, I wish to suggest to Mr. Heaviside, as our chief term coiner, to adopt a word from me. He has given us inductance instead of induction, which was too general, conductance instead of conductability, and so on, with many useful modifications. I think we might take a hint from chemistry and make prefixes and terminals indicate orders of facts, and the terminal "ance" is being so used. I wish we could get rid of "resistance," and especially that dreadful "magnetic resistance," and substitute something else for the reciprocal of conductance and permeability; in fact, ought not this last to be *permeance*, as being a passive property, not an action? What I want, however, and mean to use, is a term corresponding to inductance, the electric reaction, say *magnetance* for the magnetic reactions of electric circuits. They are both, in my views, temporary storages of energy, effected by specific properties of matter.—Yours, &c.,

John T. Sprague.

## RESISTANCE COILS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: On page 649 of your issue dated October 10, 1890, the following words occur:—"The series resistance is not wound with a looped wire, as is usual in resistance boxes, because this method is not good, the insulation being apt to break down. A single wire, therefore, was used. When one layer was wound, the bobbin was reversed in the lathe, and the next layer wound in the opposite direction, a thin layer of insulation being put between the layers. This method secures absence of self-induction, and good insulation, as the beginning and end of the coil are kept well apart."

In your Editorial Notes on page 1 of the present volume, dated November 7, 1890, you draw particular attention to this mode of winding in connection with the work of M. Chaperon, and further remark:—"This method has already been used by Mr. Swinburne in the construction of non-inductive resistances for wattmeters."

Permit me to draw your attention to my Patent, No. 2,263, May 24, 1881. On page 5, beginning at line 35, you will find—"I will now explain the manner in which I construct my resistance bobbins. Hitherto in winding resistance coils the wires have been wound on double in order to obviate inductive effects, but this mode of winding has the disadvantage of not securing good insulation. I now propose to wind the coils with a single wire helically, and reverse the direction of the winding in every layer, placing between each layer of wire a layer of insulating material."

This Patent embraces some other considerable improvements, and a resistance box, constructed in strict accordance therewith, was shown in the Electrical Exhibition at Paris in 1881. It was also included in the exhibit of the Eastern Telegraph Company at the Crystal Palace in 1882, and I still have it in almost daily use. An illustrated description of this box will be found in *Engineering*, July 28, 1882, pages 79 and 80. Since then we have made several such boxes which give greater satisfaction, and stand this climate far better than boxes made in England in the old way.—Yours, &c., J. Clement Cuff.

Eastern Extension Telegraph Company, Singapore,
January 1, 1891.

## CONDUCTIVITY OF STRANDED WIRE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Referring to your review of Mr. W. S. Boult's wire-table and the question raised in it regarding the comparative conductivity of strands, I have always found them to be of lower resistance than that of the single wire divided by the number of strands, but hitherto have not considered the exact difference.

To test the point, I have made about 190 yards of 7/20 out of one coil of wire with a special short lay in order to enhance the difference, if any, and measured an equal length of single wire off the same coil in order that no question of conductivity or diameter might enter into the question.

The resistance of these two were balanced carefully against one another by a modified form of Wheatstone Bridge. The resistances were found to be in the proportion of 1 : 7·052. The weights, both by actual weighing and by calculation, were as 1 : 7·142.

You will see from this that the resistance is approximately midway between that of seven straight wires and that calculated from the actual weight. I expect in a 19 or 37 strand the conductivity will be much nearer the proportion of the actual weight, as the wires touch at so many points in crossing one another.

The average weights of strands for ordinary telegraph and electric light work, as made by our firm, are about 7·07, 19·35, and 37·9 times the weight of the single wire for 7, 19, and 37 strands respectively, and these may be taken as good averages for most makers.

Hoping the above may prove of interest.—Yours, &c.,
James Connolly,
Electrician to the Okonite Company.

Newton Electric Works, Newton Heath, Manchester,
February 3, 1891.

# TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

Tenders Wanted.—It will be seen by our advertisement columns that tenders are invited for providing and fixing the engine and all necessary plant and appliances complete for lighting the Ipswich Borough Lunatic Asylum by electricity. The premises can be viewed, and further particulars obtained, on application to the Medical Superintendent at the Asylum. Tenders, endorsed "Tender for Electric Lighting," are to be sent to the Chairman of the Committee, at the Asylum, before March 1 next.

Mr. Crompton's Laboratory.—We learn that this laboratory is now complete and fitted with modern electrical appliances. Tests can be made and reports given upon conductivity of copper and magnetic qualities of iron and steel, insulation resistance of various materials used for covering electric conductors and other purposes, arc light carbons, quantitative tests of accumulators, calibration of direct current indicators to 3,000 amperes, calibration of direct current potential indicators to 2,000 volts, certification of registering or coulomb meters. In addition to the above, photometric and other tests can be made.

Humboldt Electric Power and Mining Company (Limited).—At a meeting of this Company, held on the 14th inst., a resolution passed at a previous meeting that the Company be wound up, and that Mr. W. F. Gardner, the secretary, be the liquidator, was confirmed.

Electric Light Installation near Ascot.—Sunningdale Park, near Ascot, which has recently been acquired by Major Joicey, is to be electrically lighted throughout. It is estimated that about 350 lamps will be required to light the house and stables, and the generating plant will comprise two "Cornish" boilers and two "Parsons" steam turbine dynamo machines of the new improved type. The installation is being arranged by Mr. A. A. Campbell Swinton.

Messrs. Blakey, Emmott and Company (Limited).—We have received from this firm their newly issued illustrated catalogue and price list, giving full particulars of the Blakey-Emmott continuous current, and the Blakey-Emmott alternating current dynamos, the B.E. transformer, their special engine and dynamo combination, and the various specialities manufactured by the firm, including main and branch switches and fuses, lamp holders, measuring instruments, &c. Illustrated particulars are also given of the Blakey-Emmott diferential arc lamp, and of complete lighting sets for dyers, &c. Not the least conspicuous illustration is that of the Company's large works at Halifax.

Jensen Electric Bell and Signal Company.—We have received from this Company a number of advanced sheets of a new catalogue in preparation, giving illustrated particulars and prices of the firm's various manufactures, including the Jensen electric church bell, indicators, &c., and also of Lacombe's patent central zinc battery. Several handy sets of bells, batteries, &c., are shown.

Stone Discs for Switch Bases.—We have received from Messrs. F. A. Richter and Company some excellent samples of stone discs, bases, &c., made from their patented material "real stone." They are made with great accuracy and care, and compare favourably with similar articles made from earthenware, porcelain, &c. They appear to be porous, but would doubtless be very easily saturated with insulating material.

Mills Sectional Steam Boiler.—We have not yet been convinced of the complete superiority of water-tube boilers over the old-fashioned Lancashire which are so popular among electrical engineers, but there are doubtless many situations for which they are very well adapted. Those who intend to put down a water-tube boiler should carefully examine the merits of the Mills Patent Excelsior Boiler, which claims a very remarkable economy, and supports its claims by the results of tests made by Mr. Longridge. The chief feature is a cylindrical water-cased furnace. The arrangement may be briefly described as a miniature Cornish boiler inside a Babcock Wilcox.

# BOOKS, &c., RECEIVED.

"Journal of the Institution of Electrical Engineers," Vol. XIX., No. 90. (London: E. and F. N. Spon.)

"Directory of Technical Literature." Edited by Fritz von Szczepanski. (London: Sampson, Marston, Searle, and Rivington.)

"Theoretische und Praktische Untersuchungen zur Konstruktion Magnetischer Matchinen." By Dr. Max Corsepius. (Berlin: Julius Springer. Munich: R. Oldenbourg.)

"An Explanation of the Phonopore." By C. Langdon-Davies. (London: Kegan Paul, Trench, Trübner and Company.)

# PATENT RECORD.

## APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

December 16, 1890.

20,493. J. P. BAYLY. London. Improvements in connectors applicable to joining electrical or other wires, or for any similar purpose. (R. T. Moore, Ceylon.)

20,510. H. H. LAKE. London. Improvements in apparatus, chiefly designed for reducing the burr on electrically welded metal articles. (W. M. Wood, United States.)

20,538. A. J. BOULT. London. Improvements in or relating to electric lamps. (D. Tommasi, France.)

20,540. W. P. THOMPSON. Liverpool. Improvements in welding metals electrically. (C. L. Coffin, United States.)

20,541. W. LE GRAND BURDY. Liverpool. Improvements in and relating to electrically actuated cash drawers or registers.

December 17, 1890.

20,571. A. McDONALD, J. P. McDONALD, J. C. and J. McDONALD. Manchester. Improvements in the arrangement and simplifying the mechanism of an electrically controlled arc lamp.

20,612. W. WHITE. London. Improvements in socket holders for incandescent electric lamps.

20,632. S. O. COWPER-COLES. London. Improvements relating to the manufacture and coating of metallic articles by electro-deposition, and to apparatus therefor.

20,639. C. LE BLON, A. OBLASSER, and A. GODDYN. London. Improvements in and relating to electric arc lamps.

December 18, 1890.

20,651. Sir H. C. MANCE. Bedford. An improvement in electrical transformers.

20,712. E. ORTELLI. London. Improvements in and relating to electric batteries.

December 19, 1890.

20,743. W. J. FARR. Reading. An automatic releasing and electrical resetting signal.

December 20, 1890.

20,784. W. J. ENGLEDUE. London. Improvements in metallic elements for galvanic batteries.

20,817. C. VAN DER ELST and B. LOEWENSTEIN. London. New or improved means (dynamo multiplex) for utilising the centrifugal or projecting force of a rotary body.

20,821. F. G. COMING. London. Apparatus for transferring electric car batteries. [Date applied for under Patents Act, 1883, Section 103, May 21, 1890, being date of application in United States.]

20,830. H. BAYLEY. London. Improvements in and connected with electric ceiling roses and electric wall connectors.

20,831. W. H. OAKLEY and C. E. SPURRIER, London. Improvements in electric ceiling roses and wall connectors.

20,838. H. BIRKBECK, London. A new or improved dry couple or element for electrical purposes. (O. Henrichsen.)

December 22, 1890.

20,896. A. GAY and R. HAMMOND. London. Improvements in apparatus for regulating electric currents or electric potential.

20,898. H. H. LEIGH. London. Improvements in dynamo-electric machines. (E. Léon Desroziers, France.)

December 23, 1890.

19,272A. C. E. CARPENTER. London. Improvements in electric soldering irons. [Date applied for under Patents Act, 1883, Sec. 103, June 21, 1890, being date of application in United States.] [This application having been originally included in No. 19,272, dated November 26, 1890, takes under Patents Rule 23, that date.]

20,927. H. G. LESTER. London. Improved insulated circular cut-out box for electric lighting.

20,940. W. H. BECK. London. Improvements in electrical indicating apparatus for range or location-finding instruments. (The American Range Finder Company, United States.)

20,983. M. H. HURRELL. London. Improvements in electrically-controlled long-range torpedoes.

20,986. H. H. LAKE. London. Improvements in apparatus for electrically welding, and otherwise working metals. (H. Lemp, United States.)

20,992. G. H. JONES. London. Improvements in electric bells.

December 24, 1890.

21,017. F. PROTZ and J. JUCKER. Manchester. Improvements in electric arc lamps.

21,026. A. W. BERNE and C. A. FISH. Liverpool. Improvements in electrical attachments for railway switches or points, applicable for ringing an audible signal on the locomotive of a train which is approaching a switch which has been misplaced.

21,031. P. J. DAVIES. London. Improvements in the production of lead plates or electrodes for secondary batteries and the connection straps or lugs to the same.

21,032. W. W. HORN. London. Improvements in covering and protecting electric wires and other conductors. (W. E. Oehrle, United States.)

21,045. F. WALTON. London. Apparatus for armouring insulated electrical conductors.

December 27, 1890.

21,116. A. GAY and R. HAMMOND. London. Improvements in electric arc lamps.

December 29, 1890.

21,142. O. Y. RHODES. Halifax. Improvements in miners' safety lamps, and in the method of lighting the wick thereof by an electric current.

21,143. O. Y. RHODES. Halifax. Improvements in electric batteries for lighting miners' safety lamps.

21,147. A. J. BOULT. London. Improvements in or relating to the insulation of electrical conductors. (J. B. F. Frédureau, France.)

December 30, 1890.

21,183. B. J. B. MILLS. London. Electric protective and signal systems and apparatus. (C. E. Ongley. United States.)

December 31, 1890.

21,254. MORRIS BROTHERS, Limited, Birmingham. Measuring electromotive force and current of electricity in one instrument.

21,301. J. G. MURDAY. London. An electrical signalling device for indicating the overheating of journals, bearings, and other parts of machinery; also applicable as a fire alarm, and for indicating the rise and fall of temperature in greenhouses, buildings, and for similar purposes.

January 1, 1891.

40. G. HOOKHAM. Birmingham. Improvements in electricity meters.

49. W. WENSKY. London. Element and process for producing constant electric currents.

January 2, 1891.

83. W. P. THOMPSON. Liverpool. Improvements in or relating to electric guest calls or the like. (A. Striemer, United States.)

100. W. C. JOHNSON and S. E. PHILLIPS. London. Improvements in suspension insulators for electrical conductors and electrical apparatus.

105. F. HASELWANDER. London. Improvements in lightning arresters for electric conductors.

January 3, 1891.

128. J. L. LEE. London. An improved means of and apparatus for regulating automatically the flow of electric currents.

January 5, 1891.

176. W. J. GARNETT. Bradford. Improvements in electric dynamos and motors.

184. R. E. B. CROMPTON. London. Improvements in dynamo machines.

185. R. E. B. CROMPTON. London. Improvements in dynamo machines.

200. L. BRIANNE. London. Improvements in or connected with electric arc lamps.

January 6, 1891.

223. W. H. TODD. Manchester. Improvements in primary electrical batteries.

230. F. SCHWARTZ. London. Improved mechanism for actuating clocks by electricity.

244. C. HARRISON. London. A wire guard for electric lamps.

248. F. G. CORNING. London. Improvements in mechanism for transferring electric car batteries. [Date applied for under Patents Act, 1883, Section 103, June 9, 1890, being date of application in United States.]

258. A. GAY and R. HAMMOND. London. Improvements in electric arc lamps.

271. A. SCHENERSTEDT. London. Improvements connected with electric arc lamps.

284. E. L. MAYER. London. A new or improved telephone transmitter.

285. E. L. MAYER. London. A new or improved method of telephonic transmission and apparatus therefor.

January 7, 1891.

303. C. K. HARDING. London. Improvements in electric railway systems. [Date applied for under Patents Act, 1883, Section 103, June 9, 1890, being date of application in United States.]

January 8, 1891.

361. F. W. WEBB and A. M. THOMPSON. Crewe. Improvements in dynamo electric machines.

389. F. TEAGUE. London. Improvements in electricity meters.

394. W. T. GOOLDEN and S. EVERSHED. London. Improvements in electric measuring instruments.

January 9, 1891.

439. B. J. B. MILLS. London. Improvements in torpedoes propelled and steered by electricity. (W. S. Sims, United States.)

January 10, 1891.

475. A. E. D. WALTERS. Southsea. The absolute silence of telephone telegraph, and other wires, whether attached to chimneys buildings, iron standards on roofs, or wooden poles placed in any position.

476. W. E. BANTA. Glasgow. Wire coupling for electrical conductors. [Date applied for under Patents Act, 1883, Section 103, June 11, 1890, being date of application in United States.]

Digitized by Google

490. S. A. ROSENTHAL and W. SMETHURST. London. Improvements in the construction of electric batteries for application to the firing of fire-arms and other explosive appliances.

492. R. WILLIAMSON. London. A jointed bracket for electric lamps.

508. W. H. MUNNS. London. An improved underground electric conduit. (H. Young, United States.)

536. C. W. ATKINSON and L. B. ATKINSON. London. Improvements in dynamo electric generators and motors.

January 12, 1891.

573. W. J. RUNDLE, F. B. LEA, and A. G. NEW. London. Improvements in devices for hanging pictures, especially applicable to the casing of electrical conductors.

584. M. HAUTIN and M. LEBLANC. London. An improved construction of alternate current dynamo electric motors.

587. F. H. P. BERLYN. London. Improvements in or connected with incandescent electric lamps.

593. T. COAD, London. Improvements in electric primary batteries.

January 13, 1891.

608. I. PARKER. Wolverhampton. Improvements in construction of channels for the use of electric conductors in streets.

616. H. J. ALLISON. London. An improved carbon stick or pencil for arc lamps. (B. B. Ward, United States.)

617. H. J. ALLISON. London. Improvements in the construction of electric arc lamps, and appliances used therefor. (B. B. Ward, United States.)

624. AMERICAN ELEVATOR COMPANY. London. Improvements in Electrical elevator apparatus. (Otis Bros. & Co., United States.)

641. E. G. HAMMER. London. Improvements in electric clocks.

647. H. H. LAKE. London. Improvements in electrical measuring instruments. (E. Weston, United States.)

649. H. H. LAKE. London. Improvements in and relating to electric elevators or lifts. (R. Eickemeyer, United States.)

657. H. H. LAKE. London. Improvements in conduits for electric conductors. (A. Lord, United States.)

667. W. P. THOMPSON. Liverpool. Improvements in electrodes for voltaic accumulators. (The Hess Electric Storage Battery Company, United States.)

668. W. P. THOMPSON. Liverpool. Improvements in or appertaining to voltaic accumulators. (The Hess Electric Storage Battery Company, United States.)

669. J. PULUJ. London. Improvements in electrical cut-outs or safety fuses.

January 16, 1891.

846. W. V. MORTEN. London. Improvements in electrical cables.

January 17, 1891.

860. A. H. BAGNOLD. Rochester. An electric bell repeater. An electric bell and receiver for electric signals.

861. G. L. ANDERS and C. H. ELLIOT. London. Improvements in the insulation of metals for electrical purposes.

## SPECIFICATIONS PUBLISHED.

1889.

20,974. VAN RYSSELBERGHE. Electric Supply. (Price 8d.)

1890.

135. ATKINSON. Alternate current motors. (Price 8d.)

1,246. FITZGERALD and FALCONER. Electrolytic generation of chlorine, &c. (Price 4d.)

2,241. ROBINSON. Electric vote indicator, &c. (Price 8d.)

2,527. CORNWELL. Electric arc lamps. (Price 8d.)

3,133. BOARDMAN. Incandescent arc electric lamps. (Price 8d.)

3,163. ALEXANDER. Electric switches. (Price 6d.)

4,000. PIEPER. Electric regulators. (Price 8d.)

4,028. FITZGERALD. Electric telephone transmitters. (Price 6d.)

7,044. LAKE (Brooks). Electric conductors. (Price 6d.)

7,186. THOMPSON (Coffin). Welding metals electrically. (Price 6d.)

9,668. HEBENDAHL and Others. Elevating, &c., electric lights. (Price 6d.)

9,797. ALEXANDER. Electric circuit controlling apparatus. (Price 8d.)

10,122. DEWEY. Electric railways. (Price 8d.)

12,997. BRAIN and Others. Electrical rock drill, &c. (Price 6d.)

13,009. ODELL. Printing telegraphs. (Price 1s. 1d.)

13,362. EDWARDS (Cassalette and Another.) Automatic telegraphs. (Price 1s. 6d.)

14,634. INGLEFIELD. Electric light signalling. (Price 6d.)

15,043. LAKE (Abshagen). Electric heating apparatus. (Price 8d.)

15,084. VAN DEPOELE. Electric railway conduits. (Price 8d.)

16,346. CURRIE. Distributing electricity by storage batteries. (Price 8d.)

18,292. DRAKE and GORHAM. Electrical switches. (Price 6d.)

18,576. NEVILE. Controlling electric currents. (Price 8d.)

18,625. LAKE (Lemp). Electric welding, &c. (Price 8d.)

18,631. LAKE (Thomson). Welding metals by electricity. (Price 6d.)

19,057. THOMPSON BEACH. Electric Arc Lamps. (Price 6d.)

19,097. CLARK (BORNHOLDT & GLATZ). Incandescent Electric Lamps. (Price 6d.)

19,162. DEWEY. Electric welding and metal working. (Price 8d.)

# COMPANIES' MEETINGS & REPORTS.

## The Anglo-American Telegraph Company (Limited).

The ordinary half-yearly meeting of the proprietors in this Company was held at Winchester House, Old Broad-street, on the 30th ult., under the presidency of the Marquis of Tweeddale.

The SECRETARY (Mr. T. H. Wells) having read the notice convening the meeting, the report of the Directors, which has been published in *The Electrician*, was taken as read.

The CHAIRMAN: Gentlemen, in the first place I desire to refer to the loss which the Company has sustained through the resignation of our chairman, Lord Monck. Lord Monck joined this Company in the position of Chairman seventeen years ago. He brought to bear on our deliberations great knowledge of business and public affairs. He was a very good man of business himself, and he won from the first and retained to the last the regard and confidence of his colleagues, of the officials of the Company, and, I think, of every member of the proprietary. No one who remembers Lord Monck in the chair can have forgotten the dignity and uniform courtesy with which he conducted the affairs of the meetings. I ask you to join in a cordial expression and wish that he may long live to enjoy the repose which a long, active, and useful life renders him so worthy of. I believe that the manner in which the vacancy on the Board caused by his resignation has been filled will meet with the approval of everyone present. We believe that in appointing Sir Albert I. Leppoc Cappel as one of our Directors, we have chosen the best man we could get. The distinguished career he led in India, crowned by occupying the highest position in connection with the telegraphs in that country, both submarine and land, and the honour which was bestowed upon him on retiring from the service, offer, I think, ample evidence that he will be a valuable acquisition to our Company. With regard to the honour which has been done to me by my colleagues, I shall not say a word more than that if you renew your confidence in me later on I shall do my very best to justify the position which my colleagues have been good enough to bestow upon me. Turning now to the accounts and the report, you will observe that the gross receipts have amounted to £161,986, and that the total expenses were £56,142. The gross receipts are somewhat larger than they were this time last year, and the total expenses are somewhat less. For instance, the traffic receipts show an increase of £3,027, and the total expenses show a decrease of £2,470. We had a sort of windfall in the shape of the hire of the "Minia," which enables us to add £1,500 to our receipts, and we carry forward rather less than we brought forward from last year. These sums added together enable us to recommend the payment of a dividend somewhat in excess of what was paid last year; that is to say, we recommend a dividend of ½ per cent. more than we had last year, making £2. 17s. 6d. for the whole year. I think the reduction in the total expenses must be regarded as a highly satisfactory feature, because you find that under the heads, both of repairs and renewals of cables there is a very large decrease as compared with last year. The ordinary repairs are less by £6,919, whilst almost the whole of the interest on the renewal fund is appropriated to increasing that fund, which now amounts to £980,000, and if we chose to add the increased value of our securities over their cost price we should raise this amount to something over a million. The working expenses, under Tables B and C, are higher than they were at this time last year by £4,449. This increase is mainly due to the offices which we found it desirable to open in New York and other places of a less important character, and agencies which have been established in other parts. You are aware that we are exposed to a very active competition for the traffic between this country and the United States, and when the competition takes the shape of establishing offices in different parts of the United States, of this country, and abroad, it becomes indispensably necessary to pursue the same policy. It is proved beyond doubt that if any company establishes an office in any particular town the traffic goes to that company, so that if we wish to maintain our present traffic and improve it, we must at least do what our competitors are doing. I dwell upon this because I think it is not impossible that the increase to which I have just referred may be further increased during the present half-year. The increase in our traffic does not appear to be a very large figure, but it is an increase on a very considerable increase at this time last year. The increase then amounted to something like £23,000, so it is not, from that point of view, so insignificant as it might appear. At the same time we all admit on this side of the table that we should be very glad if that increase had been larger. We should have been very glad to have obtained a larger share of the traffic between this country and the other side, but I do not think we can lay to ourselves any blame for not having done our best to increase that share. What we have to do is to render our service as efficient as possible. I believe when our lines are in order we are unrivalled with respect to regularity and speed; but there are times when we are exposed to interruptions on our land lines both on this side and the other through the storms which prevail in the winter months, and these interruptions are a source of annoyance to ourselves and to those who favour us with their traffic. With regard to these interruptions, I may say they are far more numerous on the other side than on this, and we have been for some time endeavouring to find a remedy for this drawback to our system. I hope before we meet you again to be able to report to you that the interruptions on the other side have become less, and that the means we hope to adopt to reduce them will have been carried into effect. Although, no doubt, causes operate in favour of certain lines, apart from the efficiency of those lines, I think we may lay it down as a general maxim that in the long run the traffic will flow over the lines where the service is

Digitized by Google

best performed, and, therefore, I hope we may look forward in the future to an improved traffic—an improvement which has existed during the last six months, and which I hope will characterise the current six months. There is one other matter to which I must refer, and that is with regard to the position of our lawsuit in Paris. It was suggested at the meeting the other day of the Direct Cable Company that we had not been as active as we might have been in seeing that this suit was carried to a conclusion. I do not think that there is any justification for such an idea. The suit was instituted in 1886, and the first decision, a judgment in our favour, was given on January 9, 1888. The judgment was appealed against, and on March 19, 1889, a judgment adverse to us was given. We lodged our appeal with the Conseil d'Etat on July 3, 1889, and on March 28, 1890, the French company's defence was entered. The record of the case has been before the Conseil d'Etat in various shapes ever since that time, and we are informed that in all probability it will come up for judgment within a reasonable time. It has not been put on the roll yet, but the moment it is, we understand there will be no delay in the hearing and judgment. I think I have touched upon all the more important matters referred to in the report, and I shall conclude by moving the adoption of the report of the Directors and accompanying statement of accounts to December 31, 1890, and the payment of the dividends as recommended in the report.

Sir JAMES ANDERSON seconded the motion.

The CHAIRMAN then expressed his readiness to answer any question, or to supply any information that might be required.

Mr. WREFORD said he did not desire in any way to oppose the motion, but perhaps the Chairman would be good enough to let them know whether any "crumb of comfort" could be offered to the Deferred shareholders, of whom he was one. They had waited for a considerable time, and with patience, in the hope that they might have some dividend; and he had taken note of what the Chairman had said—that if the increased value of the securities they held was taken into account there would be over £1,000,000 at the credit of the renewal account. This being so, did it not occur to the Directors that some portion of the benefit arising from the renewal fund might be divided among the Deferred shareholders?

Mr. LEON: Mr. Chairman and fellow-shareholders, I have no resolution to propose, but I should like to offer a few remarks, in quite a friendly way, not in any hostile spirit, but with the ordinary authority of a large moneyed interest in the Company, and with the knowledge I possess in being one of the largest customers of this Company. I think, gentlemen, that we have very little reason to congratulate ourselves upon the working of this Company for the last year, and I will give you several reasons for this statement. First of all, our worthy Chairman remarked that we are unrivalled as regards regularity and speed. I may say, gentlemen, that my experience as a very large customer is quite the contrary.

The CHAIRMAN: Allow me to say that I refer to the lines when not interrupted.

Mr. LEON: When there is no interruption; gentlemen, our worthy Chairman is quite correct. I want to lay down as an axiom, gentlemen, that the interest to be paid to the stockholders depends very much on the attention paid by the management to the customers, and owing to this very strong competitive element that we have to face—I allude to the Commercial Company—the individual customer—my custom, for example—is of much more importance to this company than this company is to me, for at any moment I can move, and get another very large customer to move off bag and baggage to the enemy. I do not want to do this, gentlemen, because I have a very large moneyed interest in this concern. I don't want to make any idle threat as to what we should do, but I only want to diagnose the disease that is rapidly spreading in the management of this Company. I hear on good authority that the Commercial Cable has opened offices in Dundee and Bradford, and probably in other places. I want to know, Mr. Chairman, from those who have the management of these details, why we did not do the same. You must know that my business is on the Stock Exchange, and it is of the very greatest importance to me that my messages are received and despatched very promptly. We employ the Anglo-American Company to carry our messages for New York, and if we do not get these messages delivered immediately our business is absolutely worthless. In the management of my business I stand on the Stock Exchange, and my clerk has a seat in the office of this Company in Throgmorton-street, and he sends me the price of stocks from New York, and also any remarks he may have to make as to the working of the cable. These remarks are by no means of a satisfactory character, and I do not think there can be any difference of opinion about that. Now, I believe I have diagnosed the disease. The question is, gentlemen, to find out the remedy. As I said before, I do not speak in any way hostile to this Company; I am only speaking for the benefit of the stockholders, and also for benefiting indirectly their customers. I ask you, therefore, Mr. Chairman, whether it is not advisable to spend some of our large reserve fund in doing away entirely with land lines, and laying a direct cable, in direct opposition to the Commercial Company, right up the Hudson River to New York; then, also, in opening offices where the Commercial open them, and even in some of the numerous places where the Commercial have not opened them, so that we may now enter into active competition, not in the way of a decrease in the rates, which is a bad way of competing for both sides, but by giving, if possible, more facilities to the public, so that they may prefer our cables to those of our opponents. I have nothing more to say, sir, except I believe that if this is not done by the Company, my friends—that is, myself and another large firm, I won't mention their names—will leave altogether; and I may tell you more, that we believe that if you lose our custom it means something like a ¼ to ⅜ per cent. on the dividend of the entire Anglo stock. I have the figures here, and they will show you the amount of money we spend in one year in cabling alone to New York. I believe it will also affect the proprietary, because the stockholders will enter into a canvass of the members to put new blood on the Board. I do not mean to say that new blood is absolutely necessary, but it is advisable, after a course of years, to change the blood of every organisation and public company. That is all I have to say, and I should like to hear any remarks you may make as to what is to take place in the coming year as regards an improvement in the management of the Company.

Mr. WOOD inquired whether, if the lawsuit about which they had heard did not come on for hearing in a short time, the Directors could do nothing to expedite the matter. Many of the shareholders were getting rather tired of seeing that the lawsuit was still pending. There seemed to be no end to it; and was it possible that it was being put off for a set purpose?

Mr. JACKSON said he believed that he was expressing the general opinion of the proprietors when he said he agreed with the eloquent eulogium which the Chairman had bestowed upon Viscount Monck. He was sure that those who had been attending the meetings of this Company would agree with everything that the Chairman had said respecting Lord Monck, and would join in the hope that their late Chairman might be spared for many years to enjoy his retirement. He had no doubt that Lord Monck regretted as much as they themselves did the low state comparatively into which the Company had fallen. He said "comparatively," because he remembered when they paid handsome, but in no sense excessive dividends, considering their risks. He thought that these risks had been well illustrated by the gentleman who had brought a sort of charge against the Company by showing how frequently their communication was interrupted. He wished that he could feel confidence and hope in what the Chairman had told them about the little increase paid on the present occasion in their dividend, but he was afraid that it was owing more to the immunity which they had enjoyed from accidents than to an increase in their traffic. The Chairman had pointed out that they had had an increase of revenue of £3,000, and that their expenses had shown a decrease, but they did not show a decrease.

The CHAIRMAN: Not the working expenses, but the total expenses.

Mr. JACKSON, continuing, said that the expenses did not show a decrease in the essential direction. The decrease was owing to the smaller amount of damages to the cables. The absolute increase in the working expenses compared with those for 1889 was more than the difference in their income. The working expenses at the head office and at the stations—the permanent working expenses—were £39,300 in the December half of 1889, while in the half-year under review they had amounted to £43,700, owing, as has been said, to the establishment of offices in New York and elsewhere. With reference to Mr. Leon's remarks they might be met with the answer that if he depended entirely on the two cables of the Commercial Company he might suffer still greater inconvenience from interruptions, owing to the amount of business passed over those lines, than he had been subjected to by using this Company's cables. There were something like seven "pool" cables, and it was inconceivable that these seven cables could not do the work more satisfactorily than the other two. He did not know whether Mr. Leon referred to the Direct and the other associated Companies; but surely seven cables must be more reliable than the two of the Commercial Company. However, this was a matter for the Manager to reply to. They knew that they had gentlemen conducting their business who had extraordinary ability, great experience, and unequal knowledge which had been acquired over a long period of years; and he would merely impress upon Mr. Leon, before he withdrew his custom, that he would probably find that he would suffer more inconvenience in his business than he would if he continued to employ the "pool" cables. He regretted, and he was sure the Directors regretted, the poor return of profit now obtained by the Company. He knew that competition was put forward as explaining this; but it was no answer to the gravamen of his charge. He thought that the Board, as Mr. Leon had said, did require an infusion of "new blood" in some sense. One of the highest authorites on telegraphy observed lately that it was a question of "new brooms." He did not know whether the authority meant it to be inferred that the "old brooms" were worn out when he said that the cleverest man would win. Mr. Leon's remarks ought certainly to be taken to heart, because he (Mr. Jackson) maintained that there was great dissatisfaction at the absence of anything like real improvement in the Company. With regard to the appointment of the new Chairman, he desired to speak with every possible respect of Lord Tweeddale's great knowledge, business experience, and high character; but he desired to express his opinion—he meant nothing in the way of offence—that a protest was due from the shareholders' side of the table against the practice of pluralism of directorships. How could they hope to get out of their difficulties arising from the state of stagnation which had come over their affairs when, notwithstanding his great abilities, they had a Chairman who was a member of the Board of 16 different companies, of several of which he was the head, including the North British Railway Company? He hoped in any case that their Chairman would do what he could to introduce an element into the Company which would prove beneficial to them, and he trusted that the views which he had just expressed would receive the honest, unbiassed support of other shareholders. With the fact that the last competitor who had come into the market to do business was paying a dividend of 7 per cent., and putting by 5 per cent. or 6 per cent. to redeem debentures—that was to say, earning 12 per cent., he thought the shareholders of this Company were entitled to ask why they were not in a better position.

Mr. HUMPHREYS said with regard to 40 per cent. of the capital of the Company, the Deferred, the holders of which were receiving no dividend, they were an important body, holding, as they did, £2,800,000 of the capital. They were receiving nothing, and yet another section of the proprietors was receiving 5½ per cent. In these days of conversion, which seemed to him to be all the fashion, he would like to ask

Digitized by Google

why the Directors had not given consideration to this subject, when he thought the holders of the large amount of capital which he had mentioned would receive some return. Their reserve fund now amounted to £980,000, and a portion of the current half-year's interest derivable from the investments would complete that sum up to £1,000,000. He asked, in justice to the long suffering, patient, and very quiescent holders of 40 per cent. of the capital, might they not have the interest earned by the reserve fund appropriated to their benefit in the coming half year? He hoped, with the changes which had occurred on the Board, that the Directors would apply their energies to considering the Deferred shareholders of the Company. Let them, either by conversion or by purchase, or by some other means, get rid of the Six per Cent. Preference Stock.

The CHAIRMAN, in reply, said Mr. Wreford asked me if we could hold out any hope on this side of the table for the Deferred shareholders. That is a very delicate subject, and involves the question of dealing with the renewal fund. It has always been in my mind that £1,000,000 was the very least we should have standing at our credit, having regard to the age and condition of our cables, and the necessity some day or other of renewing them. At the same time if we were to go on putting by as much as we have done during the past year to the reserve fund, I have no doubt that the Directors would then take into consideration the possibility of placing less to the renewal fund. This last year we added to that fund £27,894 out of interest, which amounted to about £31,500. Now, if we could hope to go on at that rate for a year or two more, I have no doubt that the matter would be open to consideration. Beyond that it is impossible for me to go, and I am saying even that only as my own personal opinion. I must acknowledge the reasonable spirit in which Mr. Leon spoke. His grievance is a perfectly legitimate one. He is a large holder of our stock, and a very excellent customer. I am glad to be able to say, with respect to one of his criticisms, that we have given orders for offices to be opened at two of the places he named—Bradford and Dundee—and that we contemplate establishing offices in several other places where we are likely to obtain custom which will repay us for so doing. I said that he has a legitimate grievance, and I think that the remarks which fell from me in proposing the adoption of the report must have convinced him that the grievance is one that is attracting our serious attention. I have no doubt that the cure will be the one suggested by Mr. Leon, which is perhaps the only cure—the substitution of submarine for land lines. We are, however, of opinion that the land lines might be more carefully looked after than they are at present, and we found that opinion upon the fact that our own lines in this country and other places, where we have them exposed almost as much, if not quite as much, as are those of the Western Union, are rarely interrupted. From that we conclude that the same amount of vigilance which is exercised on this side, if exercised on the other, would very largely reduce the number of interruptions on the land lines. I may, however, tell Mr. Leon that we have before us the question, if not altogether of running a cable into New York, as he suggested, of coming to some arrangement by which we should have an uninterrupted cable communication with New York. I suppose Mr. Leon will be quite satisfied with that if we can bring it about. What I said with regard to the unrivalled speed with which our business is done when interruptions were not taking place owing to the weather is, I believe, strictly and literally true—that no company comes near us with respect to the rapidity and despatch of our cables. I should have no difficulty in submitting data which would satisfy all present as to the truth of that statement. Mr. Jackson, who followed Mr. Leon, referred to the expenditure, and said it was larger than the corresponding increase in the receipts had been. That may be true, but it does not in any way justify any adverse criticism upon the expenditure which we have incurred in establishing offices, &c., because if we had not established those offices we might ask whether we should not have been worse off than we are now. The New York office, which was established a short time ago at considerable expense, has entirely justified our expectations. Then Mr. Jackson complained of the small amount of our receipts, and he told us that competition is no answer as explaining it. But surely competition is the whole answer. If we had enjoyed anything like a monopoly—a semi-monopoly, which it is said we enjoy to the East—a very different state of things would be realised. Mr. Jackson knows very well that not only is this traffic free to competition, but competition of the most remarkable character—competition by private individuals, not even by a Company. Surely that is the real answer. As long as that is the case, the property of this Company is and must be regarded as of more or less precarious character. Then Mr. Jackson did what he was perfectly entitled to—criticised the Directors in having appointed me as their Chairman; and he denounced what he described as pluralism. He is perfectly entitled to his opinion on that matter. I can only say for myself that I have never sought for any one of the positions which I hold. I have been invited to occupy similar positions with a great number of other institutions which I have declined; and I may say that the particular business to which he referred only forms a very small part of the work which I discharge in the course of the year. As to his suggestion that I have too many engagements to do my work properly, I may point out that only recently I was asked to be in my own country what corresponds in this country to the Chairmanship of the County Council. Everybody knew how much I was occupied, but notwithstanding that this position was offered to me, and I accepted it. There must be some reason for this—I do not wish to say much on the point—but there must be some reason why I should be invited to occupy the position which I have the honour to fill to-day. Mr. Humphreys, I think, suggested that some alteration should be made in the constitution of the Company. If Mr. Humphreys will submit any scheme which he thinks is likely to be adopted by his brother shareholders, we should be very glad to consider it. He also suggested that our stock might be bought, but we have no power to do so; nor could we do anything with respect to a dividend on the Deferred stock until the Preferred stockholders have had their dividend in full. There is one remark I see I have omitted to make with respect to Mr. Leon's complaint. I do not remember whether he referred to it, but I wish to point out to him that our Companies were the only ones which carried the traffic during part of the day on which the great storm occurred in America. Mr. Wood wished for further information with respect to the lawsuit. If you will let me, I will read the last part of the report which has been drawn up with respect to that suit, as it will put him in possession of all the information which can be afforded him.

A SHAREHOLDER: Could you say what is the amount involved?

The CHAIRMAN: Oh, it is a very considerable sum. I may repeat that in July, 1889, this Company lodged its appeal to the Council of State, and that on March 28, 1890, the French Company's defence was entered; and now I may read this extract from the report which I have just referred to: "Since then we have several times communicated with Paris, but have been unable to ascertain when the appeal can be heard. It appears that the Council of State, besides the ordinary legal business, has to decide contested elections and questions arising with certain public bodies. When the papers are completed they have to be submitted for examination to the advocates of both sides, and also to the Minister within whose department the matter lies. This stage was reached long ago. Next, the papers have to be sent back to the Council of State, and put into the hands of the Master of Requests, who sends to the contentious section of the Council a report, which is examined and discussed in secret. We understand the office of the Master of Requests is overwhelmed with business, and that each case has to come in turn. When the Master's report is completed it goes with the papers into the hands of the Commissary of the Government, who, after examination and approval, has the case entered on the roll. We have reason to suppose that the case will be soon put on the roll, but it is impossible to say more." I think, gentlemen, I have now replied to all the questions which were addressed to the Chairman, and I will therefore put the resolution which I have read to you, and which was seconded by Sir James Anderson. He then submitted the resolution in the usual way, and declared it carried unanimously.

Sir JAMES ANDERSON said that he had the next resolution to propose, but before doing so he desired to make one remark respecting the observations of Mr. Jackson and of his friend Mr. Leon. Those gentlemen had referred to "new blood" coming on to the Board. If, however, the shareholders would look around them they would see how many new faces there were, and how many of the old hands had dropped off. Nearly all the original Directors had passed away, and there were now on the Board four Directors who were not there a year ago—certainly not eighteen months ago. He, therefore, thought that there was "new blood" enough on the Board, unless they wanted the Directors to pass away a little faster. He then proposed the re-election of the Marquis of Tweeddale. After all that had been said about his lordship having so much to do, he could only tell the shareholders this, that there was no part of the whole business, from first to last, that did not enter into their Chairman's notice and that he did not have time to consider.

Mr. WILLIAM S. CUNARD briefly expressed his pleasure at seconding the resolution, which was carried unanimously.

The CHAIRMAN: I beg to return you my warm thanks for the confidence you have shown in re-electing me, and I hope I may be able to justify what you have done to-day. Continuing, he proposed the re-election as a Director of Mr. Cyrus W. Field, who, he said, had been connected with submarine telegraphy in the most honourable manner ever since it had existed.

Mr. CHARLES BURT, in seconding the resolution, observed that though they did not see Mr. Field much in this country, he was looking after their interests on the other side, and it was useful to have a man who would discharge this duty in New York.

The CHAIRMAN put the resolusion, and it was carried unanimously.

On the motion of Mr. JACKSON, seconded by Mr. HUMPHREYS, Mr. Joshua Dean and Mr. John Gane, F.C.A., were severally re-elected auditors of the Company.

The CHAIRMAN having intimated that this concluded the business,

Mr. JACKSON said he wished it to be clearly understood that he had the greatest respect for their noble Chairman, but had advocated what he thought was a business principle in the City of London. He had much pleasure in proposing a cordial vote of thanks to his lordship and his colleagues.

Mr. LEON, in seconding the motion, said that he would like to add a word more arising from what the Chairman had said, that their Company was now going to open offices at Bradford and Dundee. What he wished to say was, why were they not in advance of the Commercial Company? Why did not they open offices before the Commercial Company did, instead of "hanging on to their tails," and so carry on an active competition with such an important rival.

The motion was carried unanimously.

The CHAIRMAN having briefly replied, the proceedings terminated.

## City and South London Railway Company.

An extraordinary general meeting of the shareholders of this Company was held on Tuesday at the offices, 46, King William-street, E.C., to consider a Bill proposed to be introduced into Parliament to empower the Company to make an underground railway from the City to Islington. Mr. C. G. Mott presided.

The SECRETARY (Mr. H. H. M. Smith) having read the notice calling the meeting,

The SOLICITOR of the Company (Mr. Robert Fowler) briefly explained the main clauses of the Bill.

Digitized by Google

The CHAIRMAN: As regards the meeting to-day, it is simply called to consider the question whether we should or should not proceed with the Bill which has been introduced provisionally into the House of Parliament for the construction of an extension of this line from King William-street up to the Angel at Islington. It is not and has never been the desire of the Directors of this Company to proceed at all hastily with anything in connection with this line. We have been from time to time, during the years in which we have been constructing our line asked to go for various extensions, but except the small one at the Clapham end for which we obtained powers last year we have declined all such proposals up to the present time. Our desire was rather to consolidate this railway satisfactorily before we proceeded to extend it in any shape or form. That has been the view which the Directors took all along. We took it last year, and declined this very line that was proposed to us. The result was that we were threatened with another Bill which was proposed by the Central London, by which they were to occupy the ground which would have prevented this railway from being extended in the City of London. We must look to the fact that some of the best traffic for a railway such as this must ultimately come from the busy portions of the City. It did not appear to us a desirable thing that our road should be permanently blocked so that we could never go in for that traffic at any time, whatever might happen. On that account we thought it desirable and wise in your interests that this Session notice should be given for such a Bill as this, to allow us the right to go into the City at any time it would be desirable to go there. This line is one which I think can be carried out at comparatively small expense, and will go through one of the busiest parts that we could well have in the City. It is going straight up by the Bank, Moorgate-street, and the City-road. I think that the line in itself is a good one, and one that, so far as we can judge, will pay quite as well, perhaps better, than our existing line. The traffic is very large there, and the line would be a good one in itself. I would rather that the matter had been postponed, but it did not appear to us that it was safe in your interests that a postponement should take place, but we considered that we should occupy the ground at present and obtain the Act. As to the exact time of carrying it out, and as to the mode of doing it, that is, whether it is to be part of the capital of this line, or consist of a separate capital; these are matters which, if the Bill were obtained, the shareholders will have to decide for themselves at a later date. That is not the question before us at the present moment. We are here to decide whether it is desirable to go on with the Bill or not. That is really the position in which we stand. We should have postponed any further action in the matter if we could have done so safely, but we still think that it is most desirable in your interests that this Bill should, if possible, be obtained, and that it will be a very good line. The great object of a line of that kind I may tell you is this. As you know every morning and evening there is a very large rush of traffic, such as the line could take into and from the City, but during the middle of the day the trains are not by any means full. That is the experience of all the Metropolitan railways, and the great object of every one of these railways, in order to make good a dividend, is as far as possible to fill up the mid-day trains. The effect of another line such as this will be that we shall largely improve the mid-day traffic on the existing lines, and our existing line itself would improve the mid-day traffic on such a line as this. Therefore we should have a chance of a very much better dividend, I think, on our existing line if such a project were carried out. Whether we incorporate it as part of our own system, or make it an independent concern with a separate capital, is a matter which we can decide afterwards if we obtain powers. Upon all these grounds the Board are disposed to recommend you to go on with this Bill. The immediate effect of our proceeding has been that we have prevented the Central London from occupying the ground and blocking us out as they proposed to do last year. They have altered their Bill for the present, but if we leave the ground unoccupied it will be open for anyone to take possession of it. As regards our own railway, we have been only six weeks at work up to the present moment, and in a new line, and especially a new line such as this, there are a great many difficulties to contend with in working it, and giving a service which, as you know, is practically unexampled in the history of railways in this country. A rapid service such as we have started which we hope to still further develop, has never been attempted by any railway as a complete railway. There are small portions of the Metropolitan and District Railways where there is a train service similar to that which we now run, but no complete railway has run at the rate or the number of trains which this railway is doing. I think we have reason to be extremely satisfied with the whole of the working of this line as an electrical line. You have seen, no doubt, many paragraphs in the newspapers complaining of breakdowns on this line. We are, unfortunately, very much before the public at the present moment, and notice is taken of every little thing done on this line in a way that is never done in the case of other railways. We have run up to the present time about 11,000 trains over the line. The failures of our engines, which have been the chief cause of the delays out of those 11,000 trains, numbered only eighteen. I do not think you will say that that is a great figure, seeing that the number of trains run on our line is very large, and that it is quite impossible that so many should be run without some accident occasionally. That during the first six weeks of the existence of this new line there should have been only 18 failures is a fact creditable to the electrical system. Of course we are doing our best now to prevent, and, if possible, to get rid altogether of any ground for complaint, but whether we shall be able to do so or not with human inventions seems hardly likely to be the case; but we will do our best, so that the public will feel that they have little or no inconvenience from any accident. But, of course, we cannot do everything in six weeks. The result of those paragraphs in the newspapers is that many people who would naturally have travelled with us supposed that the line was stopped, and the traffic for the time being has been damaged; but I feel satisfied that we shall very soon be steadily improving the traffic on the line, and that you will in the end have a satisfactory result from it. The expenses of working it, so far as electricity is concerned, has turned out as far as we can see at the present moment satisfactorily. They are quite equal to what we anticipated from an economical point of view, and, on the whole, the prospects of the line are by no means gloomy. I do not know that I can say any more to you on the subject than that. You know what our object has been in introducing the Bill. If you think, on the whole, that it is desirable that we should run the risk of not proceeding with it we are quite in your hands with regard to the matter; but I think you would be wiser to let the Bill go on, and let us obtain powers, and deal with the undertaking afterwards in the way that we think most judicious. He concluded by moving a resolution approving of the Bill in question.

Mr. HUBBARD seconded the motion.

A SHAREHOLDER suggested that if the Bill were passed by Parliament it might be expedient not to proceed with the construction of the line until the Company had had more experience of its present line.

The CHAIRMAN pointed out that five years is the usual period given for the construction of a line, and if they desired not to go on with it the custom was to go to Parliament for an Abandonment Bill. If they desired to go on with it they could do so at any time within that period.

Mr. BROAD objected to any portion of the funds of the Company being devoted to that purpose.

The CHAIRMAN: We do not in the slightest degree want to proceed with the Bill if the shareholders do not like it. We have rather reluctantly ourselves gone into it as a protection to the shareholders. I have told you the circumstances, and if the shareholders think it is better to run the risk of withdrawing the Bill—for a very considerable risk is run in withdrawing it—it is for them to say so. We have done the best we

could in giving you an opportunity to discuss this question, and it is for you to decide. If you think it is better to withdraw it, we shall acquiesce.

A SHAREHOLDER asked who would have to pay for the Bill.

The CHAIRMAN replied that the shareholders of the existing line would if they were prepared to go on with it. The Bill was not likely to be seriously opposed or very expensive, probably £1,500.

Mr. H. BISHOP thought it would be much better to stick to the line they commenced with until it was proved and tested in every way. If other people took up the matter the shareholders in this Company could take shares in the other Company that might be formed. He did not think they should spend money on what was not contemplated in the first instance.

Mr. COURT said that he had not seen the plans of the proposed undertaking until that moment, and one would naturally like to have an opportunity of considering them before giving one's decision. Many of the shareholders were in the same position, knowing little or nothing of the proposal, and he thought that in the interests of all concerned it would be better to adjourn the meeting until such time as they thoroughly understood it. His own feeling was that if one or two small objections could be got rid of the scheme might be an advantage to the Company. But it was better to carefully discuss it.

The CHAIRMAN: You can adjourn until the 24th, the date of the general meeting.

Mr. W. A. SMITH asked what the amount of the capital was.

The CHAIRMAN replied that the amount of capital was apparently larger than what the present line cost. The present line cost £600,000, whereas it was proposed to raise £660,000 for the new one. In going through the City they must be aware that it might be necessary to pay a large sum for a particular site for a station. But the arrangements they made were such that they should practically get the money back, or get very good interest for it, which was the same thing, but they were obliged to have in their Bill powers for raising sufficient capital to cover the temporary costs they might incur. Otherwise the cost of the line would not be heavy, but very reasonable. There were very good reasons why the Bill had been drafted in its present form. He would, of course, like to go into them, but if the Bill was to be proceeded with, it would be desirable not to discuss those reasons publicly. But the Bill had been exceedingly well considered, and he would be glad to explain privately anything they might desire to know.

Mr. COURT formally moved that the meeting should be adjourned till the 24th inst., immediately after the conclusion of the business of the half-yearly meeting.

Mr. W. A. SMITH seconded the amendment, which

The CHAIRMAN put to the meeting and declared carried.

A SHAREHOLDER asked how many passengers had been carried by the existing line?

The CHAIRMAN: Up to the present moment we have carried somewhere about a million passengers.

Mr. COURT said he was very much pleased with the rapidity with which passengers were taken from one end of the line to the other.

The CHAIRMAN said that they must have patience with a new thing that had never been tried in the history of the world before. They had a great deal of anxiety in connection with it, and the staff were employed night and day. They had gradually to feel their way. All their difficulties and delays were capable of being remedied, and were being remedied, but they could not do everything in six weeks. They would be perfectly satisfied by-and-by. They were doing their very best, and no stone was being left unturned to make the undertaking a success.

Mr. W. A. SMITH proposed a vote of thanks to the Chairman, which brought the proceedings to a close.

## The Cuba Submarine Telegraph Company (Limited).

The following is the report of the Directors of the above Company for the half-year ending December 31, 1890, to be presented at the thirty-ninth ordinary general meeting of shareholders to be held at the office of the Company on the 11th inst. at 12 o clock:—

From the balance-sheet and accounts it will be seen that the gross receipts (including the balance brought from last account) amount to £21,325. 19s. 0d., and the gross expenditure (including the half of the annual payment on account of the 1881 cable) to £6,759. 11s. 3d., leaving a sum of £14,566. 7s. 9d. to the credit of revenue account. Of this the sum of £4,450. 13s. 10d. has been added to the reserve fund, which now stands at £79,000. The dividend on the Preference shares will absorb £3,000, and leave £7,115. 13s. 11d., out of which the Directors recommend the payment of a dividend on the ordinary shares at the rate of 8 per cent. per annum, free of income-tax, the balance, £715. 13s. 11d., being carried forward to the current half-year's account.

The new cable between Batabano and Cienfuegos, referred to in paragraph six of the last report, was completely laid on 19th instant, but will not be taken over from the contractors until it has undergone the tests required by the contract. The instalments already paid have been deducted from the reserve fund, which will also be charged with the balance of the contract price. The Cienfuegos-Santiago 1881 cable broke down on August 21st last, and the 1875 one, between the same points, became interrupted on 13th instant. The latter is now being repaired by the Company's engineer, the vessel which laid the new Batabano cable having been hired for the purpose, and the restoration of communication is daily expected. When this is accomplished the vessel will proceed to repair the 1881 cable, the cost of which has to be borne by Messrs. Hooper, the contractors.

A special meeting has been convened to remedy a defect in the Articles of Association which is deemed to be necessary in the interests of the shareholders.

With regard to the suit against the Spanish Government, the necessary forms for bringing the case under the consideration of the Contencioso Court are not yet complete, but it is expected that within a short time the case will be ready for hearing.

The usual comparative statement of traffic accompanies the Directors' report.

## CITY NOTES, &c.

**BRAZILIAN SUBMARINE TELEGRAPH COMPANY.**—The receipts of this Company for the week ended January 30th amounted to £6,215.

**CITY AND SOUTH LONDON RAILWAY COMPANY.**—The receipts of this Company for the week ended January 31st amounted to £704.

**DIRECT SPANISH TELEGRAPH COMPANY.**—The traffic receipts of this Company for the month of January were £2,147, against £2,415 last year.

**EASTERN TELEGRAPH COMPANY (LIMITED).**—The traffic receipts for the month of January, 1891, amounted to £60,005, and to £59,478 in the corresponding period of 1890.

**EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.**—The traffic receipts of this Company for the month of January, 1891, amounted to £46,575, and to £40,610 in the corresponding period of 1890. Increase £5,965.

**NEW COMPANIES REGISTERED IN JANUARY.**—Amongst the new companies registered at Somerset House during the month of January were the following:—

| | |
|---|---|
| Leeds Copper Company (Limited), £1 shares | £450,000 |
| North-Eastern Telephone Company (Limited), £1 shares | 4,600 |
| Shropshire Electric Light and Power Company (Limited), £10 shares | 25,000 |

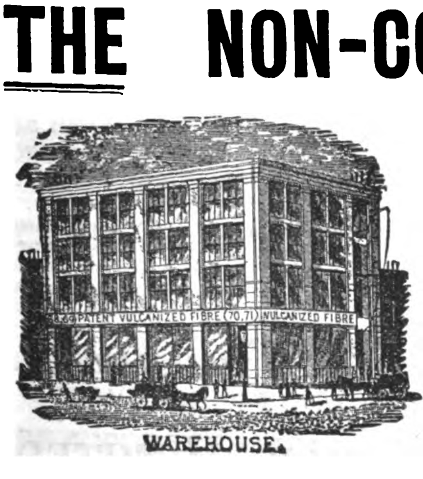
**VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY.**—The coupons on the debentures of this Company, now due, are payable on presentation at the Consolidated Bank (Limited), 52, Threadneedle-street.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY.**—The traffic receipts of this Company for the week ending January 30, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,996.

**WEST INDIA AND PANAMA TELEGRAPH COMPANY.**—The traffic receipts for the half-month ended Jan. 31st were £3,801, as compared with £3,556 for the corresponding period of 1890. The October receipts, estimated at £5,797, realized £5,847.

**WOODHOUSE AND RAWSON UNITED.**—The Directors of this Company have declared an interim dividend at the rate of 15 per cent. on the ordinary shares and 8 per cent. on the Preference shares, in respect of the profits to December 30th last.

# THE NON-CONDUCTOR OF ELECTRICITY.



WAREHOUSE.

**VULCANISED FIBRE,**
PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

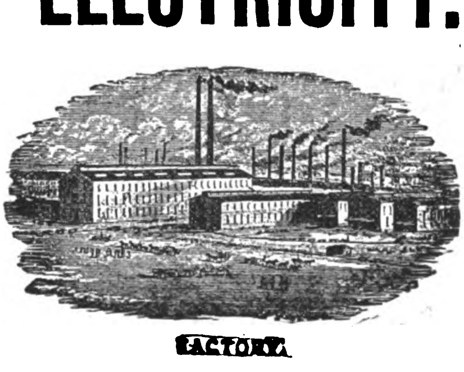
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

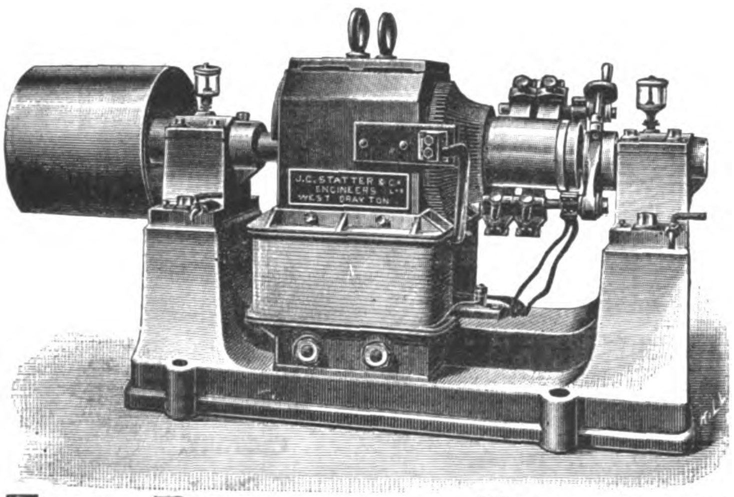
IMPROVEMENTS IN DYNAMOS.



STATTER-BRUNTON

DYNAMO.

**The latest design in the market, made with all the advantages of the latest scientific knowledge and the highest mechanical skill.**

The woodcut represents our B TYPE DYNAMO. A most efficient machine, working noiselessly, and without sparking or overheating; is highly finished and well proportioned. The output is so rated in our Catalogue that the machines may be worked very much in excess of their stated full output for short periods.

STOCK SIZES UP TO 77 KILOWATTS.

MACHINES BUILT TO 500 KILOWATTS.

THE ELECTRICAL ENGINEERING CORPORATION, LIMITED,
(STATTER'S) (UNITED.)

68, Victoria Street, London, S.W. WORKS:—ALLIANCE ENGINEERING WORKS, WEST DRAYTON, NEAR LONDON.

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 665.—Vol. XXVI. FRIDAY, FEBRUARY 13, 1891. Price Fourpence.

## NOTES.

The proceedings of the Electrical Standards Committee appointed to advise the Board of Trade, have been kept profoundly secret, but the public are now permitted to have a glimpse at some of the work in hand by the publication of the draft resolutions, which will be found in another column. These resolutions will be submitted to the Committee next Friday, and the fact of their being published may be taken as a sure indication that the members of the Committee are unanimous, except, perhaps, as to the exact value of a Clark cell in volts. The resolutions contain several concessions and compromises which, if they fail to please everybody, must be acknowledged to represent a praiseworthy attempt to execute this difficult task. That the C.G.S. system should be adopted for determining the dimensions was to be expected, and it will be hailed by many persons as a step towards the general use of the metric system. The grounds for such a hope are, however, slender in the present case; for, with the exception of Mr. Sprague's carefully worked out scheme of chemics and equivolts, which referred to grains and feet though not independent of the received units, no one has attempted to construct a system of electrical measurements with the British standards of length and mass.

The adoption of a "mercury ohm" is a concession to our Continental friends, who would never recognise any other mode of definition. But the construction of a material standard of solid metal is a compromise on which the committee is to be congratulated, as practical engineers will have nothing to do with columns of mercury. The seventh resolution seems to have been suggested by the Standards Department of the Board of Trade, for it resembles the provisions made for the replacing of the standard yard should it again be destroyed. It was proposed that it should be replaced by reference to pendulum experiments, but whether from any want of confidence in the state of knowledge, or on account of some departmental principle, it was enacted, as in the present resolution, that copies should be constructed, and that they, rather than fresh absolute determinations, should be used if occasion should arise. In the case of the ohm, however, periodic comparisons must be made, as changes certainly do occur, and as these changes did not appear, at the last British Association meeting, to be thoroughly understood, there is room for argument that the standard, if destroyed, should be redetermined.

If the "mercury ohm" be a mark of respect to the Continent, the "silver ampere" is a tribute to Cambridge, and "the instrument constructed on the principle of a balance" is a compliment to Glasgow; while the C.G.S. system and science generally are thrown to the winds in the final recommendation, eminently practical and thoroughly reliable though it be, of offering the Clark cell as a standard of electrical pressure.

The more we examine the prospectus of "The City of London Electric Lighting (Pioneer) Company (Limited)," the more difficult do we find it to discover its *raison d'être*. The Brush Company and the Laing, Wharton, and Down Company has each an excellent business of its own, and such an undertaking as the lighting of the City might well be transferred to a company formed specially for that purpose. They have made contracts with the Commissioners which "require that the works. . . . shall be commenced by February 19 and February 28, 1891, respectively. It is to comply with this requirement that this Pioneer Company has been formed, the short time at disposal being insufficient to enable the arrangements for the formation of the larger company to be completed." The Royal Assent was given to the Provisional Orders in August for two-thirds of the work, and it has taken more than seven months to make this preliminary step. The contracting companies are debarred from subletting their concessions to any existing metropolitan supply companies; but this pioneer Company, formed under the auspices of the Electric and General Investment Company, which itself is formed to supply ready money to contractors "for the purpose of facilitating the promotion and development of undertakings for electric lighting," &c., is, after all, only formed "with the intention of forming a larger company" which is ultimately to do the work. Neither the pioneer company nor its prospective offspring has any *locus standi*, and are not recognised by any of the several authorities concerned. The Board is eminently fitted for some of the objects of the concern, but pioneering the supply of electricity for public and private purposes is not one of them. Among this multitude of companies there is more scope for the art of the promoter than for the talents of the engineer.

The most ardent advocates of the electro-magnetic theory will be willing to admit that it is not an easy one to trace out correctly in its different aspects; and the discussion on this subject which is at present being carried on in our correspondence columns will serve a useful purpose if it removes some of the vagueness attaching to ordinary notions about the theory,

Digitized by Google

or if it crystallises into more definite form the objections of its opponents. Mr. Sprague calls out for proofs of the existence and properties of the ether, but he makes demands upon Maxwell's theory for many more hypotheses with regard to the medium than are really needed. Careful reading of the different letters which have been written will show that much of the present controversy arises simply from a different use of terms, and it is thus fortunate that Prof. Thompson, in this week's letter, renders the real point at issue clear by distinctly stating his views in tabular form.

Mr. Sprague's contention that we know nothing about the ether will not be seriously objected to, since he admits the power of the ether to transmit light across space by undulatory motion. Maxwell made no hypothesis as to the nature of the ether, and, although many theories have been put forward, Sir William Thomson, to whom the ablest of these are due, confessed, in his Presidential Address in 1889, that after over forty years' consideration of the subject he still must reserve *for a future paper* any explanation of the nature of the etherial mechanism. The experiments of Hertz have not solved the mystery of the ether, but they have shown that electric and magnetic actions take time to travel from the origin of the disturbance. As Mr. Sprague states, undulatory disturbances must produce undulatory actions at a distance, but it does not follow that they will be perfectly "in step" unless the disturbances travel with an infinite velocity. If the velocity is finite, the more distant effects will lag behind the nearer ones, and by considering this lag it has been shown that electric actions are propagated with the speed of light. The medium which transmits such effects must have exactly the same properties as that which transmits light, and, without further assumption, may be regarded as the same.

Mr. Sprague takes uncertain ground when he boldly champions the notion that electric energy is conveyed longitudinally in the direction of the current instead of transversely. It would be impossible experimentally to prove either theory, because the movements of energy cannot at present be traced; but a careful comparison of the two shows that, whereas the latter theory has a scientific basis, the former has nothing but long custom to recommend it. One was arrived at by mathematical reasoning, while the other is a mere arbitrary hypothesis. What kind of proof can Mr. Sprague give of the longitudinal theory which he upholds?

A novel distinction between paramagnetic and diamagnetic bodies has been pointed out by M. P. Joubin in the current number of the *Comptes Rendus*. For those metals which obey Dulong and Petit's law of atomic heat, it is possible to calculate quantities which are proportional to the number of molecules contained in a unit volume, and hence the average distance of the molecules from each other can be compared. When these distances are examined in connection with the corresponding values for the specific resistance, it is found that the metals arrange themselves into two groups, those in one class being paramagnetic, while the remainder are diamagnetic. The two curves which represent the results graphically are found to be such that the number of molecules per unit volume is proportional to the sixth root of the specific resistance for magnetic bodies, and inversely proportional to that quantity for diamagnetic ones. A comparison of the thermo-electric powers of the metals, with the corresponding molecular numbers, yields a similar result, the metals dividing into exactly the same groups, although the shape of the curves is somewhat different, and it is significant that a comparison of the magnetic coefficients, as far as our present knowledge of these quantities renders it possible, leads to the same grouping. While it would no doubt be rash to enter too fully into Prof. Crookes' ideas about the genesis of the elements, it will be admitted that investigations of this nature are not only serviceable in connecting a number of isolated phenomena, but also tend to show the direct dependence of the physical properties of metals on their molecular structure in general, and in particular on the average distance of their molecules from each other.

Our New York correspondent calls attention this week to a result, not altogether satisfactory, which has followed from the extension of electric traction in Boston. While the extreme outlying suburbs of that city have greatly benefited by the increased rapid transit facilities afforded by the electric car, the more central districts are being deserted. Much the same phenomenon, due to much the same cause, has been long taking place in London. The suburban lines are constantly pushing further and further out into the country, with the result that the metropolis grows by accretion rather than by intussuception, to use biological expressions. It will be interesting to see whether the Bostonian property holders will adopt a more effective policy than that of opposition to electric traction, and take the heroic course followed in many instances in London of rebuilding the districts to suit the exigencies of the new situation.

**The "Sirene."**—The construction of a new electrical submarine torpedo boat, the "Sirène," is being actively pushed forward at Toulon.

**A Long Run.**—During the December fogs one of the dynamos of the House-to-House Station is stated to have run uninterruptedly for nearly four weeks (665¾ hours).

**New Peru and Chili Cables.**—The "Silvertown" has been reported from Arica, all well. She completed the cables between Chorillos—Yquique—Valparaiso on February 2nd.

**Berlin Electric Lighting Statistics.**—According to the *Zeitschrift für Elektrotechnik* the present number of 8 candle-power glow lamps installed in Berlin is 100,000, and that of arc lights 3,000.

**Portsmouth.**—The Electric Lighting Committee have decided to recommend the Town Council to take the management of the electric lighting into its own hands instead of leasing the powers obtained to a private company. The low tension system is recommended.

**A Helmholtz Medal.**—An International Committee has been formed to collect the sum necessary for a marble bust to Prof. Helmholtz, and for a Helmholtz medal, to be bestowed on the most eminent German and foreign physicists, in memory of the Professor's seventieth birthday, on August 31st.

**Chelmsford.**—The irregular working of the electric light has led to a complaint being made to Messrs. Crompton by the Town Council, and the sub-committee has been instructed to

Digitized by Google

endeavour to ascertain from Messrs. Crompton the advisability of lighting the town by incandescent lamps of equal power to, and in lieu of, the present arc lamps.

**Aberdeen.**—A sub-committee of the Corporation Gas Committee has instructed the Gas Manager to report on the cost of laying down electric lighting plant within the area sanctioned by the Provisional Order obtained last year, and also to procure from three of the best electrical engineers in London estimates of the cost at which they would be willing to supply the light.

**"Electric Light Installations and the Management of Accumulators."**—It has been pointed out to us, in connection with our review of this work, which appeared on page 426 of our last issue, that the chemical symbols expressing the reaction that takes place in an accumulator during charging, referred to by our reviewers, were not cast in the form of an equation, and that the context shows that they were merely intended to explain in a briefer way than words could do the author's idea of what goes on.

**The Registration of Trade Marks in Japan.**—The British and Foreign Patents and Trade Marks Society have called the attention of the Foreign Office to the fact that the excellent regulations in force in Japan since July 1, 1889, cannot be made use of by British subjects for the protection of their interests. In reply the Foreign Office state that the hardship involved by this law will not be lost sight of in future negotiations for treaty revision.

**A "Lost Child" Telephone Service.**—In Indianapolis as soon as a child is lost the information is telephoned to the central station. When a lost child is found this also is telephoned. The finding is then telephoned to the number that reported the losing. In some cases the child has been restored in twenty minutes after the loss was reported. The service costs the telephone company comparatively nothing, and no charge for finding lost children is made to parents or friends. This service has made many friends for the telephone company.

**Electric Traction in Boston.**—The West End Street Railway Company have awarded the contract for the large generators for the new power house to the Thomson-Houston Electric Company. The order at present is for 17 of these generators, but 34 will be required in all. Each generator is to be capable of giving out 360,000 watts, at a maximum pressure of 600 volts, that is to say, the total available E.H.P. will amount to over 8,000. The generators will be of the multipolar type, with Gramme armatures, compound-wound, and about 31 tons in weight.

**Personal.**—Mr. R. T. Glazebrook, of Trinity College, has been appointed assistant-director of the Cavendish Laboratory.——Prof. J. A. Ewing, Professor of Mechanism at Cambridge, has been made Master of Arts, *honoris causâ*.——Mr. H. E. Hunt has been appointed managing electrical engineer to the Taunton Electric Light Company from February 1st, in the place of Mr. O. V. Thomas. Mr. Hunt was formerly in the employ of the Taunton Company for a period of three years, and left about twelve months since to fill an important position at the Bath Electric Light Works.

**A Novel Use for the Electric Heater.**—The Burton electric heater has recently been put to a novel use in the Government bureau of printing and engraving in Washington, D.C. The plates from which bank notes are printed have first to be warmed, when the ink is rubbed into the cuts after the manner of printing visiting cards. The ink is then cleaned off the face of the plate while hot and the impression taken. Hitherto gas stoves have been used for the purpose of warming these plates, but objections to these are many and obvious, and electric heaters have been fitted instead.

**The High-pressure Transmission of Power Experiments at the Oerlikon Works.**—The experiments with high-pressure currents, referred to on page 386 of our issue of January 30, consisted in the transformation of a 100 volt current by means of the Oerlikon Company's "oil transformer" to a pressure of 33,000 volts. The current at the latter pressure traversed a conductor 7km. in length, and was then converted back to 100 volts, and used to run glow lamps. The result is stated to be that the practicability of transmitting power from Lauffen to the Frankfort Exhibition has been demonstrated.

**Vulcanite.**—The mean of twelve determinations of the coefficient of linear expansion of vulcanite, by Mr. A. M. Mayer—*American Journal of Science*—obtained by means of a specially devised piece of apparatus, gave the value 0·0000636, between the temperature at which the experiments were made, viz., 0deg. and 18deg. C. The cubical expansion of the substance is closely represented by the formula $v_t = v_0 + 0{\cdot}000182\,t + 0{\cdot}00000025t^2$. The specific heat equals 0·33125. The angle of maximum polarisation of a polished surface of vulcanite was found to be 57° 29′. Hence the index of refraction equals 1·568.

**Newcastle.**—At a recent meeting the Town Council considered the application of the Newcastle and District Electric Lighting Company for a Provisional Order. It was ultimately resolved to give consent to the application upon the lines recommended by the Town Improvement Committee, which are that the Corporation should have the option of purchase at the end of 31 years, that the maximum rate of dividend should be 8 per cent., cumulative, and all profits above such dividend should be equally divided between the consumers and the shareholders. These terms have been agreed to by the Company.

**The Measurement of Large Currents.**—For the accurate measurement of large currents, such as are obtained from accumulators (a point on which technical literature does not afford much information), F. Himstedt makes use of a tangent galvanometer, with two consecutive copper rings, each 1cm. broad and ·4cm thick, of radii 23·276 and 27·422 cm. respectively. These rings are connected in opposition, so that the needle is acted upon by a differential couple. The advantages of this method are that the measuring apparatus is inserted in the actual circuit, that only a single observation is required, and that no resistance measurements are necessary.

**Bath.**—At a recent meeting of the Surveying Committee, a deputation appeared before the Committee on behalf of the residents in the middle of Gay-street, asking that some improved mode of distributing the electric light at present given should be adopted. Under the present state of things their doorways were in complete darkness. Mr. Sturges said this matter had been under the consideration of the Lighting Committee, but until the report of Prof. Forbes had been received upon the installation they had not thought it well to make any alterations. They would, however, deal with the matter as early as they possibly could.

**The Patent Office.**—Mr. Leng asked the Chancellor of the Exchequer on Monday evening whether he would consider the propriety of applying the surplus of £93,534, received by the Patent Office in excess of its expenditure, to a large reduction of the present heavy renewal fees. In reply, the Chancellor of the Exchequer stated that there was much to be said in favour of the present scale; it operated in the later years to cause useless and unsuccessful patents to fall out. Some people believed that this was an advantage, and not a disadvantage, to British trade. Sanction had been given to a large expenditure for building a new Patent Office, and providing additional facilities to the public.

**The South Kensington Subway Bill.**—On the motion for the second reading of the South Kensington and Paddington Subway Bill in the House of Commons yesterday Mr. Baumann protested against the conduct of the promoters of the Bill, who, he said, would not adjourn the second reading in order to give him an opportunity of ascertaining the feelings of the 60 metropolitan members on the subject. The beauty of Kensington Gardens was imperilled because a tunnel was to be made under, and a station erected in the middle of the gardens, simply to put money in the tills at the Albert Hall. Obviously, this was a question which should not be settled in haste. Mr. Whitmore supported the second reading, and remarked that in no way would the gardens be interfered with. Mr. Courtney thought it right to say that the promoters had done nothing unusual. The second reading was then agreed to.

**The Science Collections at South Kensington.** — In the House of Commons on Friday last Sir H. Roscoe asked the First Commissioner of Works what steps had been taken to carry out the undertaking given by him on April 1, 1890, with regard to the housing of the science collections at South Kensington. Mr. Plunket stated in reply that it had been decided to proceed at once with the completion of the buildings on the east side of the Exhibition-road. These would ultimately be devoted wholly to art collections, although for some years it was probable that some portions of them might be temporarily available for science collections. He was now in communication with the Science and Art Department as to the best means of providing for scientific requirements, and he hoped soon to submit a proposal to the Treasury. The buildings on the east side of Exhibition-road would cost some £300,000 or £400,000.

**City and South London Railway.**—Last week a stoppage occurred on the City and South London Railway which, says the *Engineer*, was the cause of considerable annoyance as it was at a rather busy part of the day. Those connected with the line had, however, the most cause for feeling the annoyance, the cause of the stoppage being of such a very simple and easily remediable kind. There is a lock-nut on the armature spindle of the motors, between the armature and the brass bearing at one end. This nut, like a good many other lock-nuts, unlocked itself, and turned back until it touched the brass bearing. When this occurred the direction of rotation of the armature spindle soon caused the nut to lock hard against the brass, and ultimately to fix the spindle absolutely. The cause was not ascertained until the engine had been hauled away, with the drivers fixed, by another engine. It might have been put right in five minutes, if the real cause had been guessed, but it was too simple a cause to be guessed very readily. It was simply a bit of electro mechanics without the least bit of mystery.

**The Electrical Bills of the Session.**—On Saturday the report of the Board of Trade upon the railway, canal, tramway, gas, electric lighting, and water Bills of the Session 1890-91 was issued. It shows that the total number of Bills relating to such undertakings deposited during the Session number 148, against 173 in the Session of 1890; the total amount of money proposed to be raised is £58,132,590, against £40,106,611, an increase of £18,025,979. Thirteen Bills relate to tramways, and propose the construction of 24 miles of tramway, and the raising sums of money amounting in the aggregate to £500,000. As compared with 1890, the number of Bills shows a decrease of six, and the capital proposed a decrease of £153,250. Of the 38 gas, electric lighting, and water Bills one only relates to gas and electric lighting. The number of applications made to the Board of Trade for Provisional Orders relating to tramways and the supply of gas and water and electric lighting amounts to 91. Of the 14 relating to gas and water, the proposed capital is £259,250, of the seven tramways £120,632, and of the 70 electric lighting orders £2,125,000.

**The Curtis Conduit System.**—The growing dislike in the States to the overhead system of traction, and the continued opposition of the telephone companies to earth returns, have resulted in the bringing out of numerous complete metallic circuit conduit systems, the majority of which have so far been remarkable neither for novelty nor practicality. One of the latest systems is that due to a Mr. H. N. Curtis, of New York. The conduit in this case is built up of sheet iron. The slots are closed by iron angle bars, upon which are fastened rubber strips, which almost entirely cover the top of the metal bar, leaving a small portion only uncovered for the purpose of making metallic contact with the trolley wheel, and which effectually seal the conduit, and prevent the entrance of water and dirt. These bars are made in lengths of three or four feet, and joined together flexibly so that they form a continuous length which can be depressed. As the car travels along, the trolley wheels depress the bars and bring them in contact with the conductors in the slot; as soon as the pressure of the trolley wheel is removed, the flexible contact strip returns to its normal position by the pressure of springs. A rotary brush attached to the car in advance of the trolley wheel clears the contact strip of all foreign material.

**The Henry Electric Motor Truck.**—The *Electrical World*, in a recent issue, describes a new style of motor and tram-car truck designed by Mr. J. C. Henry. In this motor and truck all spring supports are avoided. Only one motor is employed, and only one pair of wheels is driven by the gearing, the other being operated by a connecting rod. The motor, which has a Gramme ring armature, is rigidly fastened to the steel frame that connects the axles, its ends having bearings on 3in. steel axes, parallel with the axles of the wheels. The gearing consists in the well-known epicyclic arrangement, capable of running freely when the epicyclic pinion is free to move, and exerting its full power when the pinion is held fast as it can be by the clutch lever. The armature therefore can run all the time, or be allowed to give its full speed before any of the load is thrown on; as soon as the clutch is tightened the clutch can take hold and utilise its momentum in starting the car, thereby avoiding a sudden rush of current. The epicyclic gear is enclosed in a dust-tight case and runs in oil, so that the noise is diminished. The armature is only geared down once, the reduction being seven to one. A slight modification will allow the armature to be connected directly with the internal gear after the car is under way, thus allowing very high speeds. The motor, which is of 30 horse-power weighs a little over one ton.

**Elihu Thomson Lightning Arrester.**—Where a number of breaks are made in a circuit or a number of discharge spaces have to be successively traversed by a discharge, the total distance represented by the sum of the breaks, can be made much greater than the striking distance of the discharge between two plates where a single break only exists. Advantage has been taken of this by Prof. Elihu Thomson in the construction of a lightning arrester. This device consists of a pile of circular metallic plates separated by insulating washers, each washer projecting a little beyond the metallic plates. Each metallic disc is provided with a narrow projecting strip which carries a discharge terminal, such as a ball, which lies within a small distance of the succeeding ball of the series. At one end of the series is a connection to the line, and at the other a connection to the earth. The effect of arranging the plates in this way is to give each one a certain static capacity and permit the discharge points to be adjusted at any desired distance apart by simply swinging the plates around circularly so as to arrange the discharging points in a spiral fashion around the column of plates. The sum total of the spaces that must be jumped by the discharge is largely in excess of the striking distance of an ordinary lightning arrester, or several times the largest possible space which could be used with safety to protect a dynamo against injury from discharges.

**Obituary.**—The death of Mr. Robert Forester Mushet, the well-known metallurgist, took place on the 3rd inst. Mr. Mushet devoted the greater part of his life to the improvement of the manufacture of crucible steel at his small experimental works at Coleford, in the Forest of Dean. Among the many notable developments originated there was the production of specially hard steel by the addition of tungsten and other metallic elements to the iron in the crucible, which resulted in the production of the well-known "special tool steel," which has proved of immense value in the engineer's workshop. These results, were, however, overshadowed by his application of spiegeleisen to the Bessemer process. It is sad to think, says the *Engineer*, that the discoverer lost the fruits of his labour through the trustees of his patent omitting to pay the fees due in the third year. The value of the discovery was, however, fittingly acknowledged by the award of the Bessemer Gold Medal of the Iron and Steel Institute in 1876, and in a more substantial manner by Sir Henry Bessemer.——We regret to announce the death at Madrid, on the 2nd instant, of Senor Angel Mansi, who was until recently Director-General of the Spanish Posts and Telegraphs, and represented Spain as Chief Delegate at the Paris Telegraph Conference, where his amiable and courteous manner was much appreciated by all the Delegates.

**International Niagara Commission.**—The Cataract Construction Company, having invited various firms to send in projects for the utilisation of about 125,000 horse-power at Niagara, and its distribution, partly to an industrial district in the neighbourhood of the Falls, and partly to the town

Digitized by Google

of Buffalo, appointed an International Commission to adjudicate on the plans sent in. This Commission consisted of Sir William Thomson, F.R.S., President; Dr. Coleman Sellers, Prof. E. Mascart, and Colonel Th. Turrettini. After a careful examination of a large number of projects sent in, in accordance with the letter of invitation of the Cataract Company, the Commission have awarded the following prizes:— Projects combining the Development of Power and its Distribution: 1st prize not awarded; 2nd prize, MM. Faesch and Piccard (Geneva) and MM. Cuenod, Sautter and Co. (Geneva); 3rd prizes (four), M. A. Hillairet and M. Bouvier (Paris), M. Victor Popp and Prof. Riedler (Berlin), Prof. L. Vigreux and M. L. Levy, the Pelton Water Wheel Company, San Francisco, California, and Norwalk Iron Works Company, S. Norwalk, Connecticut. Projects for the Hydraulic Development of the Power: 1st prize, MM. Escher Wyss and Co. (Zurich); 2nd prizes (two), Ganz and Co. (Budapest), Prof. A. Lupton (Leeds) and Mr. J. Sturgeon. Projects for the Distribution of the Power: No prize awarded.

**The Use of Electric Motors in War Ships.**—Although England may claim to rank foremost in the application of the electric light to her war-ships, and the fittings for firing guns by electricity have been in use for many years, it would appear, says the *United Service Gazette*, that we are, for the present at any rate, rather behind some foreign Powers in the utilisation of the electric current as a motive power. Whilst our prominent naval architects have been thinking about it the French Admiralty have, in one of their new ironclads, abandoned hydraulic power in favour of electricity for moving the turrets, working the guns and ammunition hoists. The same idea has been approved by the Chilian Government, and applied to three of their large war-ships. The Americans are also using electric motors in some of their new ships for training the guns; and it may be interesting to note here that the "Baltimore" is probably the first war-vessel in which a telephone service has been established so as to enable the commander to communicate from the conning tower with the various parts of the ship. A still wider field of action is open to the use of electrical energy in substitution for the large number of auxiliary engines, both steam and hydraulic, now existing on board a large man-of-war. They are to be found scattered all over the ship, involving a labyrinth of steam, exhaust, circulating, and drain pipes, complex in arrangement, and requiring constant care and attention to keep in order. Joints and valves leak, steam condenses, and water freezes, as in the "Camperdown" lately, totally disabling some part of the mechanism. Repairs with only the ship's resources are difficult. The complicated system of steam circulation would also be extremely dangerous to the crew when the vessel was in action. It has been truly said that "almost fabulous expense is one of the characteristics of modern warfare." But we do not think, if the experiment were tried of extending the electric plant now fitted to our men-of-war by substituting electric motors for the present hydraulic and steam auxiliary engines, that there would be any grounds to find fault either with their safety, utility, or economy.

**Ferranti Alternators.**—The following list of some of the supply stations equipped with Ferranti plant may be of interest. Deptford Station: the capacity of the plant now erected at Deptford is 90,000 lamps, and this capacity is being increased by the building of two 200,000 light machines. Rochester: small station capacity of 3,000 lamps. Glasgow: two alternators, capacity of 6,000 lamps. La Plata: three alternators, capacity of 9,000 lamps. Rosario: two alternators, capacity of 6,000 lamps. Barcelona: two alternators, capacity of 6,000 lamps. Municipal Station, Paris: three alternators, capacity of 9,000 lamps. Plaza de Toros, Paris: one alternator, capacity of 3,000 lamps. Nancy: three alternators, capacity of 9,000 lamps. Havre: two alternators, capacity of 12,000 lamps. Melun: two alternators, capacity of 6,000 lamps. Troyes: two alternators, capacity of 6,000 lamps. Nimes: two alternators, capacity of 6,000 lamps. Dijon: one alternator, capacity of 3,000 lamps. Sens: one alternator, capacity of 3,000 lamps. St. Ceré: one alternator, capacity of 600 lamps.

**Dublin.**—Our Dublin correspondent informs us that the Corporation have accepted the tenders of the Electrical Engineering Company of Ireland and of the Irish House-to-House Electricity Company. The facts of the case are, we believe, somewhat as follows:—The Irish House-to-House Electricity Company tendered upon the specification published by the Dublin Corporation and submitted their own plans, which have not been altered in one single detail. The Electric Lighting Committee of the Corporation, however, reported to that body that on the whole they considered the contract should be given to the Electrical Engineering Company of Ireland, but there was a strong minority in favour of the contract being given to the Irish House-to-House Company, in order to secure a station upon the lines of that at West Brompton. With a view of meeting both parties in the Corporation, the two companies, viz., the Electrical Engineering Company of Ireland, and the Irish House-to-House Company, settled terms of amalgamation, and the Committee of the whole house of the Dublin Corporation on Wednesday afternoon decided to give the contract to the Electrical Engineering Company of Ireland on the assurance that they would have the assistance of the Irish House-to-House Company in carrying the contract out. This resolution was confirmed by the whole of the Council at a subsequent sitting on Wednesday evening. The resolution was to the effect that the Committee were empowered to close the contract with the Electrical Engineering Company of Ireland, with such modifications as they might deem fit, and it appears probable that the incandescent lighting portion of the contract will be carried out in accordance with the plans submitted by the Irish House-to-House Company, and the arc lighting plant in accordance with the plans submitted by the Electrical Engineering Company of Ireland.

**The Action of the Silent Discharge on Chlorine.**—Arguing from the fact that oxygen gas, when subjected to the silent discharge, partially undergoes condensation into ozone, it seemed possible, says Mr. H. M. Vernon, in the *Chemical News*, that other elementary gases, as chlorine and bromine vapour, might undergo an analogous change when subjected to the same treatment. A glass tube, with a U-shaped index of fine-bore glass tubing, was filled with purified and dried chlorine. After passing a current of the gas through the tube for some time, the end was sealed in the blowpipe flame. The tube was then warmed slightly, and a few bubbles of gas thus driven out. The end of the index tube dipped under strong sulphuric acid saturated with chlorine gas, so that, on cooling, a short column of the acid was drawn up. This served as an index for any changes of volume which might take place in the chlorine in the tube. A silent discharge of electricity was then passed. The volume of the gas was observed to increase slightly, but afterwards it remained quite constant even after the discharge had been passed for several hours. We may therefore conclude that no allotropic change takes place when chlorine gas is subjected to the silent discharge of electricity, the initial increase of volume being merely due to the heating effect the discharge has upon the gas. Into another similar tube, filled with chlorine, was introduced a small quantity of liquid bromine. The tube thus contained chlorine saturated with bromine vapour. The silent discharge on being passed through this tube did not produce any different effect than for chlorine alone, so we may conclude that bromine vapour also does not undergo any allotropic condensation when subjected to the influence of a silent discharge of electricity. The fact that oxygen gas is capable of undergoing condensation while chlorine and bromine are not is easily explained. The oxygen atom, being divalent, is capable of uniting itself to two other atoms of oxygen or other elements, and thus with oxygen forming ozone. The atoms of chlorine and bromine, however, being only mono valent, have all their affinity satisfied when they are united to a single other atom of chlorine and bromine. It is not possible, therefore, that condensation can take place if the atoms remain monovalent. Hydrogen gas and iodine vapour are in a similar manner debarred from undergoing condensation. Mr. Vernon, therefore, comes to the conclusion that it is most improbable that any other element but oxygen will be found capable of undergoing molecular condensation when in the gaseous state and subjected to the silent discharge.

## ELECTROMAGNETIC THEORY.—IV.

BY OLIVER HEAVISIDE.

*(Continued from page 389.)*

§ 20. Our primary knowledge of electricity, in its quantitative aspect, is founded upon the observation of the mechanical forces experienced by an electrically charged body, by a magnetised body, and by a body supporting electric current. In the study of these mechanical forces we are led to the more abstract ideas of electric force and magnetic force, apart from electrification, or magnetisation, or electric current, to work upon and produce visible effects. The conception of fields of force naturally follows, with the mapping out of space by means of lines or tubes of force definitely distributed. A further and very important step is the recognition that the two vectors, electric force and magnetic force, represent, or are capable of measuring, the actual physical state of the medium concerned, from the electromagnetic point of view, when taken in conjunction with other quantities experimentally recognisable as properties of matter, showing that different substances are affected to different extents by the same intensity of electric or magnetic force. Electric force is then to be conceived as producing or being invariably associated with a flux, the electric displacement; and similarly magnetic force as producing a second flux, the magnetic induction.

If **E** be the electric force at any point and **D** the displacement, we have

$$\mathbf{D}=c\mathbf{E} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

and similarly, if **H** be the magnetic force and **B** the induction, then

$$\mathbf{B}=\mu\mathbf{H} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Here the ratios $c$ and $\mu$ represent physical properties of the medium. The one ($\mu$), which indicates capacity for supporting magnetic induction, is its inductivity; whilst the other, indicating the capacity for permitting electric displacement, is its permittivity (or permittancy). Otherwise, we may write

$$\mathbf{E}=c^{-1}\mathbf{D} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

$$\mathbf{H}=\mu^{-1}\mathbf{B} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

and now the ratio $c^{-1}$ is the elastivity and $\mu^{-1}$ the reluctivity (or reluctancy). Sometimes one way is preferable, sometimes the other.

§ 21. Al space must be conceived to be filled with a medium which can support displacement and induction. In the former aspect only it is a dielectric It is, however, equally necessary to consider the magnetic side of the matter, and we may, without coining a new word, generally understand by a dielectric a medium which supports both the fluxes mentioned.

Away from matter (in the ordinary sense) the medium concerned is the ether, and $\mu$ and $c$ are absolute constants. The presence of matter, to a first approximation, merely alters the value of these constants. The permittivity is always increased, so far as is known. On the other hand, the inductivity may be either increased or reduced, there being a very small increase or decrease in most substances, but a very large increase in a few, the so-called magnetic metals. The range within which the proportionality of flux to force obtains is then a limited one, which, however, contains some important practical applications.

When the fluxes vary, their rates of increase $\dot{\mathbf{B}}$ and $\dot{\mathbf{D}}$ are the velocities corresponding to the forces **E** and **H**, provided no other effects are produced. The activity of **E** is $\mathbf{E}\dot{\mathbf{D}}$, and that of **H** is $\mathbf{H}\dot{\mathbf{B}}$. The work spent in producing the fluxes (not counting what may be done simultaneously in other ways) is, therefore—

$$\mathrm{U} = \int_0^{\mathrm{D}} \mathbf{E}\, d\mathrm{D}, \qquad \mathrm{T} = \int_0^{\mathrm{B}} \mathrm{H}\, d\mathrm{B}, \quad . \quad . \quad . \quad (5)$$

where U is the electric and T the magnetic energy per unit volume.

When $\mu$ and $c$ are constants, these give

$$\mathrm{U} = \tfrac{1}{2}\mathrm{ED} = \tfrac{1}{2}c\mathrm{E}^2 \quad . \quad . \quad . \quad . \quad . \quad (6)$$

$$\mathrm{T} = \tfrac{1}{2}\mathrm{HB} = \tfrac{1}{2}\mu\mathrm{H}^2 \quad . \quad . \quad . \quad . \quad . \quad (7)$$

to express the energy stored in the medium, electric and magnetic respectively.

When $\mu$ and $c$ are not constants, the previous expressions (5) will give definite values to the energy provided there be a definite relation between a force and a flux. If, however, there be no definite relation (which means that other circumstances than the value of the force control the value of the flux), the energy stored will not be strictly expressible in terms simply of the force and the flux, and there will be usually a waste of energy in a cyclical process, as in the case of iron, so closely studied by Ewing. This does not come within the scope of a precise mathematical theory, which must of necessity be a sort of skeleton framework, with which complex details have to be separately adjusted in the most feasible manner that presents itself.

§ 22. But a precise theory nevertheless admits of considerable extension from the above with $\mu$ and $c$ regarded as scalar constants. All bodies are strained more or less, and are thereby usually made eolotropic, even if they be not naturally eolotropic. The force and the flux are not then usually concurrent, or identical in direction. But at any point in an eolotropic substance there are always (if force and flux be proportional) three mutually perpendicular axes of concurrence—the principal axes—when we have (referring to displacement)

$$\mathrm{D}_1=c_1\mathrm{E}_1, \qquad \mathrm{D}_2=c_2\mathrm{E}_2, \qquad \mathrm{D}_3=c_3\mathrm{E}_3,$$

if the $c$'s are the principal permittivities, the E's the corresponding effective components of the electric force, and the D's those of the displacement. If **E** be parallel to a principal axis, so is **D**. In general, by compounding the force components, we obtain **E** the actual force, and by compounding the flux components obtain **D** the displacement to correspond, which can only concur with **E** in the above-mentioned special cases if the principal permittivities be all different. But should a pair be equal, then **E** and **D** concur in the plane containing the equal permittivities, for the permittivity is the same for any axis in this plane.

The energy stored is still half the scalar product of the force and the flux, or $\tfrac{1}{2}\mathrm{ED}$, understanding that the scalar product of two vectors, which is the product of their tensors (or magnitudes) when they concur, is the same multiplied by the cosine of their included angle in the general case.

Vector analysis is, I think, most profitably studied in the concrete application to physical questions, for which, indeed, it is specially adapted. Nevertheless, it will be convenient, a little later, to give a short account of the very elements of the subject, in order not to have to too frequently interrupt our electromagnetic arguments by mathematical explanations. In the meantime, consider the dielectric medium further.

§ 23. The two quantities $c$ and $\mu$ are to be regarded as known data, given over all space, usually absolute constants; but when the simpler properties of the ether are complicated by the presence of matter, then varying in value from place to place in isotropic but heterogenous substances; or, in case of eolotropy, the three principal values must be given, as well as the direction of their axes, for every point considered. Keeping to the case of isotropy, the *ratios* $c/c_0$ and $\mu/\mu_0$ of the permittivity and inductivity of a body to that of the standard ether are the specific inductive capacities, electric and magnetic respectively: and are mere numerics, of course. They do not express physical properties themselves except in the limited sense of telling us how many times as great something is in one case than in another. This is an important point. It is like the difference between density and specific gravity. It is possible to so choose the electric and magnetic units that $\mu=1$, $c=1$ in ether: then $\mu$ and $c$ in all bodies are mere numerics. But although this system (used by Hertz) has some evident recommendations, I do not think its adoption is desirable, at least at present. I do not see how it is possible for any medium to have less than two physical properties effective in the propagation of waves. If this be admitted, I think it may also be admitted to be desirable to explicitly admit their existence and symbolise them (not as mere numerics, but as physical magnitudes in a wider sense), although their precise interpretation may long remain unknown.

Digitized by Google

If, for example, **H** be imagined to be the velocity of a substance, then $\frac{1}{2}\mu H^2$ is its kinetic energy, and $\mu$ its density. And if **E** be a torque, then $c^{-1}$ (the elastivity) is the corresponding coefficient of elasticity, the rigidity, or *quasi*-rigidity, as the case may be; whilst $c$ is the coefficient of compliance, or the compliancy; and $\frac{1}{2}cE^2$ is the stored energy of the strain.

§ 24. Besides influencing the values of the ether constants as above described, we have also to admit that in certain kinds of matter, when under the influence of electric force, energy is dissipated *continuously*, besides being stored. These are called electrical conductors. When the conduction is of the simplest (metallic) type, the waste of energy takes place at a rate proportional to the square of the electric force. Thus, if $Q_1$ be the Joulean waste,

$$Q_1 = k\mathbf{E}^2 = \mathbf{EC}, \qquad (8)$$

if

$$\mathbf{C} = k\mathbf{E} \qquad (9)$$

This new flux **C** is the conduction current, and $k$ is the conductivity (electric). Its reciprocal is the resistivity.

The termination-ivity is used in connection with specific properties. It does not always sound well at first, but that wears off. Sometimes the termination ancy does as well.

The conductivity $k$ is constant (at one temperature), or is a linear operator, as in the previous cases with respect to $\mu$ and $c$. The dissipation of energy does not imply its destruction, but simply its rejection or waste, so far as the special electromagnetic affairs we are concerned with. The conductor is heated, and the heat is radiated or conducted away. This is also (most probably) an electromagnetic process, but of a different order. Only in so far as the effect of the heat alters the conductivity, &c., or, by differences of temperature, causes thermo-electric force, are we concerned with energy wasted according to Joule's law.

The activity of the electric force, when there is waste, as well as storage, is

$$\mathbf{E}(\mathbf{C} + \dot{\mathbf{D}}) = Q_1 + \dot{U} \quad . \quad . \quad . \quad . \quad . \qquad (10)$$

The sum $\mathbf{C} + \dot{\mathbf{D}}$ is the electric current, when the medium is at rest. When it is in motion, a further term has sometimes to be added, viz., the convection current.

§ 25. If a substance were found which could not support magnetic force without a continuous dissipation of energy, such a substance would (by analogy) be a magnetic conductor. Let, for instance,

$$\mathbf{K} = g\mathbf{H} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \qquad (11)$$

then **K** is the density of the magnetic conduction current, and the rate of waste of energy is

$$Q_2 = \mathbf{HK} = g\mathbf{H}^2 \quad . \quad . \quad . \quad . \quad . \qquad (12)$$

The activity of the magnetic force is now

$$\mathbf{H}(\mathbf{K} + \dot{\mathbf{B}}) = Q_2 + \dot{T} \quad . \quad . \quad . \quad . \quad . \qquad (13)$$

Compare this equation with (10). The magnetic current is $\mathbf{K} + \dot{\mathbf{B}}$.

As there is (I believe) no evidence that the property symbolised by $g$ has any existence, it is needless to invent a special name for it or its reciprocal, but to simply call $g$ the magnetic conductivity. The idea of a magnetic current is a very useful one, nevertheless. The magnetic current $\dot{\mathbf{B}}$ is of course real; it is the part **K** that is speculative. It plays an important part in the theory of the transmission of waves in conductors.

(*To be continued.*)

**Terrestrial Magnetism.**—M. Moureaux, of the Parc St. Maur Observatory, states that at 4 a.m., on January 15th, a violent shock of earthquake occurred on the coast of Algeria, and that at 4:15 a.m. on that day the magnetographic curve at the observatory was much disturbed. The amplitude of the oscillation did not exceed 1′·5. The bifilar and the balance instruments do not appear to have been affected like the declination needle.

## A NEW PRINCIPLE IN ELECTRO-METALLURGY.

No physical principle is new; all are co-existent with the matter and force of whose inter-relations they are the expression, but it is a defensible convention to use the term "new" when one of those relations is consciously recognised as distinct and coherent. As often happens, this particular principle with which we are concerned has been long in practice before its separate existence was suspected, but signs are not wanting that it will shortly receive—nay, is actually now receiving—the earnest study that will lead to speedy and wide application. Stated in the baldest form, it consists in the unique capability of electricity of furnishing a highly localised source of energy. Every arc lamp in existence is an instance of this capability; every eudiometer fitted with a pair of fused-in platinum wires used by the chemist in ordinary gas analysis is a practical application of the same fact. It may claim rank only second to the most striking of all the properties of electricity—that power of passing from the condition of low-pressure energy to high-pressure energy, which is precisely equivalent to the transformation of low-temperature heat to high-temperature heat, were that practicable, as at present it is not. Of utility almost equal to the *transformability* of electrical energy we may reckon its *compactness*.

An illustration of an extremely simple adaptation of the means thus provided to an industrial end is afforded by a recent German patent for a process and apparatus for superheating metals already fused. A glance at the accompanying figure (Fig. 1), which represents a longitudinal section of

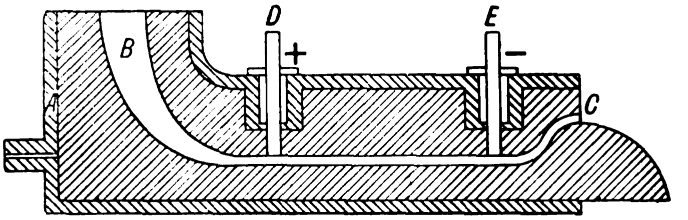

Fig. 1.—Apparatus for Superheating Molten Metal.

the apparatus, will show the plan adopted. A cast-iron box A, capable of being divided into two parts, is packed full of any suitable refractory material, such as sand, fireclay, or magnesia, and a channel B formed therein, funnel-shaped at the top, becoming parallel-sided when it has reached a horizontal position and taking an upward curve at C before the end of the box is reached. Two electrodes D and E pass through stuffing boxes packed with asbestos or some similar material at once capable of withstanding heat and of acting as an insulator. The metal to be superheated flows in at B, passes along the horizontal channel, serves as a conductor between D and E, and has its temperature raised thereby, and escapes at C. Consider the simplicity of such a method compared with any more usual mode of heating. With a common furnace fuel would have to be burnt in a refractory chamber surrounding the vessel containing the liquid to be superheated. If a continuous flow were required this vessel would take the form of a tube, through whose walls every unit of heat imparted to the liquid would have to be transmitted, while the surface from which radiation could take place would not be that of the tube itself but of the necessarily larger chamber surrounding it.

It is thus self-evident that where heat has to be applied to the interior of a vessel it is vastly more economical of energy to introduce it in the form of an electric current, convertible into heat on the spot where the heating is to be done, than to produce heat on the exterior of the vessel and transmit it through its walls. Whether it is more economical commercially is another matter. As long as the energy furnished by an electric current has to be derived from the combustion of fuel through the intermediaries—a boiler, engine, and dynamo—it must needs compete at a great disadvantage with the energy resulting from the direct combustion of the same fuel. But another factor here steps in which may turn the scale. Few materials can withstand the transmission of large quantities of heat at a high temperature, and the most refractory fireclay

soon fails when thus employed, the expense of renewal being considerable, and, in fact, the cause of failure of many important industrial enterprises. Nevertheless, it is not to be supposed that it would necessarily be commercially profitable to distil coal in a gas retort which was heated internally by the passage of a current instead of being fired externally in the usual way, though cheaper methods of producing electricity may yet make it so. Strange if the profitable manufacture of gas should come to depend on the aid of its hated rival!

But when we turn to the production of more costly commodities the case is altogether different. For the reduction of aluminium from its oxide it was tolerably certain that an extremely high temperature was necessary to give even a chance of success. When the Cowles' process was devised it first became practicable to attain such a temperature. By the happy device of conveying the energy to the centre of the charge before it became actual heat the problem was solved. The arrangement necessary for this was of the simplest description; as shown in Fig. 2, it simply consisted of two carbon electrodes A A′ passing through boxes B B′ filled with copper shot, and serving to maintain a sliding contact with them, into a rectangular box C, of firebrick, lined with refractory material (limed charcoal) so as to form a central cavity D for the charge. By this device loss by radiation is reduced to a minimum, the arc forming in the very heart of the charge, which can be surrounded by non-conducting material to any desired extent. The high price of aluminium alloys—for the Cowles' process is better adapted for their production than that of the pure metal—made it only of secondary importance that a costly transformation of heat into electricity had first to be performed; the advantage of being able to produce an enormously high temperature at the very spot where it was wanted outweighed all other considerations.

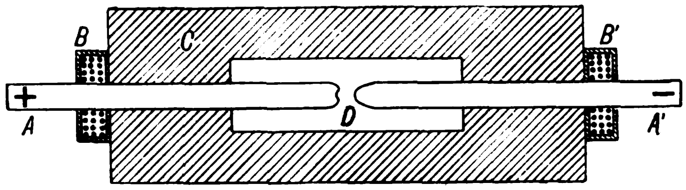

FIG. 2.—Arrangement of Electric Furnace in Cowles' Process.

It is most instructive to observe in how many different and independent minds the central idea of which we are endeavouring to give an exposition is working, or has worked, with fruitful issue. Appreciation of its value is not confined to the technologist. It has been applied to purely scientific purposes. Hempel, in a recent number of the *Berichte* of the German Chemical Society, has made use of it in the following way:—Being confronted with the fact that iron begins to soften at a dull red heat, thereby preventing its use for vessels for heating under pressure if the heat be applied to the exterior of the vessel, he succeeds in utilising that material for such purposes by conveying a current of electricity to the interior of the experimental vessel, and there converting it into sensible heat. A convenient arrangement of the kind is shown in section in the accompanying figure (Fig. 3).

A steel vessel A bored from the solid is fitted with a cover B screwing closely into it. A screw-down valve C provides means of communication with the interior. In the cavity of the vessel thus made is a porcelain tube D containing the substance whose behaviour under the combined influences of heat and pressure is to be studied. It rests on a cylinder of carbon E, which makes a sliding fit with the steel vessel in which it is. The upper end of the porcelain tube is closed by a slightly-coned plug F, also of carbon, and through this passes a carbon rod G, about $\frac{1}{8}$in. in diameter, reaching to the lower plug E, and connected above with a conductor H, also slightly coned, and kept from contact with the conical hole in the cover through which it passes by the ebonite bush K. The steel vessel itself serves as one electrode, being joined to the conductor L by the band M. The charge having been placed in the porcelain tube, the vessel closed, and any suitable gas pumped in till the desired pressure has been reached, the valve is shut and a current passed through the slender carbon rod G, thus heating it and the charge. The entire apparatus can be immersed in water if thought necessary, and the temperature approximately controlled by varying the current.

This apparatus, though primarily one suited for the needs of research, becomes indirectly of great technological importance. By its means the best conditions for the execution of technical processes may be worked out. In one special instance something in this direction has already been done. It is well known that a recently introduced and promising method of gold extraction depends on the solvent powers of alkaline cyanides upon gold. Cyanide of potassium, which is most generally used, is a somewhat costly substance, and a cheaper method of manufacture than that at present in use would greatly develop not

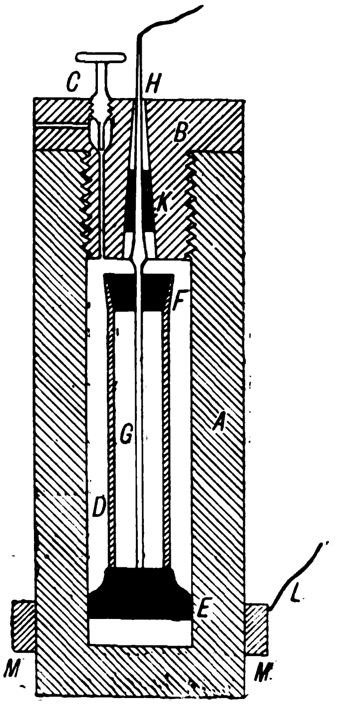

FIG. 3.—Apparatus for Applying Heat Gases.

only this particular process but many other industries. In the records of the attempts of previous experimenters to make cyanides cheaply, one is struck by the persistency with which failures are ascribed to the difficulty of obtaining sufficiently refractory material for the vessels in which to carry on the chemical reactions necessary. The most refractory fireclay soon became destroyed and its renewal was a serious expense. This was, of course, with externally fired retorts. The production of cyanides being, therefore, peculiarly a subject with which the apparatus described above is fitted to deal, experiments have been made on the direct synthesis of cyanogen from carbon and nitrogen under the influence of basic materials such as baryta and potassium carbonate, with the result that it was found that the latter was the better and, further that an increase of pressure greatly favoured the formation of cyanides. Here, then, is a direct instance of the application of the power of producing a temperature at once high and strictly local, which is so useful a property of a current of electricity, to a purpose of great industrial importance. Not only may the best conditions for large scale processes be thus ascertained, but such processes may themselves be executed by similar means.

Of the truth of the last statement there is ample evidence. A glance through the list of recent patents will show that inventors are already at work in this direction. Messrs. T. Parker and A. E. Robinson, of the Electrical Construction Corporation, have taken out a patent, No. 11,099 of 1889, for the production of carbon disulphide, which distinctly embodies this principle. The formation of carbon disulphide can only be effected by the aid of heat, the reaction

$$C + S_2 = CS_2$$

being endothermic, the quantity of heat absorbed being 19,610 thermal units. In consequence of this, the retorts in which the

Digitized by Google

reaction takes place have to be heated from without, with all the resulting disadvantages that have already been detailed. In the ordinary process an iron or fireclay retort filled with charcoal or coke is heated to redness, and sulphur dropped in through a tube from time to time. Combination takes place with absorption of heat, and the product passes away to a worm and is there condensed. In the new process, as described in the patent, wood charcoal is heated between carbon electrodes connected with a dynamo, and sulphur vapour passed through the heated mass. Thus the walls of the vessel in which the operation is conducted will be the coolest instead of the hottest part, and the loss of heat by radiation will be reduced to a minimum. Added to this is the important advantage that the vessel can be massively constructed, as no heat has to be transmitted through its walls, and will not need renewal as do the present retorts. In this case, the product the formation of which is desired is a highly volatile substance, and distils from the spot at which it has been brought into existence without extraneous aid. But by somewhat increasing the current used, or by diminishing the size of the vessel in which the reaction takes place, so that no part of it may be remote from the source of heat, substances of considerably less volatility may be similarly prepared and distilled. Such substances are the metals sodium, potassium and magnesium, for which a large and increasing demand exists. The same ingenious inventors have secured a patent, No. 11,707, of 1889, for preparing these metals by heating their oxides, hydrates and carbonates mixed with carbon by means of an electric current. The electrodes used are of iron, but the idea underlying the process is the same as that in the former patent. The chief expense encountered in the manufacture of sodium, until the Castner process came into use, was that caused by the destruction of the wrought-iron retorts necessary to withstand even fairly the high temperature required to reduce sodium carbonate by means of carbon. In the improvement just described no such expense exists. The process is precisely analogous with the Cowles' for the reduction of aluminium, with this important difference: aluminium being non-volatile, even at extremely high temperatures, remains in the focus of the operation of reduction, and there combines with the numerous impurities, all similarly reduced to their elementary state, and forms alloys with such bodies as iron and silicon, all far less valuable than the pure metal. In consequence, as has been already pointed out, aluminium itself cannot be economically produced in the Cowles' furnace, although its copper alloys are readily made. But sodium, potassium and magnesium are, when compared with aluminium, readily volatile, and they are therefore removed from the sphere of action as fast as they are formed. On *prima facie* grounds, therefore, there is reason to expect this novel process to prove a success.

Thinking upon the lines that we have endeavoured to indicate many other applications of this luminous principle suggest themselves. Messrs. Parker and Robinson have already in hand a large installation, the output of the dynamo being about, it is said, 700 electrical horse-power, at Wednesfield for the purpose of manufacturing phosphorus. Although details are not yet to hand, there is little doubt that the rationale of the process is the same as those already quoted. Phosphoric acid, or a phosphate mixed with charcoal, or other form of carbon, and heated by a current passed between carbon electrodes, would be decomposed, evolving vapours of phosphorus which could be led away and condensed in the ordinary manner. On the precise method and plant employed the smoothness and economy of working would of course largely depend, and of these we shall doubtless hear in due time, when it will be our duty to communicate them to our readers.

All these applications are practicable to-day with electricity at current prices, but a large reduction in its cost such as would result from any workable process for producing it directly by the oxidation of coal would open the door to still wider developments. No matter how low the price of the material manufactured, every process in which external heating is at present performed by the direct consumption of fuel would then be carried out by internal heating effected by the passage of an electric current though a medium of high resistance.

## ELECTRICAL STANDARDS COMMITTEE OF THE BOARD OF TRADE.

The following draft resolutions, with others, dealing with the practical measurement of power, whether developed by unvarying or alternating currents, will be submitted to the Electrical Standards Committee for discussion at their next meeting, which will take place on Friday, the 20th inst.

Board of Trade, February 10th, 1891.

1. That it is desirable that new denominations of standards for the measurement of electricity should be made and approved by Her Majesty in Council as Board of Trade Standards.

2. That the magnitudes of these standards should be determined with reference to the centimetre as unit of length, the gramme as unit of mass, and the second as unit of time, and that by the terms centimetre and gramme are meant the standards of those denominations deposited with the Board of Trade.

3. That the standard of electrical resistance should be denominated the ohm, and should have the value 1,000,000,000 in terms of the centimetre and second.

4. That the resistance offered to an unvarying electric current by a column of mercury of a constant cross sectional area of one square millimetre, and of a length of 106·3 centimetres at the temperature of melting ice, may be adopted as one ohm.

5. That the value of the standard of resistance constructed by a Committee of the British Association for the Advancement of Science in the years 1863 and 1864, and known as the British Association unit, may be taken as ·9866 of the ohm.

6. That a material standard constructed in solid metal, and verified by comparison with the British Association unit, should be adopted as the Board of Trade Standard ohm.

7. That for the purpose of replacing the standard, if lost, destroyed or damaged, and for ordinary use, one or more copies should be constructed, which should be periodically compared with the standard ohm, and with the British Association unit.

8. That the standard of electrical current should be denominated the ampere, and should have the value one-tenth (0·1) in terms of the centimetre, gramme, and second.

9. That an unvarying current which, when passed through a solution of nitrate of silver and water containing from 15 to 20 parts by weight of nitrate of silver in 100 parts of water, deposits silver at the rate of 0·001118 of a gramme per second, may be taken as a current of one ampere.

10. An alternating current of one ampere shall mean a current such that the square root of the time average of the square of its strength at each instant, in amperes, is unity.

11. That an instrument constructed on the principle of the balance, in which by the proper disposition of the conductors forces of attraction and repulsion are produced which depend upon the amount of current passing, and are balanced by a known weight, should be adopted as the Board of Trade standard for the measurement of one ampere, whether the current be unvarying or alternating.

12. That the standard of electrical pressure should be denominated the volt, being the pressure which, if steadily applied to a conductor whose resistance is one ohm, will produce a current of one ampere.

13. That the electrical pressure at a temperature of 62° F. between the poles or electrodes of the voltaic cell, known as Clark's cell, constructed and used in accordance with the specification attached to these proceedings, may be taken as not differing by more than——— parts in one thousand from a pressure of ——— volts.

## THE PELTON WATER-WHEEL.

It is as impossible to select any one kind of turbine as the "best-all-round" as to point to any one battery as being superior to all others. The volume and head of the water-supply not only vary as widely in different instances as do the volts and amperes of different dynamos taken at random, but Nature, who shows what she can do in forming blades of grass and grains of sand to uniform patterns, does not, unfortunately for the turbine maker, construct waterfalls to standard sizes. The design of turbines for low pressure is undoubtedly more difficult, by reason of the attention which must be paid to reduce skin friction, shocks caused by improper curvature of the blades, and eddies which may dissipate energy in the tail. High-pressure motors on a large scale are little known in this country, where mill streams are common and mountain torrents are rare. The pressure of the hydraulic service in London is too high for the direct driving of turbines, but for limited powers the Thirlmere water motor is well known, and consists of a set of buckets on the periphery of a wheel, the water impinging on them tangentially from a single jet. A similar wheel is coming into extensive use in America, and is specially adapted for the heads of from 100 to 1,000 or even 1,500 feet which are to be found in Canada. The design of the buckets, though more simple than that of a central-flow or inward-flow turbine, admits of definite mathematical treatment. The Pelton wheels (Fig. 1) employ round jets which strike the bucket fairly in the plane of rotation, and by means of a wedge-shaped division (Figs. 2 & 3) prevent the accumulation of idle water at the bottom of the pocket (Fig. 4), and discharge the water at a low velocity. The absence of joints and casing, of skin friction, and other matters which affect the useful results of low-pressure turbines, cannot be claimed as an advantage, because they need not exist with a motor intended for a considerable head. For electrical purposes a wheel which naturally runs on a horizontal shaft is preferable to one in which the water has to be brought round a bend in order to avoid a vertical shaft on which no dynamo maker would care to couple his armature. The Pelton Water Wheel Company have forwarded to the Niagara Falls Commission an estimate for wheels to develop 20,000 horse-power, of which four wheels to give 8,000 horse-power are for driving dynamos, and, as recorded in another column, have been awarded a fourth-class prize for their plans, no first prize being awarded. These wheels present an advantage in this case, since they would have to be placed in excavations in the solid rock, and would, probably, take less room than Girard turbines; and although the fall would not be sufficient to bring out their best qualities, they would certainly be much less

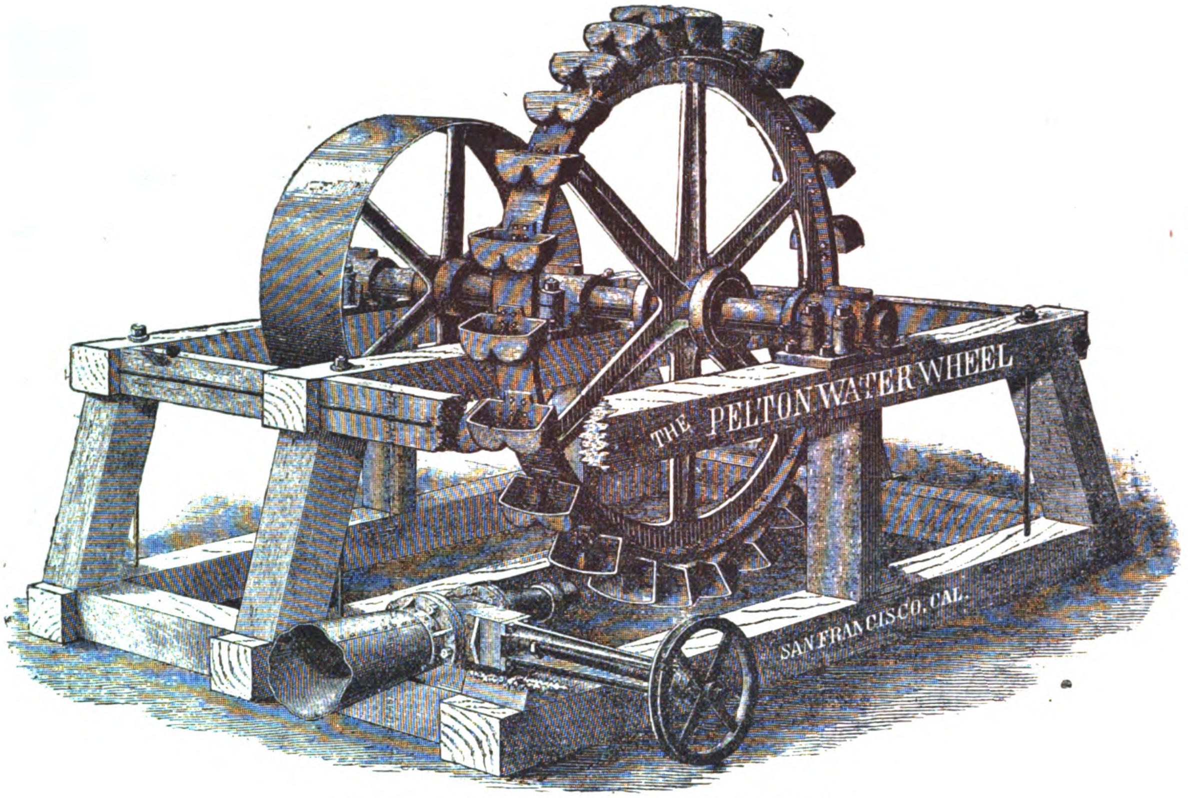

FIG. 1.—The Pelton Water Wheel. Cover removed.

Digitized by Google

troublesome to maintain under a head of 140ft. than most other kinds of turbines. The mining plant at Rock Creek, El Dorado County, California, is worked at a distance of two miles by a 100 horse-power Brush dynamo driven by an 8ft. Pelton wheel. The head is 110ft., the wheel runs at 100 revolutions per minute, the water flowing through a 5½in. nozzle, and it can deliver 130 horse-power. In another case, four Pelton wheels were used to drive Brush dynamos, using water which had already been used by other turbines in the immediate neighbourhood.

## TIGHT BELTS.*

BY ROBERT GRIMSHAW.

This is not to be an article advocating tight belts; rather one upon the tightness of belts, and complaining that belts are more often too tight for their good and for that of the shafts which they connect than too loose.

It is usually set down in text books, and in ninety-nine cases in a hundred in the "experience boxes" of men who call themselves practical, that the tighter a belt is (other things being equal) the more it will drive. I had the honour of being the first, so far as I know, to point out that this was true only to a certain extent; that there was a limit, with each kind of belt and each set of conditions, beyond which further tightening not only gave no further increase of driving, but actually lessened the capacity of the belt—to say nothing of the injurious effect upon belt, fastenings, and shaft bearings. What is that "slipping point," beyond which no further tightening will give more driving power? And why does it exist?

We had better answer the second question first. We know that the tendency of the pull on a belt is to bed it down to the face of the pulley, thus bringing more and more of the surface in contact with the pulley face, according as the tension is made greater and greater. A belt that is soft and flexible will, of course, bed down better than one which is not smooth and flat. The effect of bedding a soft surface down to the pulley face is to change its character. A surface which is comparatively porous, or rough, becomes smooth by the pressure, and with some kinds of belts takes on a sort of a glaze—only temporary in some cases, permanent in others. A glazed surface will not drive so well as one which is unglazed; and more harm may be done by glazing the surface, either temporarily or permanently, than can be balanced by the advantage of having the belt touch the pulley all over its surface. In other words, if, before excessive tension was resorted to, the belt touched the pulley with three-fourths of its surface, and if, after excessive tension was put on, it touched over the whole surface, we would expect one-third increase in the driving-power, as a maximum. But if the character of the three-fourths which touched the pulley before straining is so changed that each square inch of it is only as good as one-half square inch was before, we have the value of the three-fourths lessened to three-eighths, and this plus the new one-fourth, which we will assume is as good as any equal portion of the three-fourths, makes only five-eighths, which is not as much as three-fourths.

This is the theory of the thing, and it is simply borne out by tests made in a belt-testing machine and by experience with belts running in saw-mills, electric light plants and other establishments. It is more so with leather belts than with raw hide; more so with leather and raw hide than with cotton, and more so with cotton than with rubber. At least, this is the general run of things.

The moral of all this is to run your belts loosely; then you will be sure that you are not hurting them, while at the same time lessening their driving power. So long as a belt will start its driven pulley suddenly, it is tight enough for the work. It may be tight enough to run the job right along and yet not be able to start a machine from a state of absolute rest; particularly if there be heavy rotating parts which absorb power during quiet running, to give it out when needed to overcome a sudden excess of load. Of course, I do not mean that a belt should be run so loose that it would flap and weave; but so long as it runs quietly, and without slinging from side to side, it should be allowed to be as loose as it can be slacked up to, and yet drive the load. And if there be a flapping fold running from the driving to the driven side, it is much better to take it up by an idler pulley near the smaller of the two pulleys connected by the belt, than to take up the slack at the fastening.

Idler pulleys are great things if people will only distinguish between them and tighteners. An idler should in no way increase the strain at the fastenings; should in no way increase the pull on the bearings; that is the test. The minute that it does this it is not an idler, but a worker, and a mischievous worker. The proper way to apply an idler is so that it will increase the wrap on the pulley on which the belt drives the most poorly. (This is not necessarily the smaller of the two pulleys, for sometimes a small wood pulley will have more grip upon a belt than a large one of iron; sometimes a small iron pulley may be lagged with leather or paper so as to drive better than the larger one over which the belt runs.)

Of all the ways by which a belt may be made to drive more, giving it greater tension may be regarded as the poorest all around. Give it more arc of contact; give it better pulley surface, run it faster—do almost anything except increase its tension. Of course, increase of width or of thickness gives increase of driving power under similar circumstances, but that means another belt, and should not be resorted to so long as the simple means of giving more arc of contact, better surface to grip on, and greater speed, remain untried.

* From the *Electrical Engineer* of New York.

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**FRIDAY, February 13th.**

PHYSICAL SOCIETY.

*5 p.m.* Annual General Meeting, after which the following Papers will be read or discussed: 1. "Photo-Electricity," by Prof. MINCHIN. 2. "The Change in the Absorption Spectrum of Cobalt Glass produced by Heat," by Sir JOHN CONROY. Bart.

INSTITUTION OF CIVIL ENGINEERS.

*7.30 p.m.* Students' Meeting. Paper to be read: "The Cleaning and Deepening of Rivers and Canals by means of the Transporting-power of Water," by W. HERBERT WHEELER, S.I.C.E.

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse: "Some Results of Recent Eclipse Expeditions," by Prof. A. SCHUSTER, F.R.S.

**SATURDAY, February 14th.**

ROYAL INSTITUTION.

*3 p.m.* Afternoon Lecture: "The Forces of Cohesion," by LORD RAYLEIGH, F.R.S.

**MONDAY, February 16th.**

SOCIETY OF ARTS.

*8 p.m.* Cantor Lecture III. 1. "The Electric Transmission of Power." by GISBERT KAPP.

**TUESDAY, February 17th.**

INSTITUTION OF CIVIL ENGINEERS.

*8 p.m.* Ordinary Meeting. Paper to be further discussed: "Electric Mining-Machinery," by LLEWELYN B., and CLAUDE W. ATKINSON, A.MM.I.C.E.

**WEDNESDAY, February 18th.**

ROYAL METEOROLOGICAL SOCIETY.

*7 p.m.* Ordinary Meeting. Papers to be read: "The Great Frost of 1890-1891," by CHARLES HARDING, F.R.M.S; "On the variations of the Rainfall at Cherrapoonjee in the Khasi Hills, Assam," by H. F. BLANFORD, F.R.S.; "The problem of Probable Error as applied to Meteorology," by T. W. BACKHOUSE.

SOCIETY OF ARTS.

*8 p.m.* Ordinary Meeting. Paper to be read: "Methods and Processes of the Ordnance Survey," by Colonel Sir CHARLES WILSON, K.C.B., F.R.S.

ROYAL MICROSCOPICAL SOCIETY.

*8 p.m.* Ordinary Meeting. Papers to be read by Dr. W. B. BENHAM and T. B, ROSSETER.

OLD STUDENTS ASSOCIATION.

*8. p.m.* Ordinary General Meeting at Finsbury Technical College. Paper to be read: "From College to Factory," by DUNCAN PEARCE.

**THURSDAY, February 19th.**

CHEMICAL SOCIETY.

*8 p.m.* Ballot for the Election of Fellows.

**FRIDAY, February 20th.**

INSTITUTION OF CIVIL ENGINEERS.

*2 p.m.* Students' Visit to the Tower Bridge Works.

SOCIETY OF ARTS.

*4.30 p.m.* Popular Afternoon Lecture: "The Science of Colour," by Capt. ABNEY, F.R.S.

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse: "Infectious Diseases, their Nature, Cause and Mode of Spread," by Dr. ED. E. KLEIN, F.R.S.

**SATURDAY, February, 21st.**

ROYAL INSTITUTION.

*3 p.m.* Afternoon Lecture: "The Forces of Cohesion," by Lord RAYLEIGH, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

## TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.*
**It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

*Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xvii.) are accepted up to 4 p.m. on Thursday.*

## TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a speciality of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

## "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

*Early in each year is issued* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1890 Edition consisted of about 850 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

*The 1891 Edition is now actively preparing, and Subscription and Advertisement Orders, New Names, Corrections, &c., can be received.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

***All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" Printing and Publishing Company, who are proprietors of the well-known "ELECTRICIAN" Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.***

## STEEL-PLATE PORTRAITS

*Of W. H. Preece, F.R.S.; Michael Faraday; Sir John Pender, K.C.M.G.; Sir William Thomson, F.R.S. (Past-President of the Institution of Electrical Engineers); C. H. B. Patey, C.B. (Late Secretary of Telegraphs, G.P.O.); Dr. John Hopkinson, F.R.S. (Past-President of the Institution of Electrical Engineers); Dr. Oliver J. Lodge, F.R.S., and Prof. William Crookes, F.R.S. (President of the Institution of Electrical Engineers), have been issued as Supplements to* "THE ELECTRICIAN." *A few Copies of these admirably-executed Steel Engravings can be supplied, price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, post free, 4s. 6d.*

## ELECTRIC LIGHTING IN THE CITY OF LONDON.

WHEN it is remembered that the "City" was the scene of the first experiment in electric lighting on a considerable scale, some ten years ago, last week's ceremony in connection with its establishment on a permanent footing may well give rise to some curious reflections. All London can call to mind the spectacle they were invited to witness in the spring of 1881, when, at a given signal, the ill-lighted and generally deserted thoroughfares extending south and west of the Royal Exchange, along King William-street and over the Bridge, up Cheapside and down Ludgate-hill—to say nothing of the Thames Embankment—were suddenly bathed in a flood of light the like of which no man had seen before, and, as the event proved, no man wished to see again. From one point of view the problem of street lighting seemed to be solved; electricity, which had annihilated time and space, was now to obliterate the distinction between day and night. But from a more prosaic and practical point of view the exhibition was overdone and proved nothing, except, perhaps, that the new illuminant was apparently fickle, and certainly uncanny. Then when the price had to be named, and the aims of the experimenters more closely inquired into, there came the inevitable rebound; and although for some considerable time in portions of the principal streets electric standards continued to compete with the lowly gas-lamp, they never extinguished it, and finally left it for many years in undisputed possession.

Digitized by Google

Ever since the period to which we are alluding the City authorities have been, so to speak, pregnant with the electric light, and are only just now being safely delivered. Somebody who has been so unkind as to count up the Commissioners' Reports on the subject of electric lighting to the Corporation authorities finds that the number corresponds to the Church's Articles. Thirty-nine abortive attempts were at all events evidence of perseverance, and the Corporation seems to have finally accepted them also as proof of sound orthodoxy; for at length the necessary tenders were issued, contracts accepted, and the work is now begun. What has been the motive or the cause of this prolonged gestation we need not too closely inquire into. Some people allege that the oft-recurring Reports of the Commissioners served the same purpose as eggs at an election. Certain it is that they—the Reports—were always the occasion of a good deal of undignified and sometimes inodorous squabbling; but whatever may have been the real grounds of hesitation, certainly they were not those implicitly assigned by the LORD MAYOR at last week's municipal function. The City of London, though reputed slow in its general movements, has never been backward in spending money, and the fanciful picture of the civic authorities cautiously watching and profiting by the experience of similar undertakings elsewhere is one which only reminds us of those other long-drawn and highly-coloured artistic productions familiarly associated with his lordship's progression.

Turning, however, to the practical features of the scheme now auspiciously inaugurated, it may be freely admitted that in some important particulars the City is exceptional, and calls for special treatment. In the first place, early closing prevails generally for business of all kinds; offices are deserted soon after six o'clock, and the shops quickly follow their example. If we except those of the public-houses and tobacconists, hardly a window is to be seen shedding light on the pavement after half-past seven. On this account alone the contrast between the heart of London and the main arteries leading from it in every direction, where much business of a light-giving kind is still carried on to a late hour, is very marked. Add to this the fact that the foot traffic in the City after eight o'clock is very small, we have a comparatively deserted and peculiarly dark neighbourhood, comprising within its limits probably more wealth and treasure than are to be found in a similar area anywhere else in the world. Here distinctly is a call for better illumination. But it is chiefly, if not wholly, from the streets that this call is heard. Few, if any, of the shops require any sort of light except to show both burglars and police where the safes are kept. As for dwelling-houses, there are none. Thus it is that we find the Provisional Orders now obtained by the City of London relate chiefly to the lighting of the thoroughfares; and on this account, no doubt, it is that the conditions upon which they are granted differ in many respects from those imposed where the contractors may reasonably form high expectations of the profits to be derived from private customers. Then, again, having to rely upon the street lighting almost exclusively—at all events, for some time to come—the contracting engineers will have to hold themselves in readiness to meet the not infrequent, and some times quite unexpected, fogs which envelop the City in darkness, even at mid-day, and which will tax the resources of the supply stations to their utmost.

These circumstances, peculiar to the undertakings, are evidently taken into account by the framers of the Orders, which, in several material points, are more favourable both to the Local Authorities and to the undertakers than is usually the case. As regards the former, this is especially noticeable, and shows how powerful the City is to fight its own battles even against all the armoury of the Board of Trade. In some respects, indeed, the undertakers themselves have suffered for the same reason. Twenty-four years is laid down as the absolute term of the undertakings, after which period the local authorities reserve the right, upon due notice, to purchase on the terms specified in the Electric Lighting Act of 1888; this at all events in respect to public lighting. Private lighting is treated separately, and is to be acquired, if demanded, on such terms as the parties may agree upon, or be determined by arbitration. As the scheme covers the whole of the City from Aldgate to Temple Bar the private business will in time not be inconsiderable. Any place of business, we notice, situated within 25 yards from a distributing main may require the undertakers to supply light, and on terms which we consider rather favourable to the customer. The two companies, however, who have accepted all this responsibility are fully equal to it; or perhaps we should say fully able to attract enough capital to work the project satisfactorily. So far as we can judge of the terms of their contract there would seem to be a good margin of profit on the side of the contractors. If, as appears to be foreshadowed in the wording of the Provisional Orders, the two undertakings become merged into one, its chances of prosperity would be still more favourable. On one point at least we gladly agree with the LORD MAYOR, that although its delay has been great, the task, when accomplished, will be far better done than if it had been seriously attempted eight or ten years ago.

## NOTES ON THE ELECTRIC RAILWAY: HISTORICAL, STATISTICAL AND TECHNICAL.*

BY FRANKLIN LEONARD POPE.

It is only six years ago that an electric street railway was put in actual commercial service in the United States for the first time. This was in the city of Cleveland, O. Less than four months ago the American Street Railway Association held its annual meeting at Buffalo, and in his opening address the president made the following significant remark :—"I am so thoroughly convinced that electricity is the coming power for street railways (except on very heavy grades, where the cable is best suited), and that it will prove so effective as a means of rapid transit for cities, that I believe that this is the last convention that will ever seriously consider horses for the operation of street railways."

Few people have any conception of the enormous extent of city and suburban traffic in the cities of the United States. Statistics indicate that the street railways of the United States carry something like twice as many passengers as all the steam roads, and, moreover, it has also been found that the number of passengers increases from year to year in a much greater ratio than the population, which means, not only that more people ride, but that the same people ride more frequently each succeeding year. The transportation of this enormous number of passengers, probably not less than four or five billions, taking the whole country together, with safety, comfort, speed and economy, must be recognised as an undertaking of the most gigantic description. It is well worth our efforts to carefully consider the best means by which it can be accomplished.

The discovery that it is possible to produce continuous mechanical motion by the agency of the electric current is due to Michael Faraday. In 1831 Joseph Henry, then Professor of Natural Philosophy in the Academy at Albany, N.Y., and afterwards the distinguished secretary of the Smithsonian Institution at Washington, in a letter to Prof. Silliman, of New Haven, said: "I have lately succeeded in producing motion by a little machine which I believe has never before been applied in mechanics, by magnetic attraction and repulsion." Time has shown that Henry's moderate conception of the legitimate field of the electric motor was prophetically accurate, but his views failed to impress themselves upon the minds of his contemporaries. In the expectation that electricity would soon be the universal motive power, the problem of its utilisation was, during the next 10 years, attacked with great zeal by a considerable number of inventors. The earliest as well as the most meritorious of these was a Green Mountain village blacksmith by the name of Thomas Davenport. Some time since, while preparing a lecture to be

* Abstract of a Paper read before the New York Electric Club.

Digitized by Google

delivered before the Board of Trade, in Springfield, Mass., I accidentally learned that this inventor had constructed a model of an electric railway in Springfield more than 50 years ago, undoubtedly the very first appearance of the electric railway in the history of the world. The record of his career shows that Thomas Davenport was a man of no ordinary merit. Pursuing the occupation of a village blacksmith in Brandon, Vt., at that time an obscure country town, far removed from all main lines of travel and transportation, he had no sooner been shown as a curiosity the effect of Professor Henry's electro-magnet in lifting a blacksmith's anvil by the magnetic power generated by three small battery cells then he was seized with the idea that electro-magnetism might be applied to the propulsion of all kinds of machinery, and, in fact, might be made a universal motive power. From that moment his whole life was devoted solely to the realisation of this conception. We must remember that at that time the steam engine was a comparatively uneconomical, inefficient, and dangerous apparatus, and was regarded at best but as a necessary evil; a thing to be tolerated and endured in the absence of available water power, but best dispensed with altogether wherever possible. At that date and for years afterwards the annual catalogue of disasters by fire and explosion due to the use of steam was a lengthy and horrifying one. With such facts as these in mind it is easy to understand why the possibility of a new motor, compact, noiseless, manageable, free from all danger of fire and explosion, should be hailed with enthusiasm as a priceless boon to the industrial community. We must remember, too, that there existed at that time no data from which could be foreseen or determined, even with remote approximation, the relative economy of steam and galvanic power. It was not until 10 years later that the great law of the conservation of energy and the correlation of the physical forces—now familiar to every schoolboy—was first formulated by Grove and Mayer and Joule; a law now so interwoven with our scientific conceptions that it is hardly possible for us to imagine that it could ever have been unknown. At a much later date than that of which I am now speaking, men whose names will be recognised as the foremost scientists of the time, such men as Lardner, Jacobi, and Joule, did not hesitate to put upon record the belief that within a few years the power of steam would be wholly superseded by that of electro-magnetism, and the *Scientific American* was publishing illustrated description of perpetual motion machines.

From the moment in which he first witnessed the experiment of lifting an anvil by Henry's electro-magnet to the very last hour of his life, Davenport never once wavered in his belief that steam was ultimately destined to be supplanted by electro-magnetism. Within six months from that time, with the assistance of another mechanic of the same town, he succeeded in constructing a machine by which he obtained continuous rotation by electro-magnetic power. During the six years between 1835 and 1841 he built more than 100 operative electric motors, scarcely any two of which were of the same design, and which varied in size from a small model up to an engine capable of driving a rotary printing press for 12 hours in succession. In December, 1835, he exhibited in Boston the model of an electric locomotive and circular railway which he had built in Springfield, and a similar though more finely finished model, which was built by him the following year, is still in existence in a good state of preservation. He published in 1840, now more than 50 years ago, in the city of New York, a weekly journal called the *Electro-magnet and Mechanics' Intelligencer*, which was printed upon a press driven by an electro-magnetic engine. Some of his motors, constructed as early as 1837 and 1838, were admirably designed, and in essentials, even to the shunt-winding, differed but little from some of the most advanced and successful types in use at the present day. Less than a year before his death, upon reading a newspaper account of the trial of the large engine built at Washington by Prof. Page under an appropriation from Congress, Davenport wrote a long and interesting letter to a local newspaper, congratulating Prof. Page upon his success, giving a concise but full account of his own work, and predicting with an earnestness born of entire conviction the ultimate triumph of electro-magnetism over steam.

It has been the fashion to smile at such men as Davenport as enthusiasts. Yet if Davenport was an enthusiast, so are we all enthusiasts as respects our anticipations of the realisation of the result which he predicted and for which he wrought unceasingly. Steam is nothing more than a convenient agency for the *transmission* of power, which derives its energy from heat and imparts it to mechanism. So soon as the great riddle of the day has been read—the production of electricity, as steam is produced, directly from heat—then, indeed, will the predicted triumph of electro-magnetism over steam become an accomplished fact. Forty years have passed away since all that was mortal of Thomas Davenport was laid to rest beneath the Brandon elms, yet I think there are not many present in this audience to-night who do not cherish the expectation, if not the conviction, that before the half-century has been completed the great problem will have been solved, and the era of a new industrial revolution will have dawned upon the world.

The electric locomotive constructed by Prof. George G. Page, which was tried by him on the Baltimore and Ohio Railroad, in 1851, deserves a passing notice here. It was a noteworthy achievement, but developed no new principle, nor did it contribute anything to the ultimate solution of the problem of the electric railway. Many other promising experiments were made, but all resulted in failure, until the very name of electro-magnetic motor became almost a synonym for "humbug." The electric motor, therefore, remained, for something like 40 years after its invention, an interesting but practically useless philosophical toy. It was like half of a pair of scissors—of no earthly use without the other half. The other thing that was needed was an organised machine which could convert large quantities of mechanical power into electricity. The discovery that it was possible to effect this conversion was also due to Faraday. With his usual sagacity he had suspected that it might be done, and undertook a series of experiments for the express purpose of finding out. On the second day he wrote to a friend: "I think I have got hold of a good thing, but cannot say; it may be a weed instead of a fish, which, after all my labour, I may pull up." On the tenth day he pulled it up, and it was a *fish*; it was not a small fish either. This was the beginning of the development of the magneto-electric generator. The next step is due to the genius of another American scientist and inventor, one whose name will occupy a far more prominent position in the annals of American science a century hence than it does to-day, Moses G. Farmer. He it was who, in 1867, in a letter to Henry Wilde, of Manchester, first described the principle of the modern dynamo-electric machine. Almost at the same time similar machines were independently invented by Wheatstone and Varley in England, and by Dr. Siemens in Berlin.

The earliest field of usefulness of the dynamo machine was found in arc lighting. One of the most effective of the early machines was designed by Gramme, of Paris, in 1872, and a number of them were shown by him at an industrial exhibition at Vienna in the following year. Here occurred one of those extraordinarily fortunate incidents which again and again have played such a prominent part in the history of industrial progress. In making the electrical connections to one of these machines not yet belted to the engine shaft, a workman attached to it by mistake a pair of wires which were already connected with another dynamo machine which was in rapid motion. The second machine instantly commenced to revolve. When the attention of Gramme was called to this phenomenon, he saw at once that the second dynamo was performing the function of a motor, and that what was taking place was the actual transference of mechanical power through a small wire by the means of electricity. This singularly opportune occurrence being commented upon in the scientific journals led to the almost instant recognition of the true place of the electric motor in the domain of mechanics.

The principle of converting mechanical energy into electricity and reconverting this by a reversed dynamo into mechanical power naturally suggested the practicability of transmitting power through electric wires to any required distance. One of the earliest results of this conception was the revival of the electrically operated railway, the commercial development of which had necessarily remained in abeyance until machinery was available for furnishing large quantities of electricity at a moderate cost.

The credit of priority in the invention of the electric railway in its modern form, that is to say, the moving electromotor on the car connected by electric conductors with a stationary dynamo, I believe to be justly due to Stephen D. Field, now of Stockbridge, Mass., who was living in San Francisco in 1877. This was about the time of the introduction of the cable system of street railways into San Francisco. Observing the operation of the cable road, it at once occurred to Field that electric power might be applied to the same purpose with as great or even greater advantage. At that time no dynamo-electric machines suitable for this purpose were to be had in the United States, and he accordingly ordered one from Europe for experimental purposes. It took a long time to make it, but at last it was completed and shipped to San Francisco by a sailing vessel. The vessel was wrecked on the voyage, and the machine went to the bottom of the sea. Not yet discouraged, he ordered another one, which eventually reached him in good order, and enabled him to commence his long-delayed experiments. He tried first an electric elevator, in which he was successful. In 1879, having exhausted his resources, he came to New York, bringing with him his plans, with which he hoped to enlist capital to continue his work. He laid these plans before me, and, being impressed with the entire practicability of his scheme, I gave him every encouragement in my power. The plan which he had devised contemplated the enclosing of the conducting wire in a conduit beneath the street. He was not successful in obtaining sufficient means to properly develop his invention; he became involved in tedious, harassing, and expensive litigation with wealthy Corporations, and his health failed him at a critical time, so that for years he was incapacitated from active work, but the single railway which is in operation in this country to-

Digitized by Google

day, and embodies his matured conceptions, is regarded by competent judges as in many respects superior to any yet brought before the public. Field's electric locomotive was first exhibited at the exhibition of railway appliances in Chicago in 1883, during the continuance of which 27,000 passengers were transported by it. In the summer of 1882, Dr. Joseph R. Finney exhibited in Allegheny, Pa., an electric street-car, for which the current was supplied by a copper wire, about the thickness of a lead pencil, 15 or 20ft. above the street. A small trolley fitted with grooved wheels, running on this wire as on a track, and connected with the car by a flexible conducting cord, served to convey the electric current from the suspended conductor to the motor. Some of the earliest of the successful lines in this country were arranged upon this plan.

The problem of the underground conduit does not at first sight appear to be a very difficult one, but without going into details it is sufficient to say that the conduit system has been tried on an extensive scale in Denver, Cleveland, and Boston, and to a lesser extent in several other places, but in every case the continual interference and interruptions consequent upon its use have exhausted the patience of the travelling public and compelled its abandonment. I do not wish for one moment to convey the impression that the problem is an insoluble one. My attitude is rather that which was taken by Prof. Tyndall some 10 years ago upon the question of the practicability of domestic electric lighting by incandescence. He had no doubt that the problem would be solved, but it was a great satisfaction to him to know that it would have to be done by somebody other than himself.

The storage battery system, both from the standpoint of the public and the street-car manager, is an ideal solution of the problem of electrical transportation. It has many features which especially commend it for city work. Each car is an independent unit, and hence no accident can materially cripple a well-organised system. The idea of being able to store a large quantity of electricity in a box under the seats of a car, to carry it around, and to draw from it a large amount of power, as required, is a most attractive one. Storage battery cars can be introduced in the existing systems, one car at a time. In cases of emergency they can be run over almost any route where a horse car can be run, not being restricted to the route of an electric conductor, and under ordinary circumstances the car can be run just as rapidly and controlled just as effectively as it can be with the trolley system. All these advantages were recognised at an early day, and hardly had the storage battery been invented before it was applied to street-car propulsion. The first storage car was operated in Paris in 1882. The system was then put in practical service on one of the lines in Brussels, and continued for two years. It was also introduced in 1886 on the Madison-avenue line in New York, and has been in operation there ever since. The results of the ten cars now running on the Madison-avenue line appear to have demonstrated that the system may, with careful management, be made thoroughly reliable. Each car will carry a full load on a straight and level track 15 miles per hour, and will ascend grades not exceeding 5 per cent. and not more than 500 feet long at five miles per hour. A run of 40 miles can be made on a level track, which is considered a half-day's work, with one charge of battery. The time required to replace the exhausted batteries with fresh ones is not more than two minutes.

There are, however, two serious objections to this system which have thus far been sufficient to prevent its adoption in other than exceptional cases. One of these is the great weight of the batteries, and the other is the lack of reserve power in the emergencies which sometimes occur. In other words, two considerations enter into the question, one of economy and the other of efficiency. To take up the question of comparative efficiency first, a very little consideration of the matter will show that the progress of the art, so far as yet developed, practically limits the use of storage battery cars to lines having very light grades—not more than 5 per cent. at the outside. Very many of our eastern cities, for instance, Springfield, Providence, Worcester, Albany, Troy and many others which I might mention, have very severe grades, from 7 to 10 per cent., and some of them half a mile long. To start a heavily loaded car in bad weather on such a grade as this means an expenditure for a few seconds of from 50 to 80 horse-power. Experience has shown that this is far too heavy a tax upon the powers of a storage battery. Even on comparatively level lines, in our northern climates, the occurrence of a heavy storm of snow or sleet necessitates the expenditure of an abnormal amount of power, and it is on just such occasions as these when everybody wants to ride, so that the cars are loaded to their utmost capacity, and great dissatisfaction prevails if there is any delay or any lack of sufficient accommodation. It is at such times as this that the advantages of a distribution from a central station are most apparent. The whole number of cars, or extra ones if necessary, can be run, and any amount of power required to force them through obstructions and to keep them running on schedule time can be supplied from the power station. It is merely a question of burning more coal. Considering the economical aspect of the question, first, as to the original cost, it may be said roughly, the difference between the storage and overhead line system is not very great; but the best authorities seem to concur in the opinion that it requires, roughly speaking, nearly twice as much power per unit of useful work done, with the storage battery system, that it does with the direct distribution system. The dead weight of the battery is nearly equal to that of a paying load of 30 passengers, and this load must be transported whether there are any passengers or not. The increased weight adds to the cost of renewal and repairs, both of the track and of the cars. The cost of horse-power for drawing cars has been found by long experience to vary from 10 to 11 cents per car per mile. The cost of power for the 10 storage battery cars on the Madison-avenue line in New York is said to figure out 10·6 cents per car per mile, practically the same as horse-power. A careful computation of the average cost of power by the direct distribution system, on a considerable number of different lines in this country, shows that the cost for coal, attendance, real estate, oil and waste, repairs of machinery and line, foots up 5·09 cents per car per mile.

I once had occasion to study this whole question very minutely. In the fall of 1886, when the West End Street Railway Company, of Boston, was first organised, I was commissioned by President Whitney to make for him a careful investigation of the subject of electric propulsion, which he desired to apply to the entire street railway system of Boston. It was a gigantic proposition, for at that date there was hardly a dozen electric street-cars running in this country. I was told by him at the outset that I must confine my researches to conduit and storage systems; that anything in the shape of an overhead line was out of the question and would never be tolerated in Boston for a moment. I submitted my report to Mr. Whitney on April 30, 1887. At that time no experience had been gained which would enable me to compute accurately the cost of operation of the different systems, but the final result of my estimate then given to Mr. Whitney, of the cost of power per car per mile, was as follows:—

| | |
|---|---|
| Horse-power | 11·07 cents. |
| Electric storage system | 7·34 „ |
| Electric underground distribution | 6·02 „ |
| Electric overhead distribution | 3·28 „ |

It will be seen that these figures estimated the cost of the storage system as a little over twice that of the overhead system. Experience has confirmed the substantial accuracy of my original estimate in respect to relative cost. The absolute cost for all electric systems is considerably greater than was anticipated. This is partly due to the item of repairs for the electric motor and gearing, which are found to be subject to much greater wear and tear than experience had given reason to anticipate, and partly to the great increase in the number of passengers per car mile, caused by the popularity of the electric cars, which adds greatly to the loads carried. Mr. Whitney then authorised me to construct an electric car operated by storage batteries, and to give the practicability of the scheme a thorough test. This pioneer car, the very first electric car of the West End Company, was put in service in the early part of October, 1887, and was run for some time between Cambridge and Boston. A careful series of tests and measurements showed the cost of operation to be about the same as that of a horse car of equal capacity. The West End Company continued to experiment, putting down the next year an expensive conduit line on Boylston-street, in Boston, and an overhead line on the extension of Beacon-street in Brookline. The comparative results of the practical trial of the three systems was so favourable to the overhead line that the objections of the citizens of Boston were gradually overcome, and at length overhead wires were permitted to be placed in the streets of the city proper.

Are electric railways dangerous? With a view of getting at the actual facts in the case, the *Boston Advertiser*, a few months ago, sent out a circular letter asking information from every city in which electric railways are in actual operation, from Portland, Me., to Galveston, Tex. Replies were published from 64 cities and towns. All but four of them were favourable. Not one solitary instance of accident or serious injury from electric currents was reported.

The average speed of the horse car is about six miles per hour. The question is sometimes asked, How fast may electric cars be safely run in a city street? At first the cable cars were run at the rate of seven miles per hour; afterward the speed was increased to 9½ miles per hour. The records show that there are not so many accidents under the present arrangement as there were before. The schedule rate of the electric cars in Cleveland is nine miles per hour, and in some parts of Boston as high as 12.

Limitation of time does not permit me to mention more at length the work of other American inventors, to whom the development of the electric railway is largely indebted. Among them are Charles J. Van Depoele, of Chicago, now with the Thomson-Houston Company at Lynn, who exhibited a car in operation in

Digitized by Google

Chicago in 1883; Leo Daft, whose motor drew a full-sized passenger car over the Mt. MacGregor Railway at Saratoga in 1883; and especially Lieut. Frank J. Sprague, who designed, carried out, and completed the first installation of electric railroading on a large scale in the world, in Richmond, Va., in 1888. This was a road 12 miles in length, with a great number of curves, a bad track, numerous grades of 10 per cent. and over, and an equipment of 40 motor cars. Labouring under enormous difficulties and drawbacks, Lieut. Sprague succeeded, by the completion and operation of this plant, in establishing beyond peradventure the future supremacy of the electric street railway, and many of the characteristic features at that time designed and introduced by him have practically become standards in the modern system, and are found in nearly every one of the thousands of cars now in service. The limits of time also compel me to content myself with the briefest possible reference to the most important development of electrical transportation which has yet come before the public: the electric underground railway. This undertaking having been placed in the hands of electrical engineers whose competency cannot be questioned, and backed by ample capital, has proved in London a phenomenal success. We are now assured that a syndicate of the most prominent capitalists of New York have undertaken to establish a system of transportation upon the same plan, consisting of a network of tunnels at a depth of 100 feet beneath the surface, and connecting all important points not only in the city itself, but in the adjacent sections of Long Island and New Jersey. Such a system would admit of the running of solid trains at very short intervals through the city, to and from all points in the suburbs, in every direction, and I venture here and now to predict that within the next 20 years, if not the next 10 years, electrical underground transportation will be brought to such a state of perfection that a passenger entering one of the central stations of New York may be deposited at his home station at any point within a radius of 10 miles in 15 minutes' time and at a fare of five cents. And this magnificent result is to be the contribution of the electrical engineer to the convenience and the prosperity of the public.

## ELECTRICITY IN THE FRENCH NAVY.*

BY M. FORIS.

At the present time, when electricity is about to extend the sphere of its operations on board ship by working most of the delicate and complex machinery now to be found there, it may be of interest to sum up in a few words the results which have been achieved during the first period of its utilisation on modern men-of-war, a period which was inaugurated some fifteen years ago by the introduction of the electric light.

The first lenticular projector was placed on board the Emperor Napoleon's yacht, the "Reine Hortense," in the year 1867. Soon afterwards a similar light was installed on the armoured frigate "L'Heroïne," and in 1870 the cruisers "Forbin" and "Destrées" were also fitted with electric light projectors. The generator was the Alliance magneto machine. In 1873 and 1874 the Russian naval authorities, who had closely followed the progress of the new illuminant, had projectors and Gramme dynamos fitted on board the ironclad "Peter the Great" and the Imperial yacht "Livadia." These machines were the first electric lighting Gramme dynamos ever built. In 1877 the French naval authorities again took up the question, and experimented on board the ironclads "Richelieu" and "Suffren," with lenticular projectors and gramme dynamos driven by Brotherhood engines. The improvements now brought about in the construction of dynamos and projectors resulted in electric search-lights becoming part of the regular equipment of our own and of foreign men-of-war. External electric lighting, rendered an absolute necessity owing to the rise of torpedo warfare, thus preceded interior electric lighting by several years. In 1881 the incandescent lamp was first revealed to the public at large by the Paris Exhibition of that year. In 1883, two years later, the French naval authorities were the first to make use of the incandescent light on board the "Redoutable," at Toulon, where 200 eight candle-power Swan lamps were arranged, three in series, and run off Gramme machines, driven by Brotherhood engines. The light was sufficiently successful to cause the authorities to decide to fit 300 lights on the ironclad "Richelieu," the dynamos being driven by high-speed Mégy engines. These early installations, very considerable for that time, were carried out by MM. Sautter-Lemonnier.

The advantages which the electric light possesses over oil and candle lighting for man-of-war work are as follows:—(*a*) Diminution of the staff required to look after the lighting of the ship; (*b*) greater security against fire; (*c*) the many dark and badly-ventilated corners of a modern battleship may be thoroughly illuminated without fear of the atmosphere being rendered unbearable; (*d*) suitability to night signalling.

On a man-of-war, as elsewhere, an electric light installation consists essentially of generators of electricity, mains and lamps, but the conditions imposed are very different from those generally met with on land. The first necessity to be complied with on board a modern man-of-war, namely the compactness required by the very small space available, rendered belting, driving, and slow-speed engines out of the question. The result of this was the creation of a special type of engine, such as the Brotherhood or Mégy, driving the dynamos direct, and running at 1,000 to 1,500 revolutions a minute. In the early days, when a few projectors, each run off a separate dynamo, were all the electric lighting there was, such apparatus sufficed. But as time went on the projectors increased in number, and incandescent lighting was introduced. Larger dynamos had to be built, until at the present day the lighting of a large ironclad requires the expenditure of at least 100 horse-power. For the early plant we have now substituted slow-speed compound-wound dynamos running at about 350 revolutions and driven direct by vertical engines, which are more powerful and more economical, using only from 28 to 33 pounds of steam per E.H.P. hour for an initial pressure of 70lb. to the square inch. The dynamo adopted most widely in the French Navy is the Gramme multipolar machine, though at the present moment we are returning to the two-pole type, as being equally efficient, stronger, and less liable to get out of order.

Within the last few years the Desroziers dynamo (see *The Electrician*, Vol. XXI., p. 762) constructed by the firm of Bréguet has also come into use. In this singular machine the Gramme ring is replaced by a flat disc, upon which the coils are wound, rotating between field magnets whose polar extensions are parallel to its axis. This ingenious dynamo works satisfactorily. Two ships, the "Formidable" and the "Forbin," have had two years' experience of the Desroziers dynamo, and it may be safely said that it has all the good points of other types at present in use in the French Navy, and is moreover lighter, better ventilated, and efficient. The Desroziers machine possesses the extremely valuable feature of retaining a high efficiency on a light load. On board ship a 150 or 200 ampere machine has a normal load of 80 to 90 amperes, so that this property of the Desroziers dynamo is of genuine importance, and it may be said that, other things being equal, this machine is the most economical of any in use on the ships of the French Navy.

The methods employed by the two leading firms to connect the dynamo and the engine merit special attention. MM. Sautter-Lemonnier couple the armature spindle to the engine by the intermediary of springs. The coupling is rigid and little liable to give way, but it is difficult to get at. The firm of Bréguet employ M. Raffard's ingenious coupling. This device consists essentially of two discs, one keyed to the engine shaft, and the other to the dynamo shaft. Upon these two discs are fixed an equal number of studs, arranged in two circles of unequal diameters, each pair of opposite studs being connected together by india-rubber bands. This elastic coupling in addition to its security and convenience has the advantage of insulating the dynamo from the engine.

Whatever else they may do, the engines employed on board ship in connection with the electric lighting must possess the following points: (*a*) Lightness and compactness; (*b*) parts easily accessible; (*c*) economy in steam consumption; (*d*) regularity of running; (*e*) ability to stand damp and heat without injury; (*f*) little attention required when running.

These diverse requirements are by no means easy to combine in a single engine, but French constructors have achieved success. It may be remarked that the difficulties of construction are greatly augmented by the necessity of adapting these plants to the ever-varying conditions brought about by the progress of artillery and metallurgy.

The latest style of engine brought out by MM. Sautter-Lemonnier is of the horizontal tandem type, only 3·6ft. high, and installed on board the cruiser "Davout." On the cruisers of the "Troude" class the combination shown in the accompanying illustration is used. This combination is 4·6ft. high, and is placed between decks below the water-line. For torpedo boats of the "Agile" class, the firm of Bréguet employ a single-cylinder vertical engine, driving a Desroziers dynamo mounted on the same bed-plate. This combination weighs 1,540lb., and has an electrical output of 3,500 watts (70 volts × 50 amperes), the space occupied being 3·8 × 4 × 2·4ft.

Whatever the class of vessel, electrical distribution is carried out at the standard pressure of 70 volts. This particular voltage has been fixed upon as the most suitable for circuits on which there are both arcs and incandescents. Experience has shown that the switching in and out of the projectors does not materially affect the internal lighting. The combination of the two kinds of lighting is only of recent origin; but its importance is very great when we

* From *Le Génie Civil.*

Digitized by Google

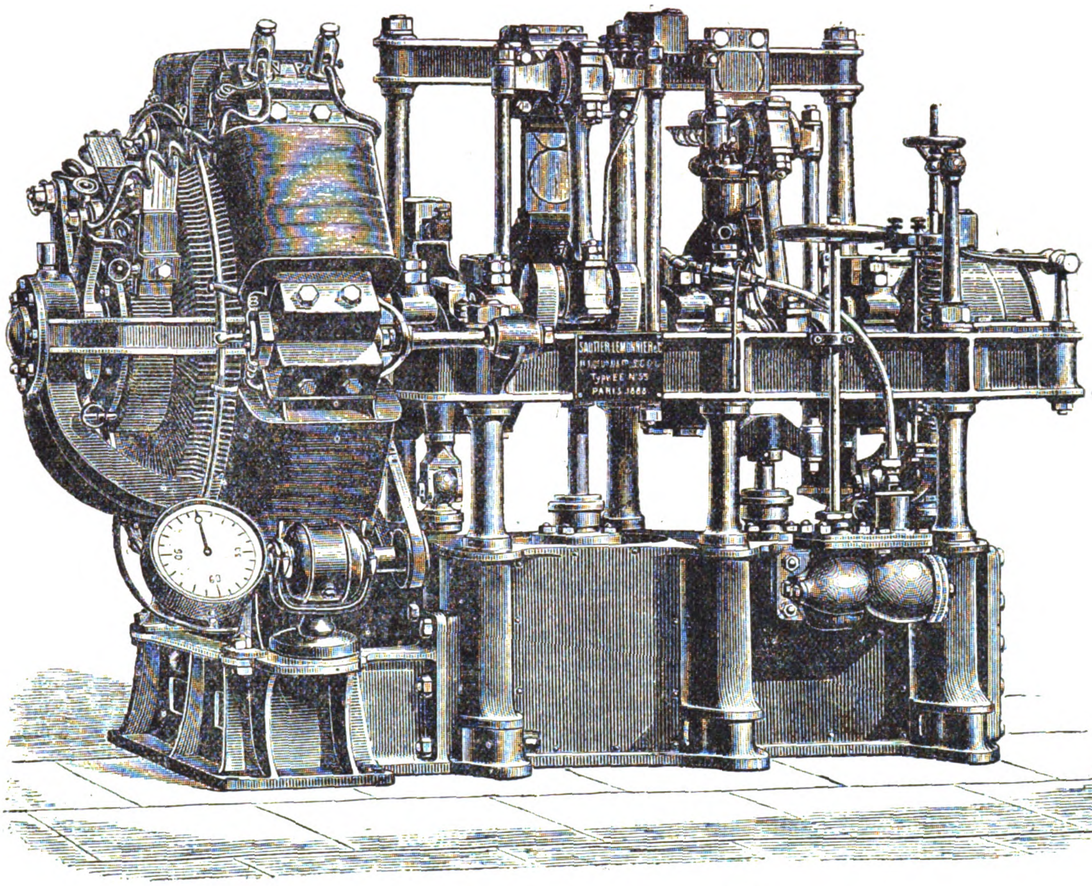
consider that on men-of-war the projectors absorb almost as much power as the incandescents.

The electric lighting system of a modern man-of-war is divided into two main divisions, viz., the internal lighting and the external lighting. The internal installation comprises (*a*) the all-day circuits, namely, those lighting the coal bunkers, passages, men's quarters, &c., in short all those portions of the ship into which daylight never penetrates ; (*b*) the night circuits, which include all parts where daylight penetrates ; (*c*) the sea-circuits, engine room, &c. ; (*d*) the fighting circuits, turrets, shot hoists, powder magazine, &c. The external installation comprises (*a*) the projector circuits, (*b*) the signal circuits, (*c*) the side-light and head-light circuits, (*d*) the miscellaneous circuits. The internal system is moreover divided into starboard and port circuits. The generating plant is usually divided into two groups, arranged under the protective deck, one forward and the other aft. Each group is joined up to special distributing boards which are in turn joined to each other. Hence it is possible to run the forward machines and manipulate the circuits from the other board and *vice versâ*, and matters are so arranged that any dynamo can be connected to any circuit.

One attempt was sufficient to cause the French naval authorities to renounce the employment of the shell of the ship as a return. Of course, the one great aim on board a man-of-war is to arrange matters so as to prevent anything like a complete breakdown of the light during an action. To attain this supreme object the port and starboard circuits are all joined across at intervals by connecting cables, so that when any portion of a circuit is damaged the lights are still supplied with current.

Great improvements have of recent years been effected in the construction of projectors ; they have become more powerful and more manageable, and the old hand-regulated apparatus has given place to one which can be worked automatically if required ; a great advantage when we consider that as many as half a dozen of these lamps are frequently simultaneously in use. The very latest improvement has been to enable the search-lights to be manœuvred from a distance. In future all the ship's projectors will be handled by one man, the captain of the ship perhaps, from the bridge. The electric current thus controls the illumination necessary for defence as well as the offensive armament. For defensive illumination in the immediate neighbourhood of the vessel projectors placed near the water-line and operated from within are now used.

The use of electricity as a motive power has already obtained considerable vogue on board ships, where ventilating fans so driven and little electric drills are becoming common. On the "Formidable" the electric drill has proved of great value. Quite recently a French naval constructor has succeeded in devising a satisfactory method for operating naval gun-carriages by electric motors, and their adaptation to pumps, hoists, and winches is only a question of time. Little by little we shall see the complicated, inefficient, and cumbersome hydraulic and steam pipes disappear from our battleships. Electricity will become supreme, and dynamos of 200 or 300 horse-power will be employed to supply power to the innumerable machines to be found on board a modern man-of-war.



Sautter-Lemonnier Combined Engine and Dynamo for Naval Purposes.

## AN ELECTRIC WAVE MEASURER.*

BY C. GRAWINKEL AND K. STRECKER.

If from any cause the strength of a current in a circuit varies, he change always takes place more or less gradually, the current during the change taking all values intermediate between the original and final ones. This happens more or less rapidly, as may be determined by the self-induction and capacity of the circuit. If, for instance, in Fig. 1, A is the original, E the final value of the current, this change may take place in the time $t_1$ or $t_2$, and even in the same time $t_1$ the change may occur in various ways as shown by the curves in the figure. On telegraph lines such changes follow one another incessantly, and consequently a knowledge of their nature is of great value in this branch of electrical engineering. In many cases this knowledge can be arrived at mathematically, but even then a corroboration is necessary, and sometimes a correction of the calculation is found by experiment to be required. On the other hand, a calculation is often quite impracticable.

In general, one is concerned with the question of determining the current strength at any chosen moment, or the relation between current and time. If these values are plotted out as in Fig. 1, in a system of co-ordinates, wave-like curves are usually obtained. From this fact the apparatus described below has been termed an apparatus for measuring electric waves or, briefly, an electric wave measurer.

We have already several means of solving the question, such as for instance Messrs. Siemens and Halske's soot writer, and Frölich's method of setting out current curves ; but in these cases the current is always measured through its magnetic properties,

* From the *Elektrotechnische Zeitschrift.*

Digitized by Google

and it must be considered that a certain interval always elapses between the commencement of a current and the appearance of its electro-magnetic effects, particularly where the latter entail the movement of a body possessing any considerable amount of inertia. It is only when this interval happens to be so small as to be negligible that one has hitherto had a method free from the inertia of magnetism and mass.

Such a method is, however, easily found. If we insert in the circuit a resistance, having as far as possible neither self-induction nor capacity, and measure the potential difference at the ends of this resistance, the current strength is proportional to the difference of potential. The latter can be measured either by applying the two ends of the resistance to an electrometer, or by connecting them to the terminals of a condenser, which is afterwards discharged through a galvanometer. Care has only then to be taken that connection with the two ends of the resistance is made at the proper moment.

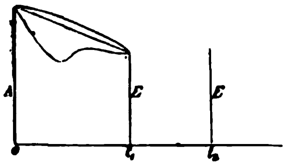


FIG. 1.—Time-current Curves.

This principle is not new, but has frequently been used for ends similar to that now in view, as, for instance, lately by Searing and Hoffmann in the determination of the form of the waves in an alternating current (*Journal* of the Franklin Institute, vol. 128, p. 93, and Fortschritte der Elektrotechnik, 1889, No. 2377).

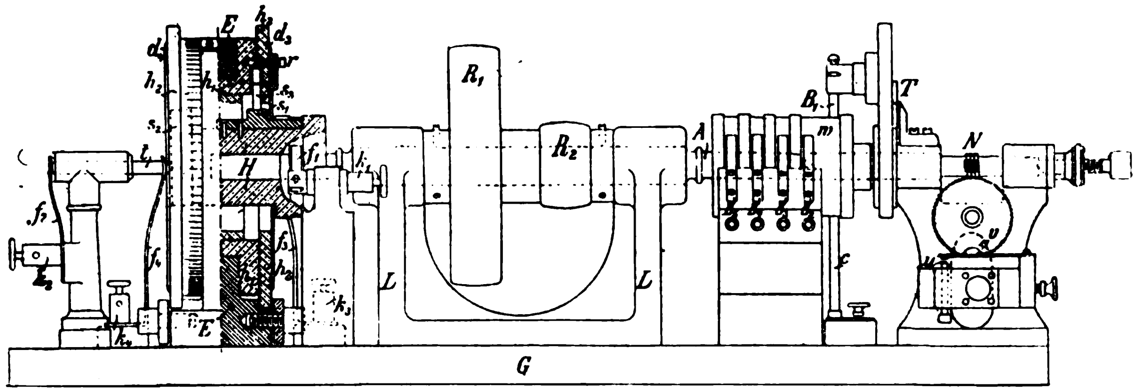

FIG. 2.—Apparatus for Reproducing and Measuring Time-current Curves.

The apparatus used in the telegraph office for the purpose above explained allows making and breaking of the circuit to be repeated at definite chosen intervals, so that a regular series of exactly equal current waves can be produced; the apparatus further renders it possible to connect either one or two points in the circuit at any desired interval in time from the instant of closing or interrupting the circuit to one or both terminals of a condenser,

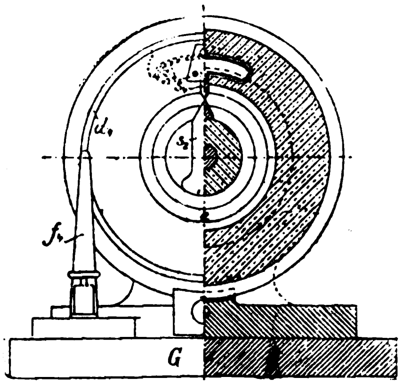

FIG. 3.

and thus to charge the latter with the potential of the one or the difference of potential between the two points. As connecting the condenser terminal to the chosen point of the circuit once only might not suffice to charge it, if the contact last only a few thousandths of a second, an arrangement is made so that the contact may be repeated in an exactly similar manner during several consecutive waves, so as to effect a complete charge of the condenser to the potential to be measured. For a condenser for this purpose an electrometer can be used and the deviation observed, or an ordinary condenser can be used, which, after being charged, can be discharged through a galvanometer.

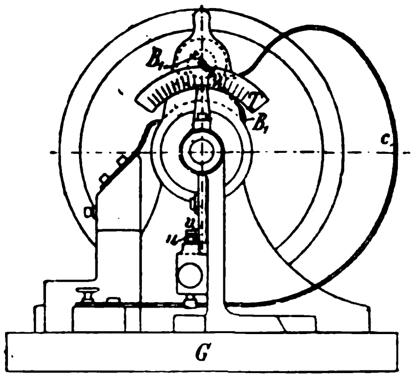

FIG. 4.

The apparatus may thus be used to form curves similar to those in Fig. 1, the ordinate (potential or potential difference) being found corresponding to any abscissa (time after closing circuit).

*Description of the Apparatus.*—In the middle of the bed-plate G (Figs. 2, 3, and 4) of planed iron is the pedestal L, which carries the steel shaft A. Between the two bearings are placed on the shaft two pulleys $R_1$ and $R_2$ of different diameters, one of which serves as a flywheel. The two ends of the shaft that project beyond the bearings are used for making the electrical connections. The left-hand end in Fig. 2 carries on a vulcanite cylinder H secured to the shaft two pointed contacts $s_1$ $s_2$. These, by means of the springs, $f_1$ and $f_2$ and the pin $t$, are connected to the binding screws $k_1$ and $k_2$. At each revolution of the shaft $s_1$ and $s_2$ make a single contact with the pointed contacts $s_3$ and $s_4$; the binding screws $k_1$ and $k_2$, as shown in diagram in Fig. 5, are connected with the two points in the circuit $p_1$ and $p_2$ between which the potential difference is to be measured. The points $s_3$ and $s_4$ are connected by means of the wires

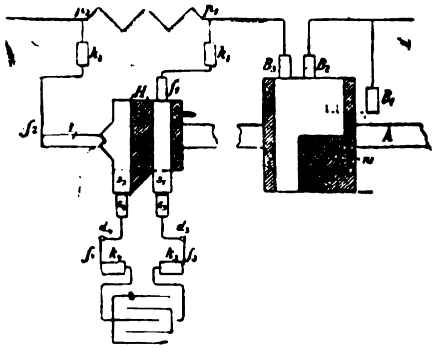

FIG. 5.—Contact Breakers

$d_3$ and $d_4$ laid in the vulcanite plate and the springs $f_3$ and $f_4$ bearing on them, with the binding screws $k_3$ and $k_4$, from which wires are carried to the terminals of the condenser or electrometer. Thus, at each revolution of the shaft, the point $p_1$ is brought into contact with one terminal and $p_2$ with the other terminal of the condenser.

Digitized by Google

The points $s_3$ and $s_4$ are attached to light springs in the vulcanite discs $h_1 h_1$ and $h_2 h_2$; the points can each turn independently on the iron ring E which carries them. The position of the points $s_3$ and $s_4$ can be read off (referred to a zero position which can be chosen) on two segments of circles, one only of which is visible in the figure. It is therefore possible by turning the vulcanite discs to set them so that the contacts between the points $s_1$ and $s_3$ and between $s_2$ and $s_4$ take place at any chosen moment, and to read off on the segments the position then occupied by the shaft. The two vulcanite discs can also be connected by a screw so that they both turn together. At $r$ are shown regulating devices by which the points $s_3$ and $s_4$ can be accurately set in position.

If the measurements are taken with the condenser and galvanometer it is sufficient to connect the point $p_2$ directly to the second terminal of the condenser.

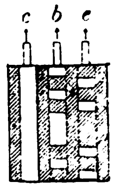

FIG. 6.—Contact Breakers to Imitate Morse Signals.
c Brush Connected with Conductor.
b " " " Battery.
e " " " Earth.

At the right-hand end of the shaft are several contact breakers. A vulcanite cylinder $w$ is placed on the shaft and furnished with several brass strips on its surface; on these slide brushes $B_1$ to $B_5$ in connection with binding screws. The first of the five brushes, which is connected to its binding screw by a long copper ribbon $c$, can be adjusted on the circumference of the vulcanite cylinder, its position being read off on the segment T. The surface of the vulcanite cylinder, with a brass strip of simple form, is shown developed in Fig. 5. A is the shaft of the apparatus; $B_1$ is the adjustable brush (shown at the side of the cylinder, its real position being indicated by the dotted lines.) $B_1$ and $B_2$ lie, during a revolution, sometimes on vulcanite, sometimes on brass. $B_3$ lies throughout on brass.

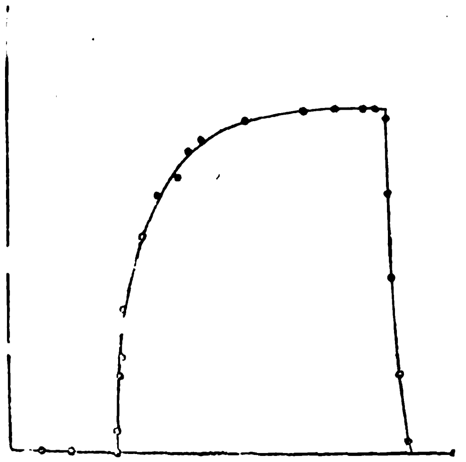

FIG. 7.—Curve Obtained from Readings given in Table.

The current will pass through the brushes $B_1$ and $B_2$ to $B_3$; so long as $B_1$ and $B_2$, or one of them, touch the brass the circuit is closed; whilst they touch ebonite it is broken. If $B_1$ and $B_2$ are placed close together, the circuit is closed through one-half and open through the other half of a turn. If $B_1$ and $B_2$ are exactly opposite the circuit is always closed, one or other of them being always on brass, so that the duration of the current can be regulated between a half and a whole revolution. If the current goes through $B_1$ and then through $B_2$ (in series) the circuit is closed so long as $B_1$ and $B_2$ are both on brass; if both brushes are together in each revolution, the circuit is closed during half of it, and if they are placed opposite the circuit is never closed, so that we can thus make the time during which the circuit is closed less than that of half a revolution.

For telegraphic researches it is useful to break the current so as to represent telegraphic signals. Fig. 6 shows the arrangement for the letter $f$ in the Morse alphabet (▬ ▬ ▬▬▬ ▬ ▬). The conductor is connected to the first brass strip, which is a complete ring, by means of a brush. The next ring shows alternately brass and ebonite; the brass portions which are in electrical conection with the brass ring form the dots and dash for an $f$. The third ring shows a form exactly the reverse of that of the second, its brass parts being also connected with the brass ring. The second ring is connected to the battery and the third to earth by their own brushes. If the second brush is on brass, the third is insulated and the current flows into the conductor; if the second brush is on ebonite, so that the battery is insulated, the third is on brass and the conductor is connected to earth. The cylinder shown therefore reproduces exactly the Morse character; the time can also be determined between the closing of the fixed contact and the opening of the working one. Similarly, cylinders can be arranged to give any other combination. As a rule, two or three only of the five brushes need be used.

At the right-hand end of the shaft is an arrangement for registering the revolutions. An endless screw, N, turns a wheel with 100 teeth. This carries a pin, $v$, which closes a contact, $u$, once during each revolution of the wheel. The number of contacts can easily be registered, or the time between two successive contacts can be taken. The speed is thus ascertained, and it can be seen whether it remains constant. To drive the apparatus one of Siemens and Halske's motors was used (K type ½ horse-power), with a cotton belt. It was found that the speeds, which ranged up to 30 or 40 revolutions per second, were quite constant.

*Results.*—After the condenser had been brought sufficiently often into contact with the points $p_1$ and $p_2$, it was cut out of circuit, and connected to the terminals of a sensitive galvanometer, and the deflection observed. This gave a value for the potential difference between $p_1$ and $p_2$, and the ordinate of the curve was determined; the abscissa is the time from the moment of contact of the brush B to that at which $p_1$ was connected to the condenser. This was read off in degrees and so obtained in fractions of the circumference.

The following is a series of readings, and Fig. 7 is the curve obtained therefrom. For plotting it, the values given in millimetres were taken for the ordinates. For the abscissæ 1mm. = ·0011 second; a complete revolution occupied ·15sec., the speed being, therefore, 400 turns per minute.

The apparatus used was manufactured by Herr H. Heele, Berlin.

## HAVOC AMONG THE POLES AND WIRES.*

If the elements continue through the year to treat the telegraph and electric overhead lines as roughly as they have during the month of January in the year of grace 1891, the companies in this section of the country will find the balances on the wrong side of their ledgers. Every Sunday thus far since the beginning of the year has been stormy, with more or less damage to telegraph and electric conductors. Last Sunday, however, was the climax, for on that day the destruction of poles and wires in New York and the region round about was even greater than during the memorable blizzard of March, 1888.

The storm began on Saturday night with rain, followed by snow and wind, and apparently concentrated all its energies against the telegraphic system of the city. The result was the almost complete

* From the *Electrical World*, New York, Jan. 31, 1891.

Digitized by Google

demoralisation of the telegraph and telephonic service. Poles and wires went down in all parts of the city like so many toy telegraph lines, and as far as one could see along entire avenues were masses of broken and prostrate poles and hopelessly tangled wires. When the storm ceased and the sun came out the sight, even where the poles were not down, was both unique and impressive. Great white hawsers had taken the places on the poles where telegraph wires had been the night before. From pole to pole, swinging low down toward the earth, these hawsers hung as thick as a man's arm. The poles themselves had grown to an enormous size, and they, too, had changed from a rusty brown to the purest white. Their cross-arms, formerly small joists painted red, were now heavy pieces of timber and all white.

The telegraph and telephone companies were the greatest sufferers, and so complete was the work of destruction that New York's sole means of communication with the rest of the country for the twenty-four hours following three o'clock Sunday morning was over three Western Union Telegraph wires—one to Albany, one to Buffalo, and another to Chicago. But these surviving wires worked so poorly that only a very limited amount of business could be transmitted over them. Every message handed in at the telegraph offices

Scene in Thirty-Ninth Street, New York, after the snow-storm of Sunday, January 25th.

was received "subject" to indefinite delay. The officials were all of one opinion, that the storm had almost beyond doubt been the most disastrous for telegraph and telephone companies ever experienced. The few reports that are in show that the storm area was large.

The American Telegraph and Telephone Company, with its highly-perfected long-distance equipment, which has stood previous storms so admirably and which furnished the only communication with Boston for two days during the great blizzard, was badly worsted by this storm. All day Sunday and late into the night efforts were being made to break the blockade and provide a channel for business before the telegraph companies recovered.

All of the land wires out of the city belonging to the Commercial Cable Company were down, and they were handling no business. The Associated Press office in the Knox building was a great sufferer. Not much more than 1,000 words were received Sunday morning, afternoon, or evening, while it is a usual thing for 15,000 words to come in at that office every night. The Western Union was not able to handle more than 2,500 words of the matter the association offered. At the office of the United Press, in the Pulitzer building, it was stated that their business was at an absolute standstill, and they were unable to furnish the hundreds of newspapers depending on them a single line of news, domestic or foreign. The Metropolitan Telegraph and Telephone Company had a tale of direful disaster to tell. As far as they were able to ascertain the whole of their uptown service was crippled. The long-distance service shared in the disaster, and it is probable that the effects of the wreck will be felt for at least two months to come.

Nor were the electric light companies much better off. The direct damage done them was considerable, but far more serious was the tangle of fallen telephone and telegraph wires that crossed their lines in every direction and made it imperative to shut down for the protection of life and property. This precaution was ordered by the Board of Electrical Control, and all night the metropolis was in darkness. As it was, the live wires were unpleasantly frequent, but beyond shocking half-a-dozen pedestrians and killing a solitary street-car horse no serious results ensued. All the companies that operate overhead wires suffered, the Mount Morris Company most severely, perhaps. The Edison system, alone, which has all its wires under ground, escaped quite unscathed. Outside the city the case was just as bad.

The damage done in Brooklyn alone, on a conservative estimate, would amount to $100,000. And elsewhere it was the same story of disaster, Jersey City, Newark, Orange, Hoboken, all suffered alike. Telephone and telegraph poles fell by dozens, wires were hopelessly tangled and crossed with electric light wires, and the electric service all about New York was simply paralysed. Altogether, the storm was the most disastrous one for many years, and while an exact estimate of the damage done will not be possible for some days, it will probably rise in New York and vicinity to not less than a million of dollars. Our sketch gives but a feeble idea of the state of the wreck at one of the points. Scenes quite as bad were to be seen all over the upper part of New York City.

## THE LONDON COUNTY COUNCIL AND TECHNICAL EDUCATION.

At the meeting of the London County Council on Tuesday, the report of the Special Committee on Technical Education (see *The Electrician*, January 23rd, p. 376) came on for discussion.

Dr. Longstaff, the chairman of the Special Committee, said he was anxious to emphasise the fact that this was by no means a unanimous report. The fundamental question was whether there really existed a need for technical instruction. Was the end desired one which individuals could accomplish by themselves? If it was an end which the individual could accomplish, it was not desirable that the municipality should accomplish it. He thought, however, that it was absolutely hopeless to suppose that any technological instruction could be given to mechanics at such a cost that they could pay for it themselves. By no conceivable means could the artisan pay the sum the teachers and apparatus required. The next great thing they must prove was that technical education was so important that it was worth their while to do it in a combined or social fashion.

Mr. Benn moved: "That the sum to be received from the beer and spirit duties on account of the current financial year (over and above the £140,000 placed to the credit of the general county account) be carried to the credit of the general county account." The position of London in this matter was, he said, quite distinct from that of any other county council, because in no other district in the kingdom were educational funds held, as they were in the City, by a clique of men occupying only one-hundredth part of the whole area. He proceeded to give particulars of what the City companies had spent on technical education since 1878, and said that the entire sum did not amount to one year's income of the companies. The total amount now devoted by the companies to technical education out of their corporate funds was not more than £35,000 per year.

Mr. C. Harrison said London stood in an exceptional position. It had the City Guilds funds of £800,000 a year, and it had the Parochial City Charities Fund, recently placed under a scheme, and dealing with £100,000 a year. Up to the date of the Act of 1889 the City Guilds granted out of the Consolidated Fund to 878 institutions in the Metropolis £14,869, and beyond that nothing was done

Mr. Cohen thought that Mr. Harrison was hardly accurate, certainly not in stating to the Council that the income of the City companies was £800,000. The spendable income of those companies was £425,000 a year. How much of the sum within their control they did spend on technical education and other beneficent works could best be judged by a few figures, which he submitted to the Council. The companies had spent alone £350,000 on the varied work of the City and Guilds Institute since 1877.

Earl Compton opposed Mr. Benn's amendment, because he believed that it was to the interests of England that London, the chief centre of commercial activity in the world, should have a proper system of technical instruction and intermediate education. That was a prime necessity if they were to compete successfully

with the other nations of the world. He looked on this £23,000 as a stepping-stone to this object.

The CHAIRMAN (Sir John Lubbock) said the Council was asked whether it was desirable that they should undertake this immense addition to their present duties. In this case, however, it was not a question whether they should undertake a new duty, but whether they should shrink from an important duty entrusted to them. They had not to consider whether it was desirable to add another to the educational authorities already existing in London. That had been decided by Parliament. They were an educational body, and the only question was whether they would fulfil or neglect their duty in this respect. As far as technical education was concerned, they were the *only* London educational body. No other public body could apply any London funds to the purpose of technical education except themselves. If the technical institutions now being formed were to receive any aid from London in its corporate capacity it must be from the representative body of London. Mr. Benn blamed the City companies. He (Sir John Lubbock) could not pretend to give a complete account of what they had done for technical education. But to the City and Guilds of London Institute they had contributed £350,000. The Goldsmiths' Company had given also £135,000 to the New-cross Institution. The Carpenters' Company maintained the Technical Institute at Stratford. The Clothworkers had given £40,000 and £4,000 a year to the Yorkshire colleges. The Draper's Company had given £50,000 and £5,000 a year to the People's Palace. The vice-chairman asked them to wait until there was an entire reorganisation of the whole government of the metropolis. Others again, because the City companies had not, in their judgment, done enough, asked them to do nothing. The £23,000 under discussion was merely the first instalment. What they had really now to consider was the principle. Many other counties throughout England had devoted this money to technical education; some of their wisest and most advanced cities had gone even further, and rated themselves for the purpose. That they were not asked to do. He sincerely trusted that London would not remain behind other counties in this respect.

The Council divided, and there voted—

| | |
|---|---|
| For the amendment ... ... ... ... ... ... | 50 |
| Against ... ... ... ... ... ... ... ... ... | 45 |
| Majority for ... ... ... ... ... ... ... ... | —5 |

Mr. BECK then moved, and Mr. BERESFORD-HOPE seconded the following amendment:—"That if in any future year any portion of the money derived from the beer and spirit duties shall be handed over to the London County Council, the whole sum so received should be appropriated to the advancement of technical education." This was negatived, and the further consideration of the question was adjourned.

## AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January* 30, 1891.

**Electric Traction in New York.**—Mayor Grant has apparently executed a change of front, the result of his trip to Boston to study the operation of the trolley system in that city. A franchise has been granted to one of the New York railway companies permitting it to string overhead wires on the upper part of Manhattan Island for the purpose of operating its cars. This step has aroused a storm of opposition, ostensibly coming from an outraged public, but probably emanating from a few newspaper offices, abetted by storage battery interests. Whatever the cause, the press has made a furious onslaught upon the permit just granted. Nevertheless, it is likely the road will be built, and the public will be only too glad to ride upon it after its completion. The electric roads at Boston have had a curious effect on property lying along their lines. The outlying districts have been greatly benefited in every way, and real estate has risen in value. In the central suburban district, however, the reverse has been the case, for the reason that the localities, which in the days of horse cars were at the extreme available limit for a residence district, now fall so far within it that the growth is largely outside of them. This, of course, is not pleasant to the property holders who are affected by this movement, and it is the protestations of this comparatively small part of the community that have been raised so loudly against the overhead system. They would be equally violent in denouncing any other form of rapid transit that enabled the less wealthy portion of the populace to build up new suburbs beyond the present ones.

**The Westinghouse Company.**—The Westinghouse Electric Company appears to be gradually emerging from the financial difficulties in which it has fallen, and there is every prospect of a speedy solution of all its difficulties. Mr. Westinghouse has been untiring in his efforts to sustain the Company through this critical period, and has met a remarkable degree of success in his work. The Stock of the Company has partially recovered from the extreme low water mark it reached a couple of weeks ago, and the outlook is decidedly brighter in every way.

**Edison Thomson-Houston Electric Traction Motors.**—The Edison Company is preparing to bring out some novelties in the way of street railway motors. One of these is a motor truck driven by two motors of comparatively low speed, each one wound for 250 volts and operated in series. Another is a device more especially the result of Mr. Edison's investigations, and contemplates the use of a single large four-pole motor, driving the car axle by means of a steel linked belt of peculiar construction. The Thomson-Houston Company is also making some modifications in its motor equipments, and experiments are being carried on by the closed conduit system patented recently by Mr. Vandepoele.

## PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *February* 10, 1890.

A new form of single fluid battery was shown at the last meeting of the *Société Internationale des Electriciens* by M. de Meritens. The negative electrode is of zinc; the positive electrode is a carbon plate, covered on the surface opposite the zinc with a thin sheet of platinised lead, the carbon itself being pierced with numerous holes. The electrolyte is a 10 per cent. solution of sulphuric acid, and the working E.M.F. is ·8 volt. The chief point of interest in connection with this cell is the fact that when the circuit is closed a torrent of hydrogen bubbles rises up through the holes in the carbon, but there is absolutely no liberation of gas on the platinised lead itself. Polarisation effects are, therefore, reduced to a minimum. M. de Meritens also described to the meeting a scheme for electrolysing sulphate of zinc with iron electrodes and obtaining pure zinc and sulphate of iron. The zinc he proposes to employ in his primary battery, the sulphate of iron being an article of commerce. The combination of these two ideas have sufficed to cause the Parisian daily Press to announce the approaching substitution of de Meritens cells for dynamos in all the Paris central stations. Tests of this cell will shortly be carried out at the Ecole Municipale de Physique et de Chimie Industrielles, so that we may soon expect to ascertain the exact value of M. de Meritens much trumpeted invention.

Since the transfer of the telephones to the State there has been a remarkable extension of inter-urban telephony. The Paris-Nantes trunk wire, 225 miles long, is expected shortly to come into operation, the charge for a conversation of three minutes being 2fr., and a line connecting Paris and Bordeaux, a distance of 325 miles, will probably be finished by the end of the present year. The group of towns forming the centre of the southern wine district, Cette, Narbonne, Montpelier, and Nimes, will also be placed in telephonic communication with one another, although the local authorities are not showing themselves very eager to make the temporary advances in support of the scheme which Government regulations demand. Rouen, which forms the centre from which radiate trunk wires, to Havre, Dieppe, Elbœuf, and Louviers, is also to have a Paris wire, so that the capital will soon be able to speak with the first port of France, over 100 miles distant.

The electric meters sent into compete for the Municipal prize are now being tested by the committee of experts, and it is hoped that the award will soon be announced.

## CORRESPONDENCE.

### ELECTRIC AND MAGNETIC THEORIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I do not know whether it is my fault that Mr. R. S. Cole, p. 433, misses some of my points and gives me others I have not tried for. I endeavour to speak plainly. My "sweeping condemnation" is confined to one thing, viz., the making of assumptions without proof, and pretending that a hypothesis is an explanation; the instances may be manifold, that is a detail, it is still only one thing I condemn.

Digitized by Google

Mr. Cole gives a *resumé* of certain hypothetical growths: it is clear and interesting, but what I ask for is *proofs.* That facts are covered by a hypothesis amounts to nothing, because it is invented for the purpose; that it covers other then unknown facts, or even leads to their prediction, amounts to nothing. The later facts may be really consequences not of the hypothesis, but of the earlier facts; also, there is nothing to prevent several other explanations equally fitting the facts, so that this mere fitting of facts is no real evidence. Mr. Cole says this himself at the end of paragraph 2, but misses seeing that it justifies my objection to the etherial electric theories as being mere and needless hypotheses.

Paragraph 3 scarcely meets my point. My objection, which applies to all the etherial notions, is that we know absolutely nothing about the ether; therefore, no one is justified in applying to it the dynamical laws and the mathematical formulæ, which are wholly based on the properties of matter, while we are positively sure that it does not possess those properties. We have every reason to believe that if ether exists, it has its own specific properties and its own laws, as yet unsuspected; that if ever discovered these will need modes of analysis utterly different from those which apply to matter; and that till discovered the true philosophy is to say that the ether transmits light across space, but that we know absolutely nothing about the process, and that any pretended explanation is mere make-believe knowledge and "science falsely so called."

As to the existence of electric waves, and the consequences deduced from the experiments of Hertz, what I say is that they do not prove the existence of the ether, which Mr. Cole substantially agrees with. The fact is self evident that the impulses of electric induction, being periodic intentionally, and being of necessity of the nature of gradual increase and diminution, must be undulatory actions; and that Hertz's experiments are purely very interesting processes for examining the well-known effects of electric induction, first discovered by Faraday and Henry, well shown years ago by Willoughby Smith, and attributed to etheric force by Edison and Batchelor a little too soon, because before the phenomena of intermittent currents had drawn eager attention to the subject, and a certain school of philosophers had taken up the ether as a convenient explanation of anything they could not understand, and put into a formula.

As to the discussion itself, I propose, at the Editor's suggestion, to put my views into the form of some articles on the electric current and its laws.—Yours, &c.,

JOHN T. SPRAGUE.

---

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Pressure of engagements has delayed me in replying to Mr. Sprague's invigorating answer to my expostulations, and I shall be too late for this week's issue.

I am glad to see that on one matter the difference between us is resolving itself into one of mere interpretation of terms. I had asked Mr. Sprague whether he was prepared to maintain that Ohm's law, pure and simple, is applicable to alternating currents, and to currents in the variable period. He replies "Yes," and then proceeds to set up a nice distinction by saying that he separates the law itself from the formulæ by which it is expressed. And, if I rightly understand what follows in this transcendental distinction, he admits that the law has to be adapted to these cases by the introduction into the formula of "a variable function." By this term I think he must mean a factor, or coefficient, of which the value is not constant, but varies with the time. If so, I entirely agree with him, because such a factor is quite necessary in any formula that is to be true to the facts. For example, the facts about an alternating current are that the alternations of the current lag behind those of the electromotive force, and are diminished in amplitude (as compared with what they would be if they obeyed Ohm's law *pure* and *simple*), in a way that depends on the amount of lag. Of course it is possible, when the circumstances of the case are known, to frame the appropriate factors which take into account the time-lag and the diminution of amplitude depending on that lag. Having done this, we can insert them into Ohm's law, which is, therefore, no longer Ohm's law pure and simple. *Ohm's law pure and simple has no time-factors in it.* Whether we ought to call it Ohm's law when we have altered it by putting time-factors into it is the verbal question upon which Mr. Sprague and I differ.

Now I come to another matter, which is more serious, not being a question of terms but of facts. Mr. Sprague has set himself to champion, and that in the most solid and consistent way, the doctrine of the longitudinal transference of energy. All honour to him for this plainness of speech. Desiring to emulate him, and to be equally consistent in maintaining the doctrine of lateral transfer, I beg him kindly to help me to frame some definite statement of the point at issue. Let us first be quite sure that we understand each other's use of language. I will begin by asking him whether he assents to the following statements, and, if not, how he would propose to amend them:—

(1) When a lamp is being worked from a battery or a dynamo, the energy which is furnished by the chemical action in the battery, or by the mechanical action of the dynamo, is transferred, in some way or other, from the source to the place where the work is done at the lamp.

(2) The energy so received by the lamp is transformed, at least in part, into heat and light (which are themselves other forms of energy).

(3) When a conducting wire is heated by the passage of an electric current through it, the energy which it receives electrically, in some way or other, from the source is dissipated in the form of heat, which escapes by radiation, convection, or conduction.

(4) When an electric current is generated (or "induced") in a circuit separated by an insulating medium from a moving magnet, there is a transfer of energy, in some way or other, through the medium, from the magnet to the circuit.

(5) When an electric current is generated (or "induced") in a secondary circuit, separated by an insulating medium from a primary circuit in which a current is varying, there is a transfer of energy, in some way or other, through the medium, from the primary circuit to the secondary circuit.

I have tried to state these propositions in language that we can both adopt; but am quite open to suggestions as to phraseology from Mr. Sprague. In Nos. (1) (3) (4) and (5) I have purposely put in the words "in some way or other" to cover the question on which we differ. If we can agree to some statement that thus covers the matter at issue we shall be the better able to state clearly, fairly, and consistently our views, and argue them. Let us do so with the common hope that neither of us may gain any momentary advantage from any slip or indistinctness in the other's words; but that whichever view as to the transfer of energy is the true one, and better represents the facts than the other, that view may come out into clear relief as being the truer view.

Mr. Sprague says at the bottom of page 406:—"The point in debate is the longitudinal transfer of energy." I quite agree that that is the point. He is prepared to argue that the energy is transmitted longitudinally along the conductor "from the source to the work." I am prepared to argue that it is transmitted in another way, not longitudinally along the conductor. I think we understand that clearly. If we don't, then let us come to an understanding before another word is spoken. I do not like that Mr. Sprague should say (as he does on page 406) that I have shifted my ground. I am trying to make sure that we are on common ground from which neither of us can shift, and I do not admit having shifted one iota from the position which Mr. Sprague has assailed.

Since writing the preceding paragraphs your issue of the 6th has brought me Mr. Sprague's second letter on page 434. I am glad to find that he too wishes to arrive at an understanding of the meaning of terms. I agree with him in applying the term ether to a "hypothetical substance," "probably existent," and probably should not quarrel much with anything he says about it on page 434, except with his assumption that it can take no structure. But all this is not really to the point and only tends to confuse the issue. I shall be quite content to do for the present without using the word ether; and will not ask for any less dense medium than common air. We shall then be spared any ulterior disagreements as to what might be the

Digitized by Google

case if the space occupied by the air were empty. The question at issue, whether the energy that goes from "the source" to "the work" is conveyed longitudinally by the copper, or is not so conveyed, can be argued without complicating the matter with the ether puzzle. One thing at a time will suffice, so it be well and honestly done.—Yours, &c.,

February 7, 1891. SILVANUS P. THOMPSON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There is one point in Mr. Sprague's letter on the above subject in your last issue to which I would beg permission to call attention. It is his statement that the ether "can possess no momentum." This assertion is made without any indication of the grounds on which it rests. I can only surmise that it is looked upon by the writer as a necessary consequence of the ether not gravitating. If this be the case, then Mr. Sprague's argument can be summed up in the following words :—"What has no gravitation can have no inertia; what has no inertia can have no momentum; what has no momentum cannot be made the subject of mechanical reasoning. Therefore ether cannot be made the subject of mechanical reasoning. But the proof that ether exists is based on mechanical reasoning, therefore the proof is invalid." If the preceding be a correct summary of Mr. Sprague's argument, I fear it will not be generally accepted as sound reasoning.—Yours, &c.,

GAVIN J. BURNS, B.Sc.

## THE INDUCTION COIL AND DR. CALLAN, OF MAYNOOTH COLLEGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am glad to see that Dr. Fleming, in his valuable Papers on the induction coil, brings out the fact, generally overlooked by other writers, and probably unknown to most of them, that the first induction coil was made by Dr. Callan, formerly Professor of Natural Philosophy in Maynooth College. It may be interesting to Dr. Fleming to know that at the meeting of the British Association in Dublin, in 1857, Dr. Callan read a Paper giving a short account of this invention, and of his own share in its subsequent development. This Paper he afterwards published, in a somewhat expanded form, in the *Philosophical Magazine* for November of the same year.

I may add that for some years before his death, which occurred in January, 1864, he devoted much of his time to the construction of an induction coil of colossal size, made entirely after his own ideas and embodying all his latest inventions. Though left unfinished at the time of his death, this coil was quite capable of being worked, and it remained, so far as I know, by far the most powerful apparatus of its kind in the world, down to the construction of Mr. Spottiswoode's great coil, about the year 1878. It is still preserved in Maynooth College as one of the most cherished treasures of the Physical Laboratory.—Yours, &c., GERALD MOLLOY.

Catholic University of Ireland, Feb. 9, 1891.

## RESISTANCE COILS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to the claims of priority now being advanced for the single wire method of winding resistance coils, will you allow me to state that in the early months of the year 1878 I made, and have still in use, a Wheatstone bridge, cable pattern, the coils of which were wound in the way described? The only advantages then anticipated were better insulation and greater convenience in winding, the coils in the absence of a lathe being wound with a hand winch.—Yours, &c., EDWARD W. ADAMSON.

Beachy Head Relay Station, Eastdean,
Eastbourne, Feb. 9, 1891.

## "MORE BOARD OF TRADE RULES."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Under the above heading you make a remark in your issue of the 6th inst. which I am somewhat at a loss to grasp, and though an explanation presents itself, it is one which, considering the tone of your leader, may hardly be that intended by the writer on the subject. Your words, "Little is known about inspection beyond the ridiculous salaries offered in London and Liverpool," are, to say the least of it, surprising, for the marketable value of a commodity usually fixes the price to be paid for the same, and it is but natural that where labour is in question the same principle should hold. Now, I have good means of knowing how and by what method the salary paid, or rather at the time *to be paid*, to the Electric Inspector of Liverpool was fixed, and, considering the exact and careful attention bestowed upon that question, upon the next, *i.e.*, the candidate to be appointed to the first inspector ship under the E.L. Acts, and lastly, as to the methods, facilities and powers to be vested in the office afterwards, it is rather amusing than otherwise to read of the "ridiculous" salary. True, it may be smaller than is paid in certain cases by commercial firms for similar value in labour and training, but a corporate body possesses such stability and affords such a field for training, together with the *entrée* of central stations and other works, that a post of this class does not lack advantages, apparent to some, which in part compensate for the scanty remuneration paid on appointment.

In London it is but natural, considering the vast area to be covered and the complexity of interests, that the operations of the officials of the London County Council should progress but "slowly," though those who take the trouble to follow their action notice the "surely" which qualifies a modest pace. In the provinces, where the ground is smaller in area and less difficult to master, and, most of all, where continuous currents have solely, as yet, to be dealt with, the work of electric inspectors necessarily proceeds apace, and as supply companies recognise the use and protection afforded by these officials they will, and perhaps even now are, be regarded less as a "necessary evil" than as a wholesome restraint upon the underlings actually employed in supply and in erection, and whose deeds so often fail to reach the chief of the works.

Little may be known in certain quarters of the work of officials already appointed, but that is rather for want of asking than because of nullity of effect.

One last word, and, with many apologies for occupying your valuable space, I will close. Does anyone consider that an electrician with commercial knowledge and thorough technical training capable of fulfilling the duties required under the Act could be obtained for less than salaries paid in London and Liverpool?

It must also be remembered that the individual will probably be required to act as superintending engineer on any electrical work carried out by his corporation, and in all cases with exception of the metropolis, the inspection and testing of mains when being laid, and afterwards, will fall to his lot.—Yours, &c., "IN STATU PUPILLARI."

Liverpool, February 11th, 1891.

[The salary of the inspector at Liverpool is £150 per annum, and it was seriously suggested that this should be paid by the electric supply company.—ED. *E.*]

# LEGAL INTELLIGENCE

### Dickins v. The Metropolitan Electric Supply Company (Limited).

This was an application before the Master of the Rolls, Lord Justice Bowen, and Lord Justice Fry, for a new trial. The action, a full report of which appeared in *The Electrician* of November 28, 1890, was brought by Messrs. Dickins and Jones, the well-known drapers of Regent-street, against the defendants, who were supplying them with electric light, for damages for suddenly cutting off the supply and plunging their premises into darkness. Mr. Justice Stephen, before whom the case came, non-suited the plaintiffs, holding that there was no evidence of any contract to go to the jury, and that the defendants were only supplying the plaintiffs at will, and could at any moment stop the supply of light. The plaintiffs appealed.

Mr. Jelf, Q.C., and Mr. R. A. M'Call were for the appellants, and Mr. Lumley Smith, Q.C., and Mr. R. B. D. Acland for the respondent.

The Court granted the application, and ordered a new trial of the action.

The Master of the Rolls said that he thought the learned judge had taken too strict a view of the matter. The question was whether there

Digitized by Google

was any evidence which could go to the jury of any contract between the defendants and the plaintiffs for the supply of electric light. In his opinion there was such evidence, although he would not say that the jury must necessarily find that such a contract existed. There was evidence of an agreement between Pritchett and the plaintiffs which appeared to have been adopted and acted upon by the defendants when they took over Pritchett's business. The case must therefore go for a new trial.

The Lords Justices concurred.

## TRADE NOTES AND NOTICES.

*[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]*

TENDERS WANTED.—The Special Sub-Committee on Electric Lighting of the Glasgow Corporation invite tenders from any company or person who may be willing to become, for any period not exceeding 21 years, the transferees of the Corporation for the purpose of undertaking all the obligations which by their Electric Lighting Order are imposed on the Corporation with reference to the compulsory area of supply defined in the second schedule to the Order. Intending tenderers are referred to our advertisement pages for further particulars as to the conditions of contract. Copies of the Corporation Provisional Order and any further information may be had on application to Mr. J. D. Marwick, Town Clerk, and sealed tenders will be received by him on or before Saturday the 28th instant.

DISSOLUTIONS OF PARTNERSHIP.—The *Gazette* announces the dissolution of the partnership between Messrs. Luckhoff, Hungerbuhler and Co., electrical engineers, of 64, Holmesdale-road, Croydon. The business carried on under the name of James White, electrical and scientific instrument makers, 16, 18 and 20, Cambridge-street, and 209, Sauchiehall-street, Glasgow, will in future be divided, Mr. David Reid continuing the Cambridge-street business under the name of James White, and Mr. Mathew Hall carrying on the Sauchiehall-street business under his own name.

BENHAM AND FROUD'S INSTALLATION OF ELECTRIC LIGHT FITTINGS.—One of the latest additions to the many firms who now make a speciality of the construction, design and supply of artistic electric light fittings is the well-known firm of Benham and Froud, of Chandos-street, Strand. We recently paid a visit to Messrs. Benham and Froud's fine showrooms, where they have a varied assortment of those elaborate brass, copper and wrought-iron fittings which the advent of the electric light have rendered possible. The premises of Messrs. Benham and Froud are supplied with current from the mains of the Metropolitan Electric Supply Company, and by means of a plug switchboard any number of the devices can be lit up for the edification of intending purchasers. Among the many taking designs we noticed a fine electric sunburner, containing six 32 candle-power lamps, with a dome of lacquered brass and a fringe of glass prisms. Some 60 of these have been fitted at the Hotel Métropole, Brighton, where, also, some 300 neat little electric table lamps have been supplied by this firm. Incandescent lamps with plain shades, hung straight from the ceiling by the conducting wires, are certainly an economical style of fitting, but Messrs. Benham and Froud propose to render them somewhat more attractive by the addition of light artistic wrought-iron sprays twined round the twin conductors. Great care will, however, have to be taken to keep these sprays as light as possible, and to prevent them from fraying the insulated covering of the wires.

## PATENT RECORD.

### APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

January 17, 1891.

871. J. F. BENNETT and E. P. SLIDES. Sheffield. Improvements in telephone transmitters.

884. C. WELLS. London. Improved apparatus for the production of electricity.

887. THE ELECTRICAL INVENTIONS COMPANY (Limited) and A. ANDREOLI. London. Improvements in or relating to the electro chemical extraction of gold, silver, and other precious metals from their ores.

889. WOODHOUSE AND RAWSON UNITED (Limited). London. Apparatus for manufacturing corrugated lead boxes for electric accumulators. (J. K. Steanes, Australia.)

899. H. J. EAGER and R. P. MILBURN. London. Improvement in electric cells or batteries.

908. F. A. ROSS. London. Improvements in insulators for electric wires.

910. A. M. CLARK. London. Electro-magnetic mechanism for controlling the transmission of power. (W. H. Kilbourn, United States.)

January 19, 1891.

937. E. ATKINS and E. E. ATKINS, Handsworth. Improvements to securely attach electrical wires to ceiling roses.

January 20, 1891.

965. H. H. LEIGH, London. Improved therapeutic magneto-electric machines. (J. B. Gardiner, United States.)

980. W. WALKER, M. WALKER, J. SANSOM, and A. COLE, Luton. Improved electric signals for railways.

984. R. THEILER and G. K. B. ELPHINSTONE, London. Improvements in telegraphic transmitting apparatus.

991. A. T. SNELL, London. An improved electric percussive rock drill.

1,004. Sir W. THOMSON, Glasgow. An improved indicator for electric potentials.

1,007. E. FERRARIS, London. Apparatus for separating ores and metals by the aid of electricity.

1,035. S. W. MAQUAY, London. Improvements in primary batteries.

1,049. S. Z. DE FERRANTI, London. Improvements in the manufacture of dynamo-electric machines.

1,050. S. Z. DE FERRANTI, London. Improved means for distributing electrical energy.

1,051. S. Z. DE FERRANTI, London. Improvements in electrical transformers or converters, and in their manufacture; partly applicable to the manufacture and testing of dynamo and other insulated conductor coils and armatures.

1,053. A. NOBLE and E. W. LLOYD, London. Improved method for testing the electrical firing gear of ordnance.

January 21, 1891.

1,066. G. D. BURTON and E. E. ANGELL, London. Improvements in electric blank heaters for forging machines.

1,084. W. H. JACKSON, London. Automatic throwback for electric indicators.

1,114. A. CHURCHWARD, London. Improvements in electric railways and in apparatus for the propulsion of vehicles by electricity. (A. J. Robertson, United States.)

1,118. O. IMRAY, London. Improvements in folding lamp shades for gas and electric lamps. (L. von Orth and E. Breslauer, Germany.)

1,122. A. D. RAINE, London. Improvements in or connected with incandescent electric lamps.

1,138. W. H. MUNNS, London. An improved guard for incandescent electric light globes. (J. Mino and W. D. Wastfield, United States.)

January 22, 1891.

1,173. S. W. THOMSON, Glasgow. Improvements in appliances for the transmission of electric energy.

1,176. F. M. NEWTON and T. HAWKINS, London. Improvements in brush-holders for dynamo-electric machines and electric motors.

1,200. W. H. COLSON, London. Electric contact for locks.

1,202. M. DEVRIES, London. Improvements in electric clocks.

1,250. E. ATKINS and W. ATKINS, Birmingham. Improvements in globe holders for electric and other lighting fittings.

1,251. E. ATKINS and W. ATKINS, Birmingham. Improvements in electrical switches.

1,279. E. C. WILEY, J. A. DICKEY, and N. B. AINESWORTH, London. Improvements in and relating to electric signals for railways.

January 24, 1891.

1,318. A. W. CUTLER, London. Improved means or arrangements for electric distribution.

1,329. W. H. MUNNS, London. An improved electrical heating and cooking apparatus. (C. Talmage, United States.)

1,332. W. H. MUNNS, London. An improved insulator for electric wires. (F. Miro, West Indies.)

# COMPANIES' MEETINGS & REPORTS.

## City and South London Railway Company.

The following is the report of Directors to the shareholders at the thirteenth half-yearly ordinary meeting of the Company, to be held at Winchester House, Old Broad-steet, E.C., on Tuesday, the 24th inst., at twelve o'clock:—

It is with much satisfaction that the Directors have to report that the railway has been completed, and was opened for public traffic on December 18th last. The running of experimental trains suggested the necessity for a number of minor improvements in the tunnels and working appliances, the carrying out of which caused some delay; but on November 4th the completion of the line was graciously inaugurated by H.R.H. the Prince of Wales, accompanied by H.R.H. the Duke of Clarence. This ceremony was followed by several weeks' private running of the trains, so that the staff might be fully instructed in their somewhat novel duties, and on December 18th the railway was opened to the public. Since that date a service of trains, running at intervals of about five minutes has been maintained, and although there have been a small number of occasional delays from the failure of engines and other causes, there is every reason to be satisfied with the use of electricity as a motive power, and when the various improvements suggested by experience are all carried out, it is anticipated that the line will prove one of exceptional safety and comfort, and will be worked with economy and regularity. During the short time the railway has been working, the average number of passengers carried has been about 15,000 per day, but as the weather improves, and the line is better known, this number will no doubt steadily increase. It has been found in working such a rapid service that the siding accommodation provided is insufficient, and arrangements are now in progress for the construction of additional sidings at the Stockwell terminus, which will add greatly to the facilities for working the line.

The Board of Trade have recommended the addition of a fourth engine and dynamo to the generating plant at Stockwell Depôt, and these have accordingly been ordered, and it is intended also to add two additional trains and four additional locomotives to the rolling stock. As soon as these additions are complete, it will allow of a considerable accession to the number of trains run, and the opening of the line on Sundays, if thought desirable. The accounts for the past half-year have been made out in the form previously adopted, but as the Company is now recognised as a railway the accounts in future will be rendered in the form prescribed by the General Railway Acts. As the line was only opened a few days before the close of the half year, it has not been thought necessary to create a separate revenue account for that short period.

With the view of developing the traffic on the line, a Bill has been deposited in Parliament to authorise the construction of a branch line from King William-street to the Bank, and thence under Moorgate-street, Finsbury Pavement, and the City-road to the "Angel," at Islington. It is anticipated that this line, when made, will bring upon the existing railway a large additional traffic during that period of the day when the trains are at present not well filled, and in addition to being itself a remunerative undertaking, will add greatly to the value of the present railway, as affording access to the heart of the City traffic, and a much-needed direct communication between the northern and southern suburbs of London. The calls upon 26 shares having been long in arrear, a formal resolution will be proposed confirming the forfeiture of the shares, and authorising their being dealt with.

The Directors retiring by rotation are Mr. Walter Robinson and Mr. Sampson Hanbury, who are eligible for re-election. The auditors also retire, but offer themselves for re-election.

The extraordinary or special general meeting of the shareholders, held on the 3rd inst., stands adjourned until the 24th inst., immediately after the conclusion of the business of the half-yearly meeting.

## The Cuba Submarine Telegraph Company (Limited).

The thirty-ninth ordinary general meeting was held at the Company's offices, No. 58, Old Broad-street, on February 11, 1891, under the presidency of Mr. Thomas Greenwood.

The SECRETARY (Mr. James Scott) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, the report and accounts have been in your hands for some days, and I apprehend that you have made yourselves sufficiently acquainted with them so that it will not be necessary to have them read to-day. The incidents have been few in the history of the Company during the last six months of sufficient importance to be brought under your notice to-day. We have gone on in the even tenor of our way. Our income has increased considerably—that is to say, we have had an improvement on the corresponding period of the previous year of £1,450, while our expenditure has been increased about £250. That has been mainly by an unusual outlay upon our land lines. We have, therefore, a net income more than that for the corresponding period of a year ago of about £1,200. There have been no breaks in our cables in the half-year—in those cables which we have to repair, that is; and there has, therefore, been no expenditure on repairs. This has enabled us to carry to the reserve fund a much larger sum than usual—nearly £4,500—after providing for the payment of a dividend of 8 per cent. on the ordinary shares, and carrying forward an increased balance of £700. That is a satisfactory state of affairs, without doubt, and I think that the shareholders will be pleased that we have so good an account to present to them. The new cable between Batabano and Cienfuegos has been successfully laid. Our reports are satisfactory, and when the time comes for the usual tests to be applied I have no doubt that we shall find that the cable is in perfect condition, and the balance of the purchase-money will then have to be paid. The purchase-money, so far as it has been paid, has been taken out of the reserve fund, and the remainder when paid will further reduce that fund; but still it will leave a considerable amount—certainly exceeding £70,000. The 1881 cable ceased to speak last August, but as the contractor was about to go out to lay the new cable we did not press him immediately to repair it, because he would have the vessel on the other side to do both repairs and laying at the same time. It was fortunate that the vessel was out there because our own cable, the one laid in 1875, broke last month. We could not mention it in the report more definitely, but we have now repaired that cable, and the line is in full working order. The 1881 cable is now under repair at the cost of the contractor, and we expect every day to receive intelligence from him that it is in perfect order. If so, we shall then have our duplicate lines completed from end to end—from Santiago to Cienfuegos and from Cienfuegos to Batabano. There is one other point to which I ought to make reference—namely, the action we have against the Spanish Government. Our case has been under the consideration of our lawyers there, and has been very carefully drafted. It has been translated and sent over here, and been under the consideration of the secretary and myself, and with certain alterations for their consideration has gone back to Spain. Nothing very much has been done, but we hope the case will come on immediately, and we confidently expect a judgment in our favour. I can hardly expect anything else, but still there is the glorious uncertainty of the law. When we get the intelligence we shall communicate it to our shareholders. I think I have now touched upon all the points which I need refer to; but if there is anything in the accounts or anything connected with the affairs of the Company upon which the shareholders would like to be further informed, I shall be very pleased to give them all the information in my power. I will now move:

*"That the report and accounts for the half year ended December 31st last, now submitted, be received and adopted."*

Mr. ALEXANDER F. LOW: I have much pleasure in seconding that.

Mr. DEARBERG: I do not know what the action is about against the Spanish Government. Is it that they have not carried out their agreement with the Company, or given another concession to another Company?

The CHAIRMAN: I may as well answer that question, though it is usual to reply to all the questions at once. The Spanish Government have granted a concession to our rivals, the French Company, with the object of giving them the right to lay on the north side of the island parallel lines to ours, which are on the south. We contend that that is a direct violation of the concession given to us, and we have taken action in the courts with the view of preventing that from being carried out.

Mr. W. GRIFFITH: In your short but able speech you anticipated one or two questions which I had intended to ask respecting the accounts, but you were also good enough to offer to give us any information which we might desire on the general affairs of the Company. The particular questions I wish to ask are these: I find that our local traffic is somewhat under one-third of our through traffic. What are the probabilities of the local traffic moving with the through traffic in coming years.

Digitized by Google

Can you tell whether there is any likelihood of the extension of the Halifax cable to Cuba, under the sanction of the British Government, being carried out, or whether that line is likely to remain at Bermuda, and go no further? This question seems to affect both the internal and the external trade of Cuba, and with that trade the future of our prosperity.

The CHAIRMAN : In reply to the two questions just put to the Board, we have no knowledge whatever of any variation that is likely to take place between the present relative income from the local as well as from the through traffic. There is no incident within our knowledge which is likely to make any variation in what has occurred before. As regards the cable which has been laid from Halifax to Bermuda, that is *un fait accompli*, but we have had no intimation whatever, and we have no knowledge or expectation, of that being continued to the Island of Cuba. We hope to retain our traffic except it be interfered with by the French Company, who is our great opponent, and if we can stop the concession I have referred to, we doubtless shall continue to carry the traffic which they give us. I will put the resolution to the meeting. I have read it; and those in favour of it will be good enough to hold up their hands. To the contrary. That is carried. I now propose

*" That the following dividends for the half-year be now declared upon the shares of the Company, viz., at the rate of 10 per cent. per annum, subject to income tax, on the Preference shares, and 8 per cent. per annum, free of income tax, on the ordinary shares, payable on and after to-morrow."*

Mr. NEIL BANNATYNE : I beg to second that.

The CHAIRMAN put the motion in the usual way, and having declared it carried, said: The business of the ordinary meeting is at an end, and we will now commence the business of the extraordinary meeting, the notice of which will be read by the secretary.

The SECRETARY having read the notice,

The CHAIRMAN said: We have rather a larger gathering of the shareholders to day; but even now I do not suppose that we have present more than one-fiftieth part of the general body, and it is that very fact of the small attendance of shareholders at these meetings which has very largely induced us to ask you to pass the resolution which I am about to place before you. We think that in all matters of importance the whole of the shareholders should be made acquainted with what is about to be done. If we seek to make an alteration in the Articles of Association we must give you notice; if we wish to make an alteration in our capital increasing or decreasing, we must give you notice; if a Director retires and offers himself for re-election we give you notice; and we think that if there is any proposal to fill up any vacancy on the Direction the shareholders should have notice of it. In order that that may be done it is essential that the candidate should give the Directors notice in sufficient time to enable them to inform the shareholders in the report. In the resolution which we propose for your adoption to-day we have put in 21 days, but we shall be ready to reduce that time if you think it desirable. All that we want is that the shareholders should be made acquainted, through the Board, of any change it is desired to make on the Direction. You are probably aware that we have not our full complement of Directors now. We have four Directors while we may have nine. Four is quite sufficient. To increase the number would not benefit the Company the least, while it must necessarily put on the Company the expense of the additional fees which would have to be paid. We do not propose, and never have proposed, to increase the number; and I think that the shareholders generally, if being satisfied with the mode in which the business has been conducted, will be content with four Directors. Still, it is open to any shareholder here, or at any future meeting, unless you pass this resolution which I am about to submit, to propose any gentleman, and, without notice to absent shareholders, fill up a vacancy which we might think ought to remain open. This resolution, as far as my knowledge is concerned, is an ordinary one, and it would probably have been put in the Articles of Association when they were drawn up had the matter been understood. Our Articles of Association were drawn up 20 years ago, and that goes for something in explaining the omission of this clause. Everyone who draws up Articles of Association has a knowledge of antecedent experience, and draws them accordingly. I will now move the proposed alteration in the following resolution :—

*" That the Articles of Association of the Company be altered by the addition of the following Article, and the same is hereby adopted as one of the Regulations of the Company :—*

*" ' No person, not being a retiring Director, shall be eligible for election to the office of Director at any general meeting, unless he or some other member intending to propose him has, at least twenty one clear days before the meeting, left at the offices of the Company a notice in writing under his hand, signifying his candidature for the office, or the intention of such member to propose him.' "*

Mr. LOW : I beg to second that.

Two amendments were successively put to the meeting by Mr. Cochran, but lost, and the original resolution (modified, as regards notice, to 14 clear days) was subsequently carried.

Mr. COCHRANE : I have been rather opposing the Directors, but I should always oppose them if I thought they were bringing forward anything against our interests. I do not, however, think that we should separate without passing a vote of thanks to the Chairman and the Directors.

Mr. GRIFFITH : I have much pleasure in seconding this motion. The resolution has been thrashed out thoroughly; everyone has had an opportunity of saying what he thought on the matter, and the discussion has been conducted with the greatest courtesy on both sides.

The resolution was carried unanimously.

The CHAIRMAN : We thank you very cordially for the handsome way in which you have acknowledged our services.

The proceedings then terminated.

## Hastings and St. Leonards-on-Sea Electric Light Company (Limited).

The annual meeting of this Company was held last week at the Works, Mr. H. M. Baker presiding.

The Directors' report stated that the accounts for the nine months ending December 31st were of a very satisfactory character. After paying all working expenses and charging to the revenue account all additions to plant and paying interest on mortgage and Debentures there remained a net profit of £543. 13s. 5d., out of which it was proposed to pay a dividend at the rate of 5 per cent. per annum, leaving a balance of £286. The Directors hoped that the time had now arrived when their services should receive some remuneration.

In moving the adoption of the report, and payment of the dividend, the Chairman remarked upon its satisfactory character, and said the three remaining months of the financial year were three of the best months on account of the short days. New plant was required for the incandescent lighting, and, to meet the expense, £2,000 worth of Debentures had been issued. Mr. Robert Hammond, who had already taken £500 in Debentures, as well as being one of the largest shareholders, had offered to take up £500 of the amount, and to supply extension of plant on favourable bonuses to the Company. Without any extension of the premises they would be able to supply five times their present custom, and there were several churches at the present time in treaty for the light.

The motion was agreed to; and on the proposition of the Rev. J. W. Tottenham, seconded by Mr. B. Bray, the sum of £200 was voted to the seven Directors for their services during the past eight years.

Messrs. F. A. Langham, J. Reeves, and J. Woodhams, the retiring Directors, were re-elected, and the proceedings terminated.

## India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

The following is the Directors' report for the year ending December 31, 1890, to be presented at the 27th ordinary general meeting of the shareholders, to be held at the Cannon-street Hotel, E.C., on Thursday, the 19th inst., at 12 o'clock :—

The accounts show the net profit for the past year to be £65,334. 11s. 2d. Adding £41,236. 6s. 8d. brought forward, and deducting £20,800 interim dividend paid in July, there remains a disposable balance of £85,770 17s. 10d. The Directors have added £25,000 of this balance to the reserve fund (raising it to £300,000), and recommend the distribution of a dividend of 10s. per share, free of income tax, amounting to £20,800, making, with the interim dividend, a total payment for the year of 10 per cent., and leaving £39,970. 17s. 10d. to be carried forward.

During the past year the Company has done a much larger general business than in any previous year, and a fair amount of cable work ; but keen competition and increased cost of material continue to reduce the rate of profit. The works and machinery are maintained in a thoroughly efficient state.

Mr. Bannatyne and Mr. Henderson, the Directors retiring by rotation, offer themselves for re-election. Mr. Weise is re-eligible as auditor.

## Liverpool Overhead Railway Company (Limited).

The half-yearly meeting of shareholders of this Company was held at Liverpool on Tuesday, and we take from the *Financial News* the following report :—

Sir W. B. FORWOOD (the Chairman) explained that the delay in construction had taken place mainly through non-delivery of material. Progress now, however, was fairly rapid. The line, which is to be 5½ miles in length along the dock line, is complete for one mile from its northern extremity, and foundations have been laid to the centre of the city. It was hoped the northern section would be at work by October. Electricity was proposed as the motive power, and tenders from four engineering firms were to be in by the end of the present month, being both for equipping the railway and working it. Quoting from American experience, he showed the probable enormous growth of traffic on the line, and anticipated no difficulty in paying a good dividend. Further calls of £1 per share would be made in April and July.

The report and accounts were adopted, and the retiring Directors were re-elected.

The CHAIRMAN, replying to a vote of thanks, expressed the opinion that in not many years the Overhead Railway would be looked upon as the best railway property in Lancashire.

## NEW COMPANIES REGISTERED.

**SHROPSHIRE ELECTRIC LIGHT AND POWER COMPANY (LIMITED).**—Registered by Chester and Co., 35, Bedford-row, with a capital of £25,000 in £10 shares. Object : To carry on the business of an electric light and power company. Registered Office, 9, the Square, Shrewsbury.

**TEWKESBURY AGRICULTURAL AND GENERAL ENGINEERING COMPANY (LIMITED).**—Registered by Jordan and Sons, 120, Chancery-lane, W.C., with a capital of £10,000 in £10 shares. Object: To acquire the business of James Savory of 103 and 104, High-street, Tewkesbury, and to carry on generally the business of engineers, machinists, ironfounders, &c.

## CITY NOTES, &c.

**BELL'S ASBESTOS COMPANY (LIMITED).**—A final dividend of 5 per cent., making 15 per cent. for the past year, is recommended by the Directors.

**BRAZILIAN SUBMARINE TELEGRAPH COMPANY.**—The traffic receipts of this Company for the week ended February 6th amounted to £5,956.

**CITY AND SOUTH LONDON RAILWAY COMPANY.**—The traffic receipts of this Company for the week ended February 7th amounted to £702. Aggregate receipts for half-year to date, £4,038.

**CITY OF LONDON ELECTRIC LIGHTING (PIONEER) COMPANY (LIMITED).** On Friday last the prospectus was issued of this Company, inviting subscriptions for a present issue of 1,000 shares of £50 each, being half the full capital of £100,000. The Company is formed to initiate the supply of electricity for public and private lighting and for motive power within the City of London, and with the intention of forming a larger company, with adequate capital, to acquire various undertakings which will secure to such larger company the electric lighting of the whole of the City of London. The prospectus states that, besides lighting the public thoroughfares, the Company will have a virtual monopoly of the private lighting of the City. The Right Hon. the Lord Mayor of London is the Chairman of the Company ; Major-General C. E. Webber, C.B., is the consulting engineer ; and Mr. J. Cecil Bull, 1 and 2, Great Winchester-st, London, E.C., is the secretary. The lists were only open from 10 a.m. till 4 p.m. on Monday last. Letters of allotment and regret were posted on Wednesday.

**CUBA SUBMARINE TELEGRAPH COMPANY.**—The estimated traffic receipts of this Company for the month of January were £2,400, as compared with £3,176 in the corresponding month of last year. The decrease is owing to an interruption during the latter half of the month.

**EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY.**—The Directors of this Company have decided to pay an *ad interim* dividend for the half-year ending December 31, 1890, at the rate of 7 per cent. per annum upon the "A" shares, to be distributed in accordance with the Articles of Association. It is intended to issue the dividend warrants on the 20th inst.

**GREAT NORTHERN TELEGRAPH COMPANY (LIMITED).**—The traffic receipts of this Company for the month of January, 1891, amounted to £20,800, as compared with £19,600 in the corresponding month of last year. The receipts for the month of January, 1889, were £22,400.

**TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.**—The Directors of this Company propose paying a further dividend of 15 per cent., making 20 per cent. for the past year.

**UNITED ALKALI COMPANY (LIMITED).**—This Company, formed for the purpose of purchasing and consolidating into one undertaking some 48 chemical works and salt mines and works in the United Kingdom, issued its prospectus last week. The share capital is £6,000,000, divided into 300,000 Seven per Cent. Preference Shares of £10 each and 300,000 ordinary shares of £10 each ; and there is also £2,500,000 Five per Cent. Mortgage Debenture Stock, redeemable at £110 per cent., at the option of the Company, after 10 years, on six months' notice. Large portions of the share capital and of the Debenture stock have been taken by the vendors in lieu of purchase money or have been otherwise allotted, and the balance is now offered for public subscription, viz., £302,650 in ordinary shares of £10 each, £659,970 in Preference Shares of £10 each, and £371,930 Mortgage Debenture Stock. Sir Charles Tennant, Bart., is the honorary president, and John Brock, Esq., the Chairman of the Board of Directors ; and the secretary is Mr. Eustace Carey, with offices at Exchange-buildings, Liverpool. The lists opened on Monday last, and closed yesterday (Thursday).

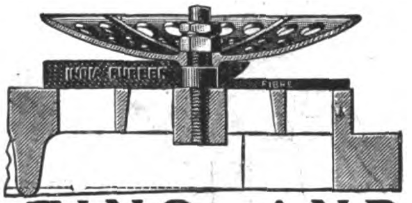
**WEST COAST OF AMERICA TELEGRAPH COMPANY.**—The traffic receipts of this Company for the month ending January 31, 1891, amounted to £3,925.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY.**—The traffic receipts of this Company for the week ending February 6, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brasilian Telegraph Company (Limited), were £4,858.

**WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).**—Notice is given that at a meeting of the Directors held on the 4th inst., a call of £1 per share was made upon the shareholders, and that the same will be payable at Messrs. Barclay, Ransom and Co's Bank, No. 54, Lombard-street, E.C., and 1, Pall Mall East, S.W., or at the Office of the Corporation, on or before the 15th day of April, 1891.

# NEW VALVE

**No Rubber, Percha, or Leather.**



**One-half the price of Rubber or Metal.**

# FOR CIRCULATING AND AIR PUMPS.

**Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.**

"12, John-street, Sunderland, 20th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

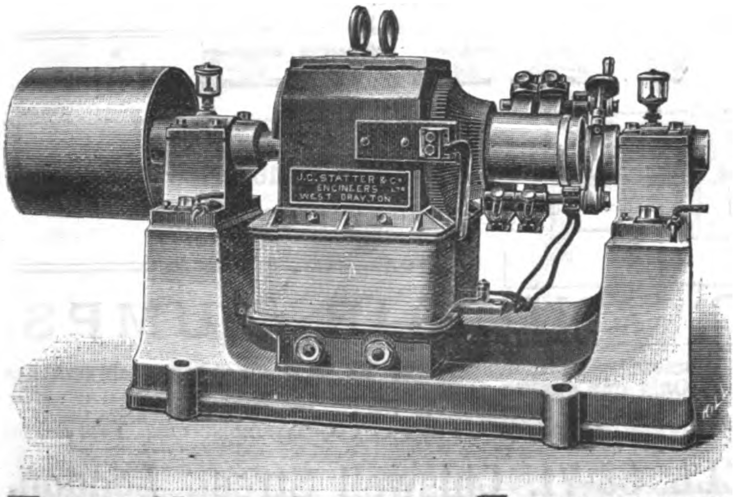
# IMPROVEMENTS IN DYNAMOS.



## STATTER-BRUNTON DYNAMO.

**The latest design in the market, made with all the advantages of the latest scientific knowledge and the highest mechanical skill.**

The woodcut represents our B TYPE DYNAMO. A most efficient machine, working noiselessly, and without sparking or overheating; is highly finished and well proportioned. The output is so rated in our Catalogue that the machines may be worked very much in excess of their stated full output for short periods.

**STOCK SIZES UP TO 77 KILOWATTS.**

**MACHINES BUILT TO 500 KILOWATTS.**

## THE ELECTRICAL ENGINEERING CORPORATION, LIMITED,

[STATTER'S] [UNITED

68, Victoria Street, London, S.W. Works:—ALLIANCE ENGINEERING WORKS, WEST DRAYTON, NEAR LONDON.

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 666.—Vol. XXVI. FRIDAY, FEBRUARY 20, 1891. Price Fourpence.

## NOTES.

On Monday last the supply was recommenced from Deptford, after having been shut down for three months. At present the current is on only between 4 p.m. and 2 a.m., as the distributing stations are not yet complete, and the engineers, who have thoroughly appreciated the facilities which the cessation of supply has afforded for carrying out the permanent work, naturally prefer to make good the constructive work without having 10,000 volts at their elbows. The present supply has shown that the London Electric Supply Corporation still exists, and their old customers are returning as fast as they can be dealt with. The first few were rather shy, each wanting to see how the other liked being connected to the new system with its enormous pressure; but finding that the lamps burned steadily at their accustomed 100 volts, the others came in freely. It is hardly necessary to state that before starting everything was tested on open circuit, the mains and transformers being subjected to 17,000 volts, and all the house connections and fuses being carefully overhauled. The overhead circuits have been entirely abandoned, and Siemens and Fowler-Waring concentric sheathed cables alone are used, the few lengths of ordinary cable previously in use have been drawn out and will be made into concentric cables. Mr. Ferranti is strongly opposed to the use of ordinary cables for anything over 200 volts, and instances the slight accident which occurred some months ago in Piccadilly, and which could not have occurred with a concentric cable.

On Wednesday last we visited the Grosvenor Gallery distributing station, and found four 150 horse-power transformers situated in a room in the basement. Two Ferranti mains, working at 10,000 volts, enter near the ceiling, and are connected with switches which allow any transformer to be put on to either main. The Cardew voltmeters were reading 105. Passing through the rooms once occupied by the machinery, and from which the boilers were being removed, a subway leads to the site of the new building. Here are established a number of switches and cut-outs on the intermediate system, distributing at 2,400 volts; and alongside this will be arranged ten 150 horse-power transformers, in two sets of five on each side, and supplied from two mains. The switches will be arranged so as to secure complete duplication. A similar set of ten transformers will be placed at Trafalgar-square, behind the P. and O. office; eight others will be laid down at Victoria Station, six at Blackfriars, besides a set at Deptford for the supply of the neighbouring district, where application has been made for some 10,000 eight-candle lamps.

The machinery actually ready for running at Deptford consists of two dynamos of 1,500 horse-power, and two of 650 horse-power. Four complete sets of mains are laid up to London, the two running to the Grosvenor Gallery being about 16 miles in length. All the sub-stations will be connected by several trunk mains, capable of conveying 2,500 horse-power at 2,400 volts. Each station will be fitted with a complete system of inter-locking switches, so that no mistake can be made. The whole group may be expected to be in working order within the next three or four months.

Most figures hitherto published in connection with that much-discussed question, the actual cost of accumulator traction, have been based upon insufficient or misleading data. The figures with regard to the first year's working of the Barking road cars, which Mr. Kapp was able to make public at the Society of Arts on Monday, are, however, of a very different character. They are the outcome of hard, practical experience, and are, moreover, given in such detail as to render them extremely valuable.

It will be doubtless within the recollection of most of our readers that, a little more than a year ago, the General Electric Power and Traction Company, after considerable preliminary experimenting, entered into a contract with the North Metropolitan Tramways Company to work the Barking-road section of their system at 4½d. per car mile by means of accumulator cars. A charging station was erected, and six cars, five of which were in constant service, were duly equipped, at a total cost of close upon £6,200. The running of these cars has been very regular, and has given satisfaction to the Tramway Company. Considerable doubt was at the time expressed in these columns and elsewhere as to the possibility of accumulator traction proving remunerative at 4½d. per car mile, and we pointed out that although the margin of profit might not indeed be very large, the meagre figures then at our disposal did not necessarily lead to the conclusion that the thing was impossible.

Mr. Kapp's figures, however, show that the cost of running 100,844 car miles per annum on the Barking-road line amounts to £3,390 4s. 4d., or 8.068d. per car mile, involving a loss

Digitized by Google

to the contractors therefore of £1,470 a year. The *total* cost of horse traction in London averages, we believe, about 10d., the haulage expenses alone amounting to 6d. Haulage by accumulators has consequently proved to be 2d. dearer than by horses. Moreover, on examining the various items which go to make up this 8·068d. per car mile, we do not exactly see where the minimum saving of 3d. necessary to render accumulator traction profitable to *contractors* is to come from. The five most formidable items are:—Wages at depôt, £677. 6s., or 1·612d. per car mile; drivers, £601. 14s. 1d., or 1·432d. per car mile; fuel, £433. 19s. 9d., or 1·033d. per car mile; batteries (depreciation and repairs), 66 per cent., £1,184, or 2·818d. per car mile; motors (depreciation and repairs), 33 per cent., £180, or ·428 per car mile. Further experience may somewhat reduce the rapid deterioration of the batteries, and when working on a larger scale wages at depôt and fuel would not contribute so markedly to the total cost; but we should be very glad to learn how it is proposed to effect any sensible reduction on these items, and whether Mr. Kapp's figures are taken from the most recent returns.

A dispute has arisen in connection with the electric lighting of Dublin, with regard to the property which an engineer has in designs submitted by him with a tender. As a matter of fact, no harm appears to have been done, since, as we reported in our last issue, the contract has been given to the Electrical Engineering Company of Ireland, in connection with the Irish House-to-House Company, and their plans have in no way been altered. But at one stage of the protracted negotiations a scheme put forward by Mr. J. E. H. Gordon somewhat fascinated the Corporation, since it was backed up by several opinions, and was endorsed by their consulting engineer. The versatility and originality of Mr. Gordon, being so well known, it was not surprising that the scheme was one that has never yet been tried in this country. Why Mr. Gordon's tender was not adopted we do not know, but we understand that it was stated that it would save £1,500 a year in working expenses, and that it was suggested to other contractors by the committee that they should amend their tenders, and adopt the chief features of this scheme.

We hoped to have placed before our readers a brief account of the new system, but we have received no information other than that large transformers were to have been used for feeding into a three-wire network, and that smaller transformers were to have been used during light loads. The idea of large transformers on a network was dealt with by Mr. Kapp in *Industries*, December 2, 1887, and was exhaustively examined by Mr. Crompton in his historical Paper on "Central Station Lighting" (*Electrician*, Vol. xx., p. 634). Numerous methods of cutting in small transformers to replace large ones have been patented, and Mr. Ferranti had a patent for the whole combination, or something very like it.

If Mr. Gordon's scheme was thoroughly protected by patents, he could, of course, have obtained an injunction to restrain the Corporation from using it, either in its entirety or in any details, but we are not aware that any other rights can be claimed. As, however, the idea of employing the scheme has been abandoned, it is unnecessary to enter into the personal questions which have arisen in connection with it. The only safeguard against such appropriation of an idea is afforded by Patent Law, but any temptation should be avoided by providing a proper specification, or if it is considered that contractors know more about the work than consulting engineers, he well-known system of competitive designs, so largely employed in architectural work might be adopted, a good premium being paid for the best designs, which might, by agreement, remain the property of the contractor as in architect's practice.

From the article we publish this week, our readers will see that Mr. Tesla has effected a further improvement in his alternating motor. The two currents, differing in phase by a quarter of a period, needed for working this motor, were at first produced by a specially wound dynamo, and needed at least three leads to conduct them. These requirements were done away with subsequently by using a transformer to produce the second current, and it is in the employment of part of the motor itself as a transformer that the novelty of the present design consists. In spite of the ingenuity of the arrangement, it does not appear hopeful from a practical point of view. The efficiency of the new motor must necessarily be less than that of the original one, since an extra transformation of energy occurs. The winding of the field magnets cannot be so effectively carried out, owing to the space occupied by the secondary coils. There will also be a large amount of waste heating, not only in the regulating resistance, but in the coils themselves, because, as in all transformers, the magnetic effects of the primary and secondary currents are opposing each other, so that it is necessary for larger currents to flow to exert the requisite magnetic influence than would otherwise be the case. The consideration of alternate current motors is very important, but alternating currents lend themselves so readily to complex arrangements whose working is of a debateable nature, that it is unfortunate that the mention of new devices is so rarely accompanied by experimental data as an aid towards a correct judgment.

Electricity already plays a sufficiently important part on a modern man-of-war, and it is destined before many more years have elapsed to greatly enlarge the sphere of its operations afloat. On land, if we may judge from Major Hippisley's Paper, which will be found in another column, the utility of the electric lightin military operations has also not been overlooked. That search lights would in future form part of the regular equipment of the defenders and assailants of first-class fortresses was to be anticipated; but portable electric light plants are, it seems, indispensable adjuncts to the defence, if not to the attack, of positions, and to the other operations of an army in the field. At present the excessive weight (4 tons) of these plants alone prevents their general introduction by the military authorities. The difficulty of hitting projectors has long been proverbial, but the experiments referred to by Major Hippisley make projectors appear so extraordinarily invulnerable that those in charge of them certainly ought to be able to secure life-policies at a lower rate than is usual.

Digitized by Google

If re-invention be any proof of the importance of a discovery, Mr. Blakesley is to be congratulated upon the number of times which his method for determining the difference in phase of two alternating currents has been independently devised by electricians. The method in question depends on the use of what Mr. Blakesley calls a "split dynamometer," the fixed and movable coils of which are traversed by the two currents under examination. The reading of this instrument is proportional to the product of the two currents, and to the cosine of the phase angle between them; so that the latter quantity can be found if the magnitude of each current is determined by any ordinary process. This method, which has been successfully applied by its author to the measurement of the power given to the primary coil of a transformer, was first published in *The Electrician* for October 2, 1885, and was afterwards reprinted in Mr. Blakesley's well-known book on Alternating Currents. It was re-invented in 1888 by Signor Ferraris, of Turin, and in the *Electrical Engineer* of New York of February 4th Mr. Chas. Steinmetz describes the same method without any reference to the work of Mr. Blakesley, and in apparent ignorance that the method is quite old. A suggestion is made at the end of the article to the effect that the method can be applied to measure the difference of phase between current and potential, or that between two electromotive forces, by using one or two fine wire coils shunted to the potentials to be tested. This suggestion is, however, of but little value, as the currents in the fine wire coils cannot be in the same phase as the potentials producing them, owing to self-induction, while the impedance of the coil, and hence the constant of the instrument, will vary with the frequency of the current.

We call the attention of our readers to the fact that the 1891 Edition of our Electrical Trades' Directory will be ready on Monday. Owing to the growth of the electrical industry the compilation of this Directory has become a task of considerable magnitude, and without the cordial assistance which is afforded on all sides the work of the compilers would be exceedingly onerous. The 1891 Directory will, we think, be found as accurate as those of previous years, and even more replete with useful information.

**The Trinidad-Demerara Cable.**—This cable is now interrupted.

**Coventry.**—At the last meeting of the Town Council it was resolved that application be made to the Board of Trade for a provisional order.

**Honour to Professor Helmholtz.**—The French Government have decorated Prof. Helmholtz with the Grand Cross of the Legion of Honour.

**Commercial Cable Company.**—The general offices in London of this Company have been removed from 29, Threadneedle-street, to 18, Bishopgate-street Within, E.C.

**Waterpower at Tivoli.**—The Italian Minister for Public Works has reported in favour of a scheme for utilising the waterfall at Tivoli and conveying the power derived therefrom to Rome.

**The Inventors of the Electric Motor.**—In the *Electrical Engineer* of New York of February 4th, Mr. Franklin Leonard Pope concludes a very interesting series of articles on "The Inventors of the Electric Motor," in which he has placed on record the work of Thomas Davenport, "the Green Mountain village blacksmith," in the field of electric motor invention.

**The New Calcutta-Bombay Telegraph Line.**—The new telegraph line from Calcutta to Bombay (1,000 miles), *viâ* the Bengal-Nagpur Railway, will be opened for traffic in the end of February.

**University College and King's College Extension Funds.**—A meeting in connection with these funds will be held at the Mansion House on Monday next at 3 p.m., under the presidency of the Lord Mayor.

**Eisenach.**—The Town Council of Eisenach has entered into arrangements with the Allgemeine Elektricitäts Gesellschaft of Berlin, for the erection of a 2,000 light central station. The estimated cost is £15,000.

**Celluloid Covered Wire.**—The Buda-Pest *Anzeiger fur die Beleuchtungs Industrie* gives an account of a new wire for electrical purposes called Hungaria wire, which is covered with two coats of thread and two coats of celluloid.

**Colliery Lighting in India.**—Charanpur Colliery, the property of Messrs. Apcar and Company, has, says *Indian Engineering*, just been lit up with the electric light. This is the first colliery in the district ever lighted by electricity.

**Electric Launches.**—The four electric launches which during the Edinburgh Exhibition season conveyed 98,000 persons along the canal between the city and the exhibition are shortly to be brought to Windermere, and will ply for hire on the lake.

**Royal Society.**—Among the Papers down for reading yesterday were—"On the Sensitiveness of the Bridge Method in its Application to Periodic Currents," by Lord Rayleigh, and "On the Focometry of Lenses and Lens-combinations," and "On a New Focometer," by Prof. Silvanus Thompson.

**Electrically Welded Shells.**—The experiments which the United States Government have for the past 18 months been conducting in connection with shell welding by electricity have resulted in the Government entering into an arrangement with the Thomson Electric Welding Company to furnish a large quantity of electrically welded shells. A new factory will be erected for the purpose, in charge of specially trained men, with every facility for producing the shells.

**The Institution of Electrical Engineers.**—The annual general meeting of the students of the Institution was held on Friday last at the offices of the Institution, when the following gentlemen were elected to serve on the Committee:—Messrs. F. A. Jones, J. H. Garret, P. Matthews, — Locke, H. B. Little, H. C. Haycroft, and A. G. Seaman, hon. sec. At the next meeting to be held on Friday, Feb. 27th, at 8 p.m., a Paper on "Electric Lighting Safety Apparatus" will be read by Mr. Stanley Bone.

**Electrical Bills in Parliament.**—Several petitions have been lodged against the Central London Railway and the extension of the Electric Railway to Islington, amongst others, by the Metropolitan Railway Company, the Dean and Chapter of St. Paul's, the Governor and Bank of England, and various persons affected on the line of route. The London County Council Overhead Wires Bill is opposed by the Honourable Societies of Lincoln's Inn, the Inner Temple, and the Middle Temple, as well as by the East London and Metropolitan District Railway Companies.

**Village Lighting.**—The local authorities of Lockstedt, near Altona, have decided to introduce a system of electric lighting in the streets. The carrying out of the installation has been entrusted to the Thomson-Houston International Electric Company of Hamburg.——The village of Fardo, on the St. Gothard line, also has a small electric light plant, driven by water-power under a head of 480ft. Current is supplied by two dynamos, each capable of giving 160 amperes at 140 volts. The village is lighted by 360 glow lamps, those in the streets being of 25 candle-power.

**Electric Lighting Legislation in Germany.**—The electric lighting and allied industries in Germany have developed so considerably during the past few years that the German Government has decided to bring them under legislative control. An Electric Lighting Bill has, therefore, been introduced into the Bundesrath. It contains 15 clauses, referring to the erection and working of central lighting stations, the distribution, and application of electricity for the purposes of light and power, underground conductors, and the working of private installations, &c.

**The Abridgement of Patent Specifications.**—In answer to Mr Leng, Sir M. Hicks-Beach stated in the House of Commons last week that the abridgement of specifications in the Patent Office had only been commenced within a comparatively recent period; but it is being now pushed forward as speedily as possible. He estimated that during the financial year ended March 31st 16,000 specifications would have been abridged, and that approximately the same rate of progress would be maintained until the arrears were overtaken. Abridgements of only three classes were out of print, and he was not aware of any large demand for a reprint of these.

**Secondary Battery Plates.**—The following process of secondary battery plate construction has lately been brought out by Mr. C. F. Brush. It consists in producing upon the grid an electro deposited active coating; then immersing the plate in an electrotype in which the coating is insoluble, and afterwards peroxidising the coating by electrical action. The spongy lead is deposited upon the grid as in any ordinary process of electro-plating, the plating solution consisting of acetate or nitrate of lead, or of sulphate of lead dissolved in any suitable neutral saline solution. The spongy metal is deposited very slowly, in order that it may have sufficient compactness to retain its position.

**Electric Lighting in Victoria.**—The *Building and Engineering Journal* of December 27, 1890, contains an illustration and description of the central lighting station of the A. U. Alcock Electric Light and Motive Power Company at Richmond (Vic.), which is now in course of erection. The building will cover an area of about 1½ acres. The station when completed will supply about 250,000 incandescent lamps, and the portion now being erected will contain machinery equal to the supply of 20,000. When completed and fitted with the necessary machinery the station will be the largest in the Southern Hemisphere, and it is estimated to cost over £250,000.

**Electrical Transmission of Power in Switzerland.**—The Oerlikon Machine Works have acquired water power at the village of Hochfelden, in the Glatt valley, sufficient for driving two turbines, each of from 200 to 300 horse-power. Electricity, says *Industries*, will be generated at Hochfelden, the pressure being 25,000 volts, and transmitted to Oerlikon, a distance of twelve miles, by means of overhead wires supported on 40ft. poles, alongside the railway and the country roads. There will be four cables, each 4mm. in diameter, of which one will serve as a reserve. At the works the pressure will be reduced to 50 volts, and the power will be utilised for driving the whole of the machine tools in the establishment.

**The Australian Cable Rates.**—The following letter from the Secretary of the Eastern Telegraph Company appeared in the *Financial News* of Thursday last week:—"Sir: In your issue of this date (February 12th), quoting from a statement in the *Melbourne Age* you state that 'the Company says it is not only unprepared to introduce the new tariff offhand, but cannot even name a date when it will be able to do so.' I am instructed to say that in the agreement which has been arrived at with the interested telegraph administrations, now before the Australian colonies, it is stated that we can reduce the tariff in 15 days after the Australian Governments have accepted the conditions. So far as we know, there is no suggestion of any disagreement up to this time."

**The Electric Lighting of the Brighton Grand Hotel.**—At the thirty-first ordinary general meeting of the Brighton Grand Hotel Company on Wednesday. The Chairman complained of the way in which the Directors had been treated by the Electric Light Company who had endeavoured to force upon them an engagement for three years, and had cut off the light after a few days' notice because they had refused to enter into it. But for their foresight in providing gas connections when electricity was put in they would have been left in darkness. However, they had now put in an electric lighting installation of their own at a cost of about £6,000, which, calculated at 5 per cent., meant £300 a year, whereas they had been paying £2,000 a year for electricity hitherto.

**New Thomson-Houston Street Railway Motor.**—During the past year the Thomson-Houston Electric Company have been experimenting with a new slow-speed motor for street railway service. The new motor is nearly iron clad, having two internal pole pieces of ample spread, carrying two field coils, which partially surround the armature core. The armature is of the Gramme ring, instead of the drum type formerly used by the company. The spur pinion on the armature shaft is of steel, 4½in. face, and has 14 teeth. The split gear, which is bolted on the car axle, is of cast iron, with the same width of face, and has 67 teeth. The speed of the armature shaft relative to that of the car axle is nearly 4·8 to 1, and when the car is running 10 miles per hour the armature makes 530 revolutions per minute.

**European Telegraph Statistics.**—In its review of the past year, the *Journal Télégraphique* gives the following figures:—According to the latest statistics, the European telegraph administrations now place 353,400 miles of line and 1,023,000 miles of wire at the disposal of the public, an increase respectively of 4·6 per cent. and 3·1 per cent. upon previous returns. The increase in the number of telegraph offices has been very marked of late. In the seventh edition of the "Nomenclature des Bureaux," which appeared in 1887, 60,000 names were given, the eighth edition contains 75,000 names, or 25 per cent. more. The number of telegrams transmitted also continues to increase. Last year 200,000,000 messages were despatched in Europe, of which 45,000,000, or 22·5 per cent., were international.

**A Century of the American Patent System.**—The *Electrical Engineer* of New York has the following remarks with regard to the proposed celebration of the forthcoming centenary of the American Patent System:—"It is proposed, and all the preliminary arrangements have now been completed for the purpose, to celebrate next April, in Washington, the completion of the first century of the American Patent System. Such an occasion as this will be a most favourable one for impressing upon the public mind the enormous benefits that the system has conferred upon American civilisation and development. If we wish to stop the present rapid rate of advance in the arts and sciences, in general welfare and individual comfort, all that is necessary is to abandon the system. The system is not perfect, far from it, but it is one of the most useful and praiseworthy of our institutions, unsurpassed as a creator of property and values and blessings common to all."

**Elliott's Smoke Annihilator.**—In the House of Commons, on Tuesday last, the First Lord of the Treasury was asked whether his attention had been drawn to Mr. Elliott's invention for the annihilation of smoke, now on view on the Thames Embankment; and whether it was the intention of the Government to give the invention a trial, with a view to the possibility of taking some steps to abate the smoke nuisance in the metropolis. Mr. W. H. Smith replied that he was not personally acquainted with the apparatus in question, but he was informed by the Metropolitan Police, whose duty it was to enforce the Acts relating to the smoke nuisance in the metropolis, that smoke had been observed to issue from the chimney on the Thames Embankment, from which it might be inferred that the apparatus was not at all times successful. Referring to this statement, Mr. Samuel Elliott says that in order conclusively to demonstrate the effectiveness of his system large quantities of smoke are generated which directly his machine is set in motion disappear.

**Electricity on the Stage.**—It is prophesied, says the *Western Electrician*, that the stage will soon become one of the most profitable fields in which the electrician may exercise his ingenuity. Mr. Neil Burgess believes that electricity will revolutionise stage management in a few years. He says that by the use of electric motors the whole mechanism of a complicated play can be put under the control of a single man, and manipulated with such facility and rapidity as to very much reduce the waits between acts, and entirely obviate any of the exasperating hitches which otherwise might sometimes occur. He proposes still further to increase the application of motors to his own stage setting, so that as far as possible all mechanical devices and movable scenery, curtains and the like, will be handled by motors from one point with great rapidity, and without the danger from careless attendants. The Universal Arc Lamp Company of New York make an arc lamp for

Digitized by Google

theatrical purposes. This is described in the *Electrical Engineer* of New York. It is provided with lenses and coloured screens, and works at 45 volts.

**Electrical Mutual Insurance.**—About a year ago the owners of central lighting stations in Massachusetts, and others, being of opinion that the existing insurance companies' premiums were unwarrantably high, formed themselves into a mutual insurance company, and a very instructive report has just been published. The company issued its first policies on May 15th. The report covers the operations to December 31, 1890—7½ months. The outstanding risks amount to $2,897,587, the premium on which is $30,320.71—an average rate of about 1⅓ per cent. The average amount of policies is $9,055. Not a dollar of loss has occurred on any station insured. The average rate prevailing previously was about 2 per cent. The report concludes as follows:—"Your Board feels that you and those engaged in electrical development generally will not fail to appreciate the good results that will follow, and the fire losses that may be avoided by, the dissemination of practical and valuable ideas pertaining to safety, through the intelligent inspection of its risks by an assurance association devoting itself especially to the electrical business."

**Gas and Electric Light Undertakings in Massachusetts.**—The following is from the sixth annual report of the Gas and Electric Light Commissioners of Massachusetts—embracing the twelvemonths ending in June last:—Although there has been a steady progress of electric lighting, there has been in most places a gradual increase in the consumption of gas. Electric motors are coming into more general use, although their cost has not been much lessened. It is suggested that the Board should have power to call on the State Gas Inspector to test the candle-power of the electric light. In twenty-four cities and towns the companies furnish both gas and electric light. During 1890 five persons were injured, three fatally, by electric light plants; and 23 persons were injured, eight fatally, by illuminating gas—two of the latter being suicides. During the year there were 12 electric light companies incorporated, with a total capital of $267,000. The electric light companies paid dividends of $153,708; but only 21 out of 60 did so. The electric light central stations showed receipts of $1,920,702, and a balance of $579,887; the gas companies receipts of $5,270,991, and a net balance of $1,608,618.

**Electrical Purification of Sewage.**—The Salford Corporation instituted an exhaustive series of experiments last year on the treatment of sewage with a view to the adoption of the most suitable system for the purification of the Salford sewage. Trials were made at the local sewage works with four methods, namely, the International, the Electrical, the Aluminoferric, and the Barry systems. The services of Mr. Carter Bell, the borough analyst, Mr. J. Newton, C.E., Dr. Burghardt, and Mr. O. Giles, of Messrs. Mather and Platt, were secured to investigate the systems and draw up a report. This has now been presented to the Corporation. The Aluminoferric and the Barry systems are considered to be less satisfactory than the International and the Electrical. Mr. Carter Bell, in summing up his report on the chemical aspects of the two latter systems, states:—"If the International or the Electrical Company will guarantee the Corporation of Salford to produce an effluent from the whole of the Salford sewage which shall equal the effluents they have produced during the last few months, then I think the Corporation will be justified in expending the large amount of money that would be involved in purifying the sewage."

**Telegraphic Communication with Hawaii.**—The United States Senate spent three hours on Monday in secret session debating the following amendment to the Diplomatic and Consular Appropriation Bill:—"In order to enable the President of the United States to enter into an engagement with any citizen or corporation of the United States, as shall appear to possess the means and facilities necessary to that end, for the establishment of telegraphic communication between the United States and the kingdom of Hawaii, which engagement shall contain provisions sufficient in the judgment of the President to secure to the Government and citizens of the United States early and equal communication by telegraph with the kingdom of Hawaii, on reasonable terms, for a period of not less than 14 years, a sum not exceeding $250,000 is hereby appropriated for each year during which the engagement shall be in operation, the term during which such engagement shall be so in course of execution not to exceed 20 years. The sum total to be paid under this authority shall not exceed $3,000,000." The amendment was agreed to at the secret session; but the actual voting upon it was reserved for the open session, when it was re-adopted by 35 to 22.

**Electric Traction at Buffalo (N.Y.).**—The various street railway companies in Buffalo (N.Y.) have recently amalgamated, and, in addition to the adoption of electric traction, considerable extensions are in progress. When the system is complete it will comprise 106 miles of track, over which 300 cars will be in daily operation. The power house will contain plant having a final aggregate capacity of 5,500 horse-power. About one-third of the line will be centre-pole construction, with tracks spread to 6ft. In order to make the line more secure, and less cumbersome in appearance, the feeders will be generally run in underground conduits. Babcock and Wilcox boilers, 250 horse-power Ball engines, and 225 horse-power Edison dynamos are being installed. All the engines have heavy fly-wheels, weighing seven tons, and running at 210 revolutions. The feed wires are connected up to the trolley wire from the underground conduit at every eight poles, or about every 1,000ft., all connections being made from man-holes. Two styles of underground tubing have been used, about one-half of each, namely, the wood pulp pipe of the Indurated Fibre Pipe Company and the cement-lined pipe of the Standard Underground Company. The best insulated lead and jute covered cables are used throughout in the conduits. All the track of the company is being reconstructed and built in the most substantial manner.

**The Electrical Standardising, Testing, and Training Institution.**—A *conversazione* was held at Faraday House, Charing Cross-road, on Monday evening last, by Mr. and Mrs. Robert Hammond, in connection with the Electrical Standardising, Testing, and Training Institution, which has recently taken up its quarters there. This Institution, which is under the management of Mr. Hugh Erat Harrison, formerly Principal of the "Hammond College," is well equipped with apparatus, and is provided with a number of laboratories, lecture rooms, workshops, &c. The work undertaken by the Electrical Standardising, Testing, and Training Institution, as its title implies, comprises the standardising and testing of electrical instruments and apparatus, the inspection of installations, the testing of inventions, and the training of electrical engineers. The course is spread over two years, one of which is devoted entirely to practical engineering work. It is the intention of the Institution to affiliate itself with some of the principal electricity supply companies, and this has already been done in respect of the London Electric Supply Corporation, the House-to-House Company, and other companies. By this means it is proposed to give students an insight into the actual working of large generating plants. The proper training of electrical engineers is undoubtedly a matter of considerable importance, and the degree of success which attends this somewhat novel Institution will be watched with interest.

**The Lieb Elastic Trolley Wheel.**—The operation of electric railways has, says the *Electrical Engineer* of New York, developed the fact that while the trolley wheel is a most simple device for taking off the current from the overhead conductor, it labours under the disadvantage of affording only a small surface contact for the passage of the current being reduced, in fact, to a mere tangent point. As a result, the resistance of the contact entails a loss of energy, and at the same time causes a decided heating of the trolley wheel, which, in consequence, requires copious lubrication to keep it in good running order. Again, the solid trolley wheel at present employed has a tendency to jump, causing sparking, as well as noise and wear. To obviate these difficulties, Mr. Lieb has designed an elastic trolley wheel. This wheel is provided with a lining of brass in which springs are cut and curved outwards away from the plane of the sheet and having their ends curved inward again. The pressure of the trolley-wire on the springs compresses them

Digitized by Google

so that there is relatively no shock or jar of the trolley against the wire, and separation of them is largely avoided; the shock of the trolley also, when it comes in contact with the clamps by which the trolley-wire is suspended, is largely avoided Thus the movement of the trolley along the trolley-wire is smooth and even, and sparking, wear on the parts, and noise are much reduced. In the usual form the trolley-wire comes in contact with only a very small arc of the trolley-wheel and at one point through which the contact must be made, in the new construction the flattening or compressing of the yielding surface of the wheel upon pressure by the wire or its attachments greatly enlarges the area of contact.

**Boiler Compositions.**—In the whole range of this country's industries, says the *Chemical Trade Journal*, we question if there is any one branch which yields such enormous profits as that of boiler composition making. Not that the price of these commodities is ruinously heavy, but rather because the cost of production is almost incredibly small. In point of fact, when once a composition has been forced on the market, the fortunate maker may charge pretty much what he pleases. . . . We still hold to the grand old maxim that "prevention is better than cure." A thousand times better keep lime salts out of one's boiler than proceed to cure their effects once they have got in. We are well aware that this is a difficult thing to do, but it can be done if people will only go to the trouble and bear the first cost of the necessary plant, which would in a large number of cases save many hundreds of pounds sterling every year by the abolition from one's works of these delusive boiler compositions, which, in the long run, constitute about the most expensive method of boiler cleaning that could well be devised. We admit that in some cases the proper cleaning of feed-water before it enters the boiler is impracticable, owing to want of accommodation, boiler-power not large enough to warrant the erection of softening plant, and other reasons, in which cases the simpler the remedies the better. Ordinary tanner's sumac cannot be beaten for this purpose, and it can be obtained in almost any part of the country at a very cheap rate. The excessive use of this substance must, however, be avoided, as it then acts slightly on the boiler plates, but with ordinary and intelligent usage one need have nothing to fear. In conclusion, we would again impress upon all steam users the advisability of having their feed-water properly softened before being used in the boilers.

**An Indicator of Acidity in Boiler Waters.**—As is well known, water containing magnesium chloride is injurious to boilers, as the salt dissociates with the production of hydrochloric acid which attacks the plates. In large installations says *Industries*, where systematic purification of the feed water can be adopted, this evil is prevented, but in most cases the treatment in vogue consists in adding caustic soda to keep the contents of the boiler alkaline. An excess of the soda is wasteful and otherwise objectionable, and it becomes desirable to be able readily to ascertain when the water in the boiler ceases to contain alkali and needs a further supply. The handiest way to do this would be to have a certain quantity of some indicator always present in the boiler, but unfortunately all the usual indicators, such as litmus and turmeric, become decolorised under the influence of water at high temperature and pressure; the same objection applies to Congo red. Dr. Goldberg has, however found that the sodium salt of paranitrophenol is entirely unaffected either by these conditions or by the salts usually present in feed waters. It is therefore possible, by introducing a sufficient quantity into the boiler, to judge of the alkalinity or acidity of its contents at any given moment by merely blowing the water out of the gauge glass and allowing it to refill. To give a distinct yellow colour (the evidence of alkalinity) to the water, so that it may be seen in the small quantity of water in the gauge glass, about 30 to 50 grammes per cubic metre are requisite. The high price of the substance is the bar to its general use at present. As its successful application is not dependent upon its purity, a crude variety could doubtless be produced much more cheaply if a demand arose for it.

**Metallic Thermometer with Electric Recording Gear.**—M. Chibout, says *Le Génie Civil*, has brought out a very sensitive metallic thermometer, constructed so that readings can be taken at a distance. It consists of a transmitter, or thermometer proper, and an electrical receiver. The transmitter consists of a bar of metal which easily expands, such as zinc in thin plates, but of such a section that it possesses the greatest rigidity possible. This bar is fixed at one end to a marble support, and at the other is joined to the short arm of a lever; to the long arm of the same lever, and at the same side of it, is fixed another similar bar, and the other extremity of the second bar acts on a similar lever, to the long arm of which is fixed a rack-gearing with a small pinion, on the axis of which is carried a pointer working over a dial, which registers in degrees the movement caused by the expansion of the two bars. Each joint between an expansion rod and a lever is made by means of a piece of spring steel, so as to avoid friction and still allow perfect play. Upon the last lever is fixed a radial contact-maker, which moves over a sector consisting of contact pieces insulated from each other. The receiver consists of a solenoid, in the centre of which is a spindle carrying a pointer travelling over a circular dial. The pointer carries at one end a small piece of soft iron, which, in the normal state, rests against another stationary piece of soft iron. Under the influence of the current, which proceeds from the distant apparatus, the two pieces of soft iron become magnetised with the same polarity and repel one another, and the needle travels through an angle proportional to the intensity of the magnetising current, so that a record is given on the receiver similar to that on the thermometer dial itself. The instrument is specially intended for allowing the temperature of distant rooms, where a constant heat must be maintained, to be read in the office. The above description is from the abstracts of Foreign Papers, published by the Institution of Civil Engineers.

**Overhead Wires as a Permanent Investment.**—The destructive storm of January 25th still continues the subject of much comment in the American technical press, and under the above heading Dr. S. Schuyler Wheeler, Electrical Expert to the New York Board of Electrical Control, makes some interesting remarks in the *Electrical Engineer* of February 4th. The collapse of the wires, he says, presents many curious and suggestive features. Some of the finest line construction in the world went by the board in an hour or two. A simple calculation will furnish the explanation. The snow as it fell and clung to the wire, fanned out beneath until each wire soon looked like a three-cornered ruler slightly rounded, the wire forming the upper edge. Each foot of that wet snow weighed about one pound. The extra weight thus suddenly thrown on was not less than 8½ tons per pole, applied at the height from the ground of 80 or 90 feet. Another striking feature was the variation in the manner of break-down. About two-thirds of the poles were broken, and about one-third were uprooted. Those uprooted were earthed only three or four feet. In all the best construction now, such as the long distance telephone line, the poles are set to a depth of 8ft. or 9ft., and in new soil even deeper. One method of construction carried out under the direction and approval of the Board of Electrical Control, pending the completion of the subways, came through the ordeal successfully. Hitherto it has been the practice to place the electric light wires bottom of all, although they are the strongest and least liable to break. On First Avenue, the electric light circuits of the Manhattan Company have been put away up above everything, at a height of 80ft. That pole line stood without a scratch. The Metropolitan Telephone Company, upon whom the heaviest blow fell—3,897 subscribers being disconnected—are more than confirmed by the storm in their intention to get every wire underground as quickly as possible. Even where the incompleteness of the subway system might allow them to rebuild, they will not attempt it, feeling that the permanence of the old overhead system is not great enough. The exhibition of destructive power made by a quiet little snow-storm that lasted barely nine hours ought to suggest, in interested quarters throughout the country, some weighty reflections on overhead lines as a permanent investment where a large number of circuits are to be run together, and to point the moral that, imperfect as subway systems and methods may yet be, they alone answer the requirements of the situation, and are equal to the emergency in a great city.

## THE MAGNETIC CIRCUIT OF TRANSFORMERS: CLOSED VERSUS OPEN.

BY S. EVERSHED.

(1) The alternate current transformer has led a curious dual existence since its appearance in this country, some ten years ago. Not having had the advantage of English parentage, it was necessarily regarded somewhat askance, especially as claims were made for it amounting to thinly veiled perpetual motion. However, when it occurred to someone to use transformers in parallel we quickly adopted it, and since that time it has been a mainstay in all lighting schemes covering large areas. Having adopted it as one of our own children, the first thing to be done was to provide it with a complete suit of mathematical clothing; accordingly Prof. George Forbes supplied his "Formulæ for Converters," Mr. Kapp settled the proportions of iron and copper, and nothing remained to be done. Practical men for the most part took no notice of these more or less mathematical essays, or, if they did, declared the clothing to be a misfit; while the mathematicians urged that the transformer ought to be squeezed into the garments provided for it at any cost. Future students of the history of the transformer at this time will probably recognise two entirely distinct types: the ideal or phantom transformer, and the transformer which runs lamps; the phantom being chiefly remarkable for the number of its constant co-efficients and for its usually immaculate iron core, while the transformer engaged in actual work, haply unconscious of L and M, could not keep its iron cold, and showed a distinct tendency to weakness in insulation. In short, the phantom and the real have developed side by side without any clearly apparent relation between theory and practice as cause and effect.

(2) Quite recently an interesting volume has appeared from the pen of Dr. Fleming, in which simple harmonic currents are largely dealt with, and several steps are taken to reconcile the phantom with the real by admitting that there are not one but three sorts of self-induction coefficient, mostly variable, besides a variable coefficient of mutual induction. This is indeed a welcome advance, and goes some way towards the final abandonment of such coefficients altogether in this connection. Matters being in this condition Mr. Swinburne, who already had a considerable reputation as a maker of paradoxes, electrified the B. A. meeting of 1889 by telling section G that the closed magnetic circuit was a mistake, and that for his part he intended to make open circuit transformers, they being both cheaper and more efficient under all usual conditions as to load. No one being inclined to discuss such a revolutionary proposition, Mr. Swinburne retired to Teddington to prepare "Hedgehogs" and more paradoxes. But he left behind him an uncomfortable suspicion that the "all-day efficiency" of most real transformers was lamentably low, and it cannot be supposed that the matter will be allowed to rest. In fact, the financial success of every alternate current supply company depends, to a large extent, on the all-day efficiency of its converters, so that it is of vital consequence to them to know what design to adopt for any given condition of load. It may be said at once that the problem of determining the best design for a given load is too complex to admit of ready solution, and the writer cannot hope to do more in the present articles than clear the ground by discussing the relative merits of closed and open transformers considered as part of a distribution system.

(3) The waste of energy in the transformers themselves being the key to the whole problem, we will first determine the amount of the various losses which go to make up the daily waste. The only losses of any practical importance are those caused by (1) Hysteresis in the core, (2) Eddy currents in the core, (3) Eddy currents in the coils, and (4) $C^2R$ loss in the coils. Of these the first two are now generally admitted to be the most serious. Having discussed the question of waste in the case of one or two closed and open transformers, quite apart from any consideration as to phases of induction, current and E.M.F., we shall next describe a method by which the periodic curves of these quantities may be drawn so as to give a true diagram of what is going on in a transformer under varied conditions of load.

The mathematical reader will do well to abandon the writer at this point, as in all probability L, M, and other such attributes of the phantom will not be mentioned.

(4) As an illustration of the method adopted in calculating the waste, we will take a 30 horse-power Goolden-Ravenshaw closed transformer, and determine the losses in it at full load. The writer has no reason to suppose this particular type to be either better or worse than others of its class; he simply takes it as an example because, in addition to the dimensions and other data, given in Table I., he has in his possession several cyclic **B-H** curves taken from specimens of the iron from which the cores of these transformers are made.

**Table I.**—*Thirty horse-power Closed Transformer.*

| | | | |
|---|---|---|---|
| Full load output ........................ | = | 22·4 | kilowatts. |
| Frequency = F ........................ | = | 70 | per second. |
| Total volume of iron in core ...... | = | 13,700 | cc. |
| Sectional area of iron in core ...... | = | 95 | sq. cms. |
| Mean length of magnetic circuit.. | = | 145 | cms. |
| Width of core plates = $b$ .......... | = | 15·2 | cms. |
| Thickness of core plates = $t$......... | = | ·05 | cm. |

| — | Primary. | Secondary. |
|---|---|---|
| Volts........................................ | 2,000 | 100 |
| Turns on coil .............................. | 680 | 34 |
| Resistance .................................. | ·97$\omega$ | ·003$\omega$ |

*Hysteresis Loss.*—This is found from the area of the **B-H** curve, taken between the maximum **B** on each side of zero, and

$$\text{maximum } \mathbf{B} = \frac{9\,\text{E}.10^8}{10.4\,\text{N A F}} \quad . \quad . \quad . \quad . \quad (1)$$

here, and throughout these articles E is *effective* E.M.F. in volts; so also C will always stand for *effective* current in amperes.

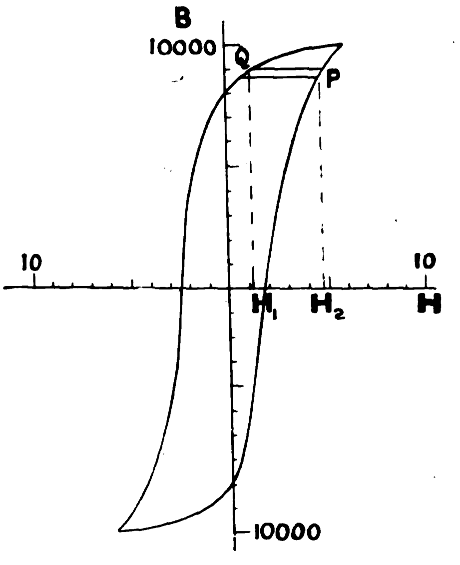

FIG. 1.—**B H** Curve taken from Charcoal Iron used in Ravenshaw Transformer.

E and N may be either the primary or secondary E.M.F. and turns; preferably the latter, the secondary being nearest the core. To reduce E to average E.M.F. we have used the coefficient $\frac{9}{10}$.

Putting the values given in the table into (1) we find maximum **B** = 10,000 gausses. The cyclic **B-H** curve between + and − 10,000 gausses is given in Fig. 1. Its area, measured by a planimeter, is 81,600 gauss-dynes, which, divided by the ubiquitous $4\pi$ gives the loss in ergs per cubic centimetre per cycle.

Digitized by Google

(5) An elementary proof of this well-known relation between the area of a cyclic **B-H** curve and the loss of energy may not be amiss. Suppose such a cyclic curve as that shown in Fig. 1 to be taken from a ring of iron one square centimetre in sectional area, and $l$ cms. in mean length. Let the magnetising coil have N turns, so that

$$\mathbf{H} = \frac{4\pi N C}{10\, l}$$

where C stands for current in amperes, take any point, P, on the rising curve, and consider what happens when **B** increases by a small amount $\delta \mathbf{B}$ during a short time $\delta t$; **H** has the value $\mathbf{H}_2$ during this change. What is the work done by the current on the iron during the time $\delta t$? The back E.M.F. in the magnetising coil is $N\frac{\delta \mathbf{B}}{\delta t}$; the current corresponding to $\mathbf{H}_2$ is $\frac{\mathbf{H}_2 l}{4\pi N}$; the product of these factors multiplied by the time is the work done, or

$$\text{work done} = \frac{\mathbf{H}_2 l}{4\pi N} \times N\frac{\delta \mathbf{B}}{\delta t}\delta t = \frac{\mathbf{H}_2 l}{4\pi}\delta \mathbf{B}.$$

Now when, during the time the current is falling, the induction diminishes by $\delta \mathbf{B}$ at the point Q, **H** is only $\mathbf{H}_1$, and the energy returned by the iron to the circuit carrying the current is $\frac{\mathbf{H}_1 l}{4\pi}\delta \mathbf{B}$, so that $\frac{l}{4\pi}(\mathbf{H}_2 - \mathbf{H}_1)\,\delta \mathbf{B}$ is lost in the iron. When $\delta \mathbf{B}$ is very small $(\mathbf{H}_2 - \mathbf{H}_1)\,\delta \mathbf{B}$ is the area of the little parallelogram P, Q; and as the whole cyclic curve can be divided into such little areas, the whole loss in the ring is

$$\frac{l \times \text{area of } \mathbf{B\text{-}H} \text{ curve}}{4\pi};$$

and since there are $l$ cubic centimetres of iron in the ring, the loss per cubic cm. is clearly

$$\frac{\text{area of } \mathbf{B\text{-}H} \text{ curve}}{4\pi} \text{ ergs. per cycle.}$$

It will be noticed that no distinction is made between the induction in the iron and the induction which would have threaded the coil if the iron were absent, thus departing from the highly artificial and confusing custom of dividing **B** into **H**, plus another quantity, the meaning of which in the case of a closed iron ring is not clear. To be consistent, those physicists who write $\mathbf{B} = \mathbf{H} + 4\pi\mathbf{I}$ ought, perhaps, when speaking of a copper wire carrying six amperes, to tell us, "the current in that wire is one ampere, which would be there if the wire were iron, plus five amperes 'induced' in the wire because it is not an iron but a copper wire." Or again, of a mica condenser, "that condenser holds five micro-coulombs at one volt; but it would hold one micro-coulomb if the mica were absent so that the total induced charge is only four micro-coulombs." Therefore its capacity is four microfarads!!

To resume. The area of the curve in Fig. 1 being 81,600, the loss per cub. cm. is $\frac{81{,}600}{4\pi} = 6{,}500$ ergs per cycle. The volume of iron is 13,700 cub. cm., the frequency 70, so we have for the *power* wasted on hysteresis,

$$W_h = \frac{6{,}500 \times 13{,}700 \times 70}{10^7} = 625 \text{ watts.}$$

(6) In this calculation we have made two assumptions, which we will now justify, if we can. First, we got the average E.M.F. by multiplying E by $\frac{9}{10}$, thus tacitly assuming the E.M.F. wave to be sinusoidal. The E.M.F. is tolerably certain to lie between the two limiting forms ⋀⋀⋀ and ⊓⊔⊓⊔; in the first or zig-zag, the proper coefficient would have been ·86; in the second, it would be 1; so that the 625 watts cannot be more than 4 per cent. too high, nor 10 per cent. too low; always supposing the generator to give a smooth curve of some sort. We need hardly observe that an error of 5 or 10 per cent. in estimating a loss will make practically no difference when we come to add up all the losses.

Next we assumed a **B-H** curve taken by the ordinary ballistic galvanometer methods to be a faithful representation of what goes on in a transformer core under rapid reversals of magnetic force. In taking **B-H** curves from laminated iron rings of small size, it is obvious that the time taken by the exciting current to reach, say, 98 per cent. of its steady value, must be very short; and, in fact, in obtaining the particular **B-H** curve used in the foregoing calculation, the current necessary to produce an induction in the ring equal to 10,000 gausses must have reached 98 per cent. of its steady value in about one-hundredth second, corresponding with a frequency of 25. This is sufficiently near the frequencies used in practice to make it in the highest degree improbable that the curve so obtained is seriously different from what it would be at three or four times the frequency. Moreover, Prof. Ewing's "model" having put the Weber-Maxwell theory of molecular magnets on a tolerably secure and simple basis, it certainly seems well-nigh incredible that molecular magnets should be incapable of executing forced vibrations at what must, from a molecular point of view, be a very leisurely pace.

(7) At this point we may just touch on the question of the so-called *viscous* hysteresis. It is alleged that quite apart from eddy currents and static hysteresis there is a true *time-lag* of induction behind magnetising force. Prof. Ewing has, indeed, observed a time-lag for very small values of **H**, the lag amounting to several minutes; but has such a lag as this anything whatever to with transformers? No, and for a very good reason. When a **B-H** curve is taken, as was that in Fig. 1, by the ballistic method, the galvanometer gives us the almost *instantaneous* value of **B** for any value of **H**, and these are the

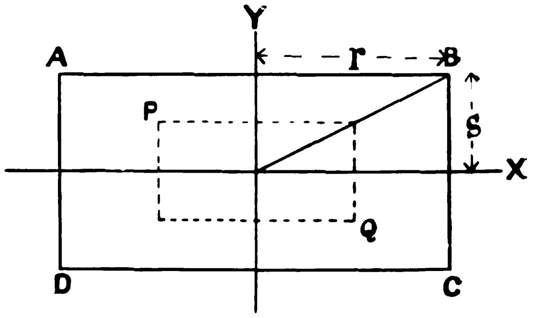

Fig. 2.—Section through Core Lamina normal to Induction Path.

values used in determining the hysteresis loss. As to a lag comparable with such short times as one-tenth to one-hundredth of a second, there is no evidence whatever of its existence, and never will be until eddy currents are entirely eliminated from experimental results.

It is interesting to note that the loss per cub. cm. per cycle in the iron used for the cores of these transformers is only 25 per cent. higher than that given by Prof. Ewing, so that in practice it is possible to get large quantities of excellent iron requiring no annealing before use.

(8) *Eddy Current Loss.*—In determining this loss in the core of a transformer, we are obliged to fall back on approximate calculation, as so far as the writer is aware no reliable experimental determinations have yet been made. In Fig. 2 let the rectangle A B C D be a section through a single lamina of the core, at right angles to the induction path. Assume the direction of the resultant E.M.F. and current in the lamina to be parallel to the edges of the section, then the dotted line P, Q will be an elementary current path cutting the axes at the values $+x+y$ and $-x-y$, in succession.

Let $\dot{\mathbf{B}}$ be the time rate of change of induction in the lamina, that is $\frac{d\mathbf{B}}{dt}$.

$\rho$ be the specific resistance of the iron.

$l$ be the length taken along the induction path.

Then the E.M.F. round P Q is, of course, $\dot{\mathbf{B}}$ (area P Q), or $4\dot{\mathbf{B}}xy = 4\dot{\mathbf{B}}\frac{s}{r}x^2$ by the assumption we have made with respect to the direction of E.M.F.

Digitized by Google

The resistance of the elementary path P Q is

$$dR = 4\frac{\rho}{l}\left(\frac{x}{dy} + \frac{y}{dx}\right) = 4\ \frac{\rho r x}{l s d x} \quad \text{or}$$

we can safely neglect the term $\frac{s}{r}$ in any lamina whose width is, say, 20 times its thickness. The element of power—

$$dw = d\ \frac{E^2}{R} = 4\dot{B}^2 \frac{s^3 l}{r^3 \rho} x^3\, dx$$

and the power in $l$ cms. of lamina is

$$W = \int_0^r 4\ \dot{B}^2 \frac{s^3 l}{r^3 \rho} x^3 dx = \frac{\dot{B}^2 s^3 l r}{\rho}$$

but as $s = \frac{t}{2}$ and $r = \frac{b}{2}$ expression is equivalent to

$$\frac{\dot{B}^2\, t^2.t\, l\, v}{16\,\rho}$$

for a volume of $t\,l\,b$ cms., and finally the loss is

$$\frac{\dot{B}^2 t^2}{16\,\rho} \quad . \quad . \quad . \quad (2)$$

watts per c.c. of iron in the core provided $\dot{B}$ is reckoned in volts and $\rho$ in ohms.

This is the loss on the assumption that the eddy currents are constrained to flow in lines parallel with the bounding surface of the lamina. Any artificial constraint of this kind must tend to diminish the calculated loss, so that the true loss will be slightly greater than that found from (2). To get a rough idea of the difference take the loss in a *square* wire. Calculated on the same supposition as to direction of currents that is involved in (2) it is $\frac{\dot{B}^2 l r^2}{8\rho}$ × (area of section), where $r$ is the radius of *a circle of the same area* as the square wire. It is clear that the true loss must be slightly *less* than in a round wire of the same area; that is to say, it must be less than $\frac{4\dot{B}^2\, l r^2}{\pi\, 8\, \rho}$ × (area of section), which is the calculated loss in a round wire of radius $r$. Now this last expression is got by assuming the current flow to be everywhere parallel to the boundary of the circular section, an assumption which is obviously correct, and therefore the actual loss in the square wire cannot be more than $\frac{4}{\pi}$ times the loss when the currents are constrained. In a thin lamina the "constrained" and the true loss must be very much nearer equality, for in a large proportion of the area of section the currents are constrained by the bounding surface. In short, the result given in (2) *must* be correct for infinitely thin laminæ, and is sufficiently accurate for all practical purposes. In order to err on the right side we shall make an allowance for the eddy currents in the solid bolts used for clamping the core plates together; an addition of 5 per cent. will cover this.

(9) When we come to put the values given in Table I. into equation (2) the inquiry naturally arises—is $\dot{B}$ constant throughout the section of a lamina? It is clear that $\dot{B}$ itself is not uniform, being least at the centre of the lamina, where the eddy currents have the greatest demagnetising effect, and before drawing a transformer diagram we must ascertain what extra $H$ is required to neutralise the negative $H$ due to eddy currents; in the meantime we cannot make an appreciable error in reckoning $\dot{B}$, that is $\frac{dB}{dt}$, from the secondary E.M.F. Thus, $\dot{B}$ = effective $\frac{dB}{dt} = \frac{100}{34 \times 95}$ = E.M.F. in volts per square centimetre of core, or $\dot{B}^2 = 9{\cdot}55 \times 10^{-4}$; $t^2 = 25 \times 10^{-4}$; $\rho = 10 \times 10^{-6}$, and the eddy current loss is $\frac{9{\cdot}55 \times 25 \times 1{\cdot}05}{16 \times 10 \times 10^2} = {\cdot}0156$ watts per c.c. This multiplied by 13,700 (the volume of iron in the core) is the total eddy current loss,

$$W_e = 214 \text{ watts.}$$

(10) *Eddy Currents in the Coils.*—One feels inclined to say there are none in a reasonably well-designed transformer. Such as there are, however, are due to the stray induction through the coils outside the core, including the induction in each wire due to its own current; the latter being the more important. This effect has been investigated by Sir William Thomson, who has calculated the loss of power expressed as increased resistance consequent on the varying current density in the wire, but we need not consider the loss of power from this cause in such wires as are used for transformer coils. No doubt, if a large solid wire were used for the secondary the loss might be appreciable, but the secondary of a transformer for 200 amperes would always consist of several small insulated wires wound side by side and coupled in parallel.

(11) *$C^2R$ Loss in the Coils* depends on the load; taking the transformer at full load the secondary current is 224 amperes, primary current 11·2 amperes for the load plus ·5 ampere for excitement, or say, roughly, 12 amperes. We have

$$C_s^2 R_s = 224^2 \times {\cdot}003 = 150 \text{ watts}$$
$$C_p^2 R_p = \ 12^2 \times {\cdot}98 \ = 142$$

The total drop in volts due to resistance of primary, plus that in secondary, amounts to about 1·25 per cent. at full load.

We can now write down all the losses and find the full load efficiency:—

**Table II.**—*Thirty Horse-Power Transformer.*

| —— | Watts. | Percentage of total power. |
|---|---|---|
| Full load output | 22,400 | 95·0 |
| Core, hysteresis | 625 | 2·7 |
| Core, eddy currents | 214 | ·9 |
| $C_p^2 R_p$ | 141 | ·6 |
| $C_s^2 R_s$ | 150 | ·8 |
| Total | 23,530 | 100·0 |

$$\text{Efficiency} = \frac{22{\cdot}4}{23{\cdot}5} = 95 \text{ per cent.}$$

(12) A large transformer like this would only be used in a sub-station, or on a tolerably constant load of not less than 10,000 watts, so that the designer did not consider its all-day efficiency on one or two hours only at full load. When efficiency at or near full load is the only condition to be observed, it is perfectly justifiable to use a large core and very little copper in order to secure cheapness, and accordingly we find in the case we have taken that of the total loss nearly four-fifths is in the core. Altogether this transformer is a good representative of its class—viz., closed type for full load; and it has served to illustrate the way in which the efficiency can be calculated.

(13) Perhaps the clearest way of indicating the differences between closed and open transformers will be to choose one of the closed type of medium size and investigate its efficiency on an average all-day load. Then in imagination pull it to pieces and reconstruct it with a view to getting a higher efficiency, next convert it without any change in its coils into an open circuit transformer, and finally turn it into a rough imitation of Mr. Swinburne's "Hedgehog."

**Table III.**—*Ten Horse-Power Closed Transformer.*

| | | | |
|---|---|---|---|
| Full-load output | = | 7,500 | watts. |
| Frequency = F | = | 70 | per sec. |
| Total volume of iron in core | = | 6,600 | c.c. |
| Sectional area of iron in core | = | 58·5 | cms. |
| Mean length of magnetic circuit | = | 112 | " |
| Width of plates = $b$ | = | 10·2 | " |
| Thickness = $t$ | = | ·05 | " |

| —— | Primary. | Secondary. |
|---|---|---|
| Volts | 2,000 | 100 |
| Turns on coils | 1,120 | 56 |
| Resistance | 3·8 | ·0094 |

In Table III. are given the dimensions, &c., of a Goolden-Ravenshaw 10 horse-power transformer, which shall serve

Digitized by Google

as the victim of this destructive kind of criticism. The core plates being the same thickness as those used for the 30 horse-power size, the hysteresis and eddy current losses will be simply proportional to the volume of iron used, provided the induction is the same. As a matter of fact the maximum **B** is 9,800 gausses; 2 per cent. less than in the 30 horse-power. This is too small a difference to be worth notice in finding the hysteresis loss, but 4 per cent. may be deducted from the eddy current loss since it varies as $\mathbf{B}^2$. The output and losses may now be easily reckoned by comparison with Table II. They are inserted here for future reference.

**Table IV.**—*Ten Horse-Power Transformer.*

| — | Watts. | Percentage of total power. |
|---|---|---|
| Full load out-put | 7,500 | 94·0 |
| Core, hysteresis | 302 | 3·8 |
| Core, eddy currents | 99 | 1·2 |
| $C_p{}^2 R_p$ | 58 | ·7 |
| $C_s{}^2 R_s$ | 53 | ·6 |
| Total | 8,012 | 100·3 |

$$\text{Efficiency} = \frac{75}{80} = 94 \text{ per cent. at full load.}$$

Drop in E.M.F. at full load = 1·4 per cent.

The efficiency at different loads is shown as a curve in Fig. 3. Note that at about $\frac{1}{3}$ full load it is still 80 per cent., so that

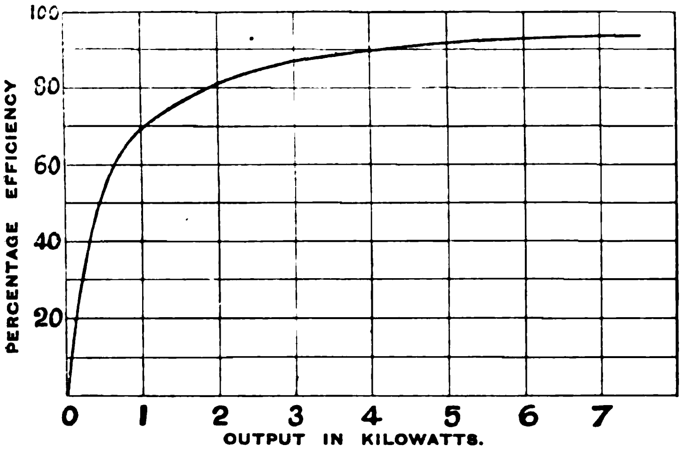

Fig. 3.—Efficiency-Output Curve of 10 H.-P. Ravenshaw Transformer.

where so large a constant load could be relied upon the transformer would be reasonably economical.

(*To be continued.*)

## PROBLEMS CONNECTED WITH INDOOR ILLUMINATION.

Physiological questions do not often come into the work of an electrical engineer, but the whole object of electric lighting, except from the photographer's point of view, is to stimulate the optic nerves of those who make use of it. Optic nerves have, indeed, been stimulated not wisely but too well, by naked arcs and badly arranged glow-lamps; and electric light has been condemned freely, and not unreasonably, as being injurious to eyesight, and, what is far worse, "unbecoming" to dresses and complexions. If electrical engineers could take up the position assumed by the electric supply companies, and restrict themselves to providing and distributing electrical energy, they would not be called upon to step out of their legitimate work. But those who are engaged in electric lighting have to supply lamps, and if these be glow-lamps, they can, at present neither get nor give any guarantee of their quality, efficiency, or life; and if arc lamps, they take refuge behind a "nominal candle-power," the ambiguity of which is largely due to the disparity between the illuminating power of the arc and of the standard candle in terms of which it is expressed. And with these lamps they have to provide the best illumination that they can. This optic nerve is, however, difficult to please, and it is not clear whether it alone is the arbiter, or whether the eye of which it is the essential part is to be satisfied, or whether, after all, the decision as to the quality and degree of illumination is to be referred to the judgment of the owner of the said eye. At any rate, the estimation of illumination comes to be a mere matter of opinion, and this, for several reasons, is much to be regretted. There will probably be a real objective standard of light before long; whether this will be supplied by a radiometer, a photo-electric cell, a photo-chemical eudiometer, or otherwise, we cannot yet predict. But of the illumination of a dining-room, a street, or a stage, we can never hope to have an accurate measurement in C.G.S. or any other units. We have a unit of illumination, and the result of a number of measurements were given in articles in *The Electrician* of August 15, 1890; but illumination measured quantitatively is not everything.

In electric lighting for domestic purposes, there is an æsthetic side of the question which must be considered. Difficult as it at first appears, it need not be approached by the engineer with so much caution as the wider æsthetic considerations of the design and treatment of fittings. Glow-lamps may be arranged for domestic use according to three different systems, and these are, of course, applicable to all other kinds of lighting, although the requirements are elsewhere not so exacting. The most luxurious and expensive method is that in which the lamps are screened from the eye, while they cast their light upon the walls or ceiling, and are thence reflected generally over the room. The ceilings being rarely, and the walls never of a pure white, and the reflecting power of their surface being small, a large amount of light must necessarily be wasted, and the effect is not good unless a considerable number of lamps are used, and are carefully arranged so that the illuminated surface is lighted with uniformity. This kind of illumination can without much difficulty be realised in a dining-room by throwing the light upon the table, while the lamps are carefully screened by a suitable shade, and we understand that if the screening is so well carried out that the guests do not realise that electric light is being used, this lighting is sometimes admitted to be "becoming." Where the illumination is not general, but special, as for lighting a particular picture, all that need be done is to place the lamp or lamps so that a tolerably uniform illumination is obtained without reflections from its surface, and with the lamps hid by reflectors. When the lamps are themselves visible, the question arises, shall they be subdued by more or less translucent shades, or shall they be allowed to shed their light direct?

The prejudice against arc lighting as a pleasant kind of illumination is too deeply rooted in this country to make it worth while discussing. True, we do not see so much of those pyrotechnic corruscations, those gleams of violet and flashes of blue, the fitful blink followed by a hiss and yellow flame that runs round the carbon; true, that we have arcs which are "absolutely steady" as compared with other arcs, and more steady than many gas burners; but great improvements must be made in both lamps and carbons before they can be admitted for interior use. But even with an "absolutely steady" arc, it is obvious that it would have to be screened by an opal globe to diminish the shadows and to prevent discomfort to the eye. For the same purposes, though to a much smaller degree, some such precautions must be taken with any light if it be more powerful than a candle, and it is strange that while a gas or oil burner is rarely seen in any situation where comfort and appearances are studied without some shade to soften the light, electric lights are too frequently used without any attempt whatever to diffuse the rays emitted by them.

General Webber recently extolled the advantages of 8-candle lamps over 16-candle, and condemned the use of "sunbeam" lamps for shop windows. He denounced "the other and

Digitized by Google

equally unreasoning extreme of procedure by which light is wasted foolishly in frosting bulbs, or enclosing them in obscured or coloured globes." Prof. Forbes, in the discussion made the extraordinary assertion that frosted, *i.e.*, ground glass globes, absorbed little if any light, and attributed the observed loss to dirt upon the surface. To discuss these statements in full would require several columns, and we will only allude to the chief points. The dazzling, which is so intense in an arc, is far less, but not absent from a 16-candle lamp, and whatever may be its value, it is only one half as great in an 8-candle lamp. Two 8-candle lamps, then, give the same light as one 16-candle, but with less dazzling, and if they can be placed at some distance apart, they will give a better distribution of illumination. But the first cost of wiring, and the cost of lamp renewals and risk of breakage are doubled. There are many cases where these considerations altogether outweigh any questions of comfort, and for many purposes the economy of a few powerful lamps is so great that it is worth while studying means for securing a certain degree of comfort without incurring needless expense. The use of powerful argand gas burners enclosed in brilliant reflectors is familiar to everybody. They are most inconvenient excrescences for the passer-by, and when electric light is used, there is less occasion for putting them out of doors. To induce shopkeepers to use glow-lamps, we should certainly recommend the use of lamps not less than 32 candle, screened from direct view, either by metallic or thick opal reflectors. So far do considerations of comfort weigh with some persons, that it has even been urged that a given number of 16-candle lamps may be replaced by 8 candle without affecting the illumination. We will readily admit that a better distribution might be obtained by the use of 30 8-candle lamps, instead of 20 16-candle lamps, although the aggregate light would be less; but to assert that the illumination, say at the Society of Arts (where the lamps are so high up that dazzling need not be considered), would be the same if the candle-power of each lamp were reduced to one-half, is too absurd a statement to require refutation. But apart from the facilities for better distribution of light, the demand for frosted bulbs arises from the same causes as the preference for 8-candle-power lamps, viz., there is less dazzling. If the reduction of size were carried far enough, there would be no need for frosting, and the ideal lighting of a well-decorated room, by wax candles, might be closely imitated by employing an immense number of small lamps.

But leaving the question of illumination, and coming to matters of comfort, we are on the verge of, if not beyond, the limits of the business of an engineer, and we will only briefly allude to the means, and say nothing of the ends attained. Prof. Forbes must have been deeply plunged in purely scientific speculation when he said that ground glass practically did not obstruct light. He described ground glass as consisting of a mass of prisms and reflecting surfaces, and suggested that since the glass was really clear, the light really got through after all, though it suffered somewhat from internal reflection. This is plausible enough in an *a priori* way, but the simple fact remains that a sheet of ground glass, or a frosted bulb, is found on the photometer to show an absorption of about 20 per cent. We have indeed found in one sample an absorption of only 16 or 17 per cent., but it frequently reaches 25 per cent. Now the interesting and scientific part of the question would be to discover where the light *does* go. A plain sheet of glass obstructs nine or ten per cent. of the light, and the loss takes place in three different ways: firstly, and most important, the reflection at the first surface; secondly, the absorption in the glass through imperfect transparency; and lastly, internal reflection at the second surface. The first two are unaltered with glass ground on the second surface, but here the loss by internal reflection is much greater, for the angles of incidence are greater. Probably only one-half of the light passes directly through, losing nothing by mere refraction, but the other half gets tossed backwards and forwards by internal reflections, and not much more than a half of it gets through at all. To make a measurement, the lamp must be wholly surrounded by ground glass. A flat screen will appear to absorb 30 per cent., because it diffuses the light in directions other than towards the photometer. Every photographer knows that there are very different qualities of ground glass, and that a very coarse or very fine grain each approximate to clear glass. A cut glass shade spun rapidly in front of a photometer will absorb about the same proportion as ground glass; no useful measurement can be made when it is stationary, as a plane facet may happen to let light pass direct, or a prism may increase or reduce the illumination on the photometer screen. A very beautiful lamp was invented by Mr. L. J. Crossley, in which half the bulb was opal, and though the naked filament was visible, it largely reduced dazzling, since it was seen against a bright, not a dark background; but, for reasons connected with the lamp monopoly, it has not been placed on the market. Silk shades get dusty and fancy glass looks tawdry by daylight, but anything is better than a naked 16-candle lamp, backed, perhaps, by some glaring copper or ormolu fitting.

The whole subject is one which we think might well be taken up by some architect. Members of this kindred profession have done great service by the design of original and convenient fittings, and useful mouldings and casings. Engineers will do all they can to make electric light safe and cheap; let some artistic genius make it comfortable and beautiful. Few statements are so detrimental to the progress of the industry as the half-truth—electric light is bad for the eyes.

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**FRIDAY, February 20th.**

INSTITUTION OF CIVIL ENGINEERS.

*2 p.m.* Students' Visit to the Tower Bridge Works.

SOCIETY OF ARTS.

*4.30 p.m.* Popular Afternoon Lecture: "The Science of Colour," by Capt. ABNEY, F.R.S.

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse: "Infectious Diseases, their Nature, Cause and Mode of Spread," by Dr. ED. E. KLEIN, F.R.S.

**SATURDAY, February, 21st.**

ROYAL INSTITUTION.

*3 p.m.* Afternoon Lecture: "The Forces of Cohesion," by Lord RAYLEIGH, F.R.S.

**MONDAY, February 23rd.**

SOCIETY OF ARTS.

*8 p.m.* Cantor Lecture III. 2. "The Electric Transmission of Power," by GISBERT KAPP.

**TUESDAY, February 24th.**

ROYAL INSTITUTION.

*3 p.m.* Afternoon Lecture: "The Structure and Functions of the Nervous System," by Prof. VICTOR HORSLEY, F.R.C.S.

INSTITUTION OF CIVIL ENGINEERS.

*8 p.m.* Ordinary Meeting. Paper to be further discussed: "Electric Mining-Machinery," by LLEWELYN B., and CLAUDE W. ATKINSON, A.M.I.C.E. Paper to be read, time permitting: "On the Subterranean Water in the Chalk Formation of the Upper Thames, and its Relation to the Supply of London," by JOHN THORNHILL HARRISON, M.I.C.E.

**WEDNESDAY, February 25th.**

SOCIETY OF ARTS.

*8 p.m.* Ordinary Meeting. Paper to be read: "Colonisation and its Limitations," by E. J. RAVENSTEIN.

**THURSDAY, February 26th.**

INSTITUTION OF ELECTRICAL ENGINEERS.

*8. p.m.* Ordinary General Meeting.

**FRIDAY, February 27th.**

SOCIETY OF ARTS.

*4.30 p.m.* Popular Afternoon Lecture: "The Science of Colour," by Captain ABNEY, C.B., F.R.S.

PHYSICAL SOCIETY.

*5.30 p.m.* Ordinary Meeting. Papers to be read: "Proof of the Generality of certain formulæ published for a special case by Mr. Blakesley." "Tests of a Transformer," by Prof. W. E. AYRTON and J. F. TAYLOR. "Further Contributions to Dynamometry," by T. H. BLAKESLEY. "Note on Electrostatic Wattmeters," by J. SWINBURNE. "Interference with Alternating Currents," by Prof. W. E. AYRTON and Dr. W. E. SUMPNER.

INSTITUTION OF CIVIL ENGINEERS.

*7.30 p.m.* Students' Meeting. Paper to be read: "Disintegrators," by BERTRAM CHATTERTON, S.I.C.E.

ELECTRO-HARMONIC SOCIETY.

*8 p.m.* Ladies' Night. Concert in St. James' Hall Restaurant.

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse: "The Art of Acting," by PERCY FITZGERALD, M.A.

Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*" *All other letters to be addressed to the Editor.*

*All letters intended for insertion in* "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

*New Volumes of* "THE ELECTRICIAN" *commence in May and November.*

## SUBSCRIPTION RATES.

**The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—**

| | 3 months. s. d. | 6 months. s. d. | 12 months. s. d. |
|---|---|---|---|
| For the United Kingdom | 5 0 | 10 0 | 19 6 |
| For Foreign Parts and Colonies:— Within Postal Union | 6 6 | 12 6 | 24 0 |
| For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar | 7 6 | 14 6 | 28 0 |

## TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

*Particulars relating to Advertisements will be promptly forwarded on application to the Offices as above.*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday morning. Renewals of expiring advertisement orders and alterations to standing advertisements should be in the Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday evening.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xvii.) are accepted up to 4 p.m. on Thursday.*

## TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a large Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electro-Technical Literature, &c.*

## "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

*Early in each year is issued* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1891 Edition, published on the 23rd February, consists of 900 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

*Order at once. Price 5s., post free 5s. 9d. Abroad postage extra. Full particulars on application.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

*All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of* "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

## CONTENTS OF THE CURRENT NUMBER.

NOTES ... 471
The Magnetic Circuits of Transformers: Closed versus Open. By S. Evershed. Illustrated 477
Problems connected with Indoor Illumination ... 480

City Notes, &c. ... 499

## STEEL-PLATE PORTRAITS

*Of W. H. Preece, F.R.S.; Michael Faraday; Sir John Pender, K.C.M.G.; Sir William Thomson, F.R.S. (Past-President of the Institution of Electrical Engineers); C. H. B. Patey, C.B. (Late Secretary of Telegraphs, G.P.O.); Dr. John Hopkinson, F.R.S. (Past-President of the Institution of Electrical Engineers); Dr. Oliver J. Lodge, F.R.S., and Prof. William Crookes, F.R.S. (President of the Institution of Electrical Engineers), have been issued as Supplements to* "THE ELECTRICIAN." *A few Copies of these admirably-executed Steel Engravings can be supplied, price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, post free, 4s. 6d.*

## THE LONDON COUNTY COUNCIL AND TECHNICAL EDUCATION.

The debate on Technical Education which took place at a meeting of the London County Council last week afforded one of those rare occasions on which an important public question can be discussed in that assembly without political bias or party animosity. On the whole the meeting contrived to rise to the level of the subject; and with the exception of an acrimonious fling at the City Companies the discussion was pursued with fairness and an evident desire to arrive at a wise decision. The matter is not yet finally disposed of; and the narrow majority by which Mr. BENN's amendment was carried may probably give rise to the whole subject being reconsidered. But the general line of difference which separated the supporters and opponents of the Committee's Report on Technical Education is sufficiently clear to enable us to appreciate their positions, in spite of a disturbing element to which reference will be made presently. It will be remembered that a windfall in the shape of the new Beer and Spirit taxes dropped from the hands of Mr. GOSCHEN last year into the lap of the County Council, who appointed a special committee to report as to the disposal of the gift, which amounted to £23,000, and which will be continued year by year without abatement, and probably with increment. The Committee have made their report, in which they recommend

Digitized by Google

the application of the fund to the purposes of technical education in London, apportioned among ten institutions in sums varying from £4,000 to £500—the existing Polytechnics of the Borough-road, of Battersea, and of Regent-street receiving each the larger of the sums just named. It was further proposed that a Standing Committee on Technical Education be created to report upon the application of these subventions, and generally to determine their amounts from time to time. It is this report that the London County Council has had under consideration; and although they may be disappointed with the immediate result of its vote, the friends of technical education, we cannot help thinking, in the long run will be satisfied with what has occurred.
